Somerset—Somerset County is the scene of great activity along electrical lines. The Penn Electric Service Co., which has absorbed a number of smaller concerns in Somerset and adjoining counties during the past several years, is bending its energies toward the completion of high-tension transmission lines. The lines will carry current for light and power on a large circuit, which will include many of the principal towns and coal companies of the county. It is expected that the Somerset loop will be completed by fall. The route is from Johnstown to the new mining town at Cairnbrook and several other little mining towns. Other towns will be connected next year. These will probably include the mining towns of Rockwood, Garrett, Meyersdale and Salisbury.

Colver—The Colver drift is now averaging between 3500 and 3800 tons of coal per day, the rated capacity being 4000 tons. More rolling stock and other new equipment is being purchased, and this will probably bring the output up to its full capacity. Reports have been circulated concerning the opening of a new mine, but these are unconfirmed.

Wehrum—Four hundred miners will be temporarily out of employment as the result of a fire at the plant of the Lackawanna Coal & Coke Co.

WEST VIRGINIA

Charleston—Announcements have been made by the Department of Mines that examinations for mine foremen and firebosses will be held at Welch, Sept. 15 and 16; at Logan, Sept. 23 and 24; at Mt. Hope, Sept. 29 and 30; at Charleston, Oct. 6 and 7, and at Grafton on Oct. 13 and 14.

Accident returns for the month of July showed that, despite the fact that some of the miners of West Virginia are still risking their lives by violation of state mining laws and the rules of the company, the number of fatalities is decreasing. As in previous months, many miners who violated rules, lost their lives thereby. Thirty-three men were killed in the state during July, as against 41 for the month of June.

Fayette—For the purpose of raising funds with which to install new electrical machinery, the Lynchburg Colliery Co. and the Deity Colliery Co., on Gauley, have given deeds of trust on the property to H. A. Robson, of Charleston, and C. L. Christian, of Lynchburg, trustees, to secure a loan of $65,000. Of this sum, $30,000 is for the Lynchburg operation and $35,000 for the Deity company. The installation of the new electrical equipment will make the mines the best equipped properties on Gauley.

ALABAMA

Birmingham—Henry L. Jackson, administrator of the estate of Claude N. Jackson, has filed suit against the Brilliant Coal Co. for $50,000 damages for the death of the latter, who was recently killed while in the employ of the above company. This is one of the largest suits ever filed in this district for the death of an individual.

Edgewater—The Tennessee Coal, Iron & R.R. Co. has just appropriated $5000 for improvements to its bath house. This bath house is acknowledged to be one of the most modern and complete in the United States, and the above appropriation is for enlargement.

TENNESSEE

Coalfield—The Coalfield Coal Co., employing about 50 men, has closed down its mines for a period of 90 days on account of an utter lack of orders. The mines have been running on short time for several months, but this is the first time in years that they have been shut down altogether.

Vasper—The Vasper Coal Mining Co., organized some time ago, it is stated, has begun to open mines on its holdings of 1000 acres. Plans for machinery have not yet been decided upon. C. P. Harley is president and T. C. Jacks, secretary and manager.

KENTUCKY

Barbourville—Coal-mine operators in this section are confronted with a labor shortage, numbers of Hungarian and Austrian laborers having departed for the coast with the intention of sailing for home, provided they can get passage, to report for service in the armies. Mines are running to capacity hereabouts and a big increase is expected if the war in Europe is to be prolonged.

Lexington—Coal traffic over the Louisville & Nashville R.R. will be greatly expedited by the belt line which the Louisville & Nashville has just completed. The line connects the Lexington & Eastern branch with the Cincinnati and Louisville lines, and will not only save mileage, but will obviate the necessity of switching coal trains about in the city yards. The line, with the right of way, involved an expenditure of about $40,000.

OHIO

Bailey's Mills—The Dixler & Ohio Coal Co. and the Coalburg Co. have signed an agreement with the men employed b ythem under which the 47c. scale demanded by the union will be allowed. Preparations are under way for the resumption of work at the two mines, which employ about 250 men.

Massillon—The Massillon Coal Mining Co., the largest producer in the Massillon district, has placed three of its mines in operation. It is also announced that three new shafts will be operated late in the fall. Over 1500 men will be employed.

Logan—The first shipment of coal made by the Coonville mines of the Starr-Hocking Co., since the mines went into the hands of a receiver, was recently made. The financial affairs of the company are being adjusted, and it is the prevalent feeling that better times are ahead.

Columbus—Application has been made before the Ohio Utilities Commission for permission to waive the collection of demurrage charges and the suspension of car service rules on fine coal. This was done because of the lack of demand for the small sizes.

All of the sales agents and district managers for the New York Coal Co. made an inspection trip of the mines of the company in the Hocking Valley and the washery, Aug. 22. They were under the charge of C. W. Thompson, secretary, and J. A. Teegardin, sales manager. It is the plan of the company to apportion the output of the washery among the various salesmen.

Congo—State Mine Inspector J. M. Roan, assisted by a number of deputies, opened the Congo mine of the Sunday Creek Co., last week. The mine caught fire several months

ago, and was at that time sealed up under the direction of the mine department. It was found that the fire had burned itself out, and the mine will be placed in condition to operate.

INDIANA

Terre Haute—A trust deed given by the Grant Coal Mining Co., of Chicago, to the Drovers National Bank in that city, for $125,000, has been recorded here. It is for 6 per cent. gold bonds, payable $5000 May 1, 1915, and $20,000 annually thereafter.

The Jackson Hill Co. is sinking a new mine northwest of this city. A switch is being laid to the Miami Coal Co.'s new mine in the same territory. The court decided against those property owners who held that their land could not be condemned for railroad right-of-way for a mine switch only, and not for regular railway traffic.

It has been decided not to merge the miners of the bituminous and block fields of Indiana.

Clinton—The Miami Coal Co. has changed its headquarters from Brazil to this city.

ILLINOIS

Springfield—It is estimated by Duncan MacDonald, secretary-treasurer of the United Mine Workers, that 10,000 miners are out of work in the state. There appears to be no great prospect for decided betterment in the industry, and many of the workmen are crowding into other lines of labor and are not waiting for the fall work to commence.

Carlinville—The injunction suit of the Carlinville Coal Co. against the Ohio Oil Co. has been adjusted at the cost of the defendant. The Oil company stipulated that it will do no more drilling in this vicinity, and practically none on any portion of the complainant's coal field.

Pana—A small but troublesome fire recently broke out in the casing of the Penwell coal mine shaft, and for a time promised to give a hard fight. The city fire department, however, got it under control in about half an hour.

Cambria—The entire top works of the Donnelly-Koenecke Coal Co. was recently destroyed by fire, with no insurance. The loss on the rescreening plant and on the other property will amount to between $40,000 and $50,000. This property went into the hands of a receiver last winter, W. O. Potter, of Marion, being appointed to take charge of the property, which has been idle since that time.

Johnston City—The Lake Creek mine, near here, owned by New York parties affiliatd with the Cotton Belt R.R., and the output of which for the past year or so has been taken entirely by that railroad, is now equipped to ship commercial coal.

COLORADO

Denver—In a suit filed in the United States District Court, the government charging that the estate of Allen M. Ghost is holding 836 acres of coal land in Las Animas County illegally obtained in 1901 by Ghost and associates. This land is now considered to be worth over one million dollars, and the government asks that the patents be cancelled.

FOREIGN NEWS

London, England—It is stated that in spite of the removal of the embargo on exports of coal, the business is almost at a standstill, owing to the high freight rates. Sellers are demanding at least partial cash payment.

News comes from Bern, Switzerland, that notwithstanding the assurances that Germany is provided with plenty of coal, it is known that women are being put to work in the collieries of the Rhenish provinces.

PERSONALS

H. P. Dowler, formerly superintendent of the coal operation at Heilwood, Penn., is contemplating starting in coal mining for himself.

Michael Hartneady, sheriff of Carbon County, Penn., was recently re-elected president of the United Mine Workers of the Panther Creek Valley.

J. H. Bovard, president of the Northwestern Coal Co. and general manager of the Farmers' Coal Co., at Kansas City, is at business again after four weeks in a hospital for an operation. He is recuperating rapidly.

W. J. Richards, president of the Philadelphia & Reading Coal & Iron Co., recently visited Boston and inspected the various re-handling plants of his company. He was accompanied by R. J. Montgomery, general coal agent.

Thomas R. Keating, assistant mine foreman at No. 4 shaft of the Ewen colliery, Pennsylvania Coal Co., has severed his connection with the company to accept a position as general superintendent with the Mohawk Coal Co., of Carbondale.

John Conlon, mine foreman for the Delaware & Hudson Coal Co. in Plains Township, has started the erection of a new breaker to conduct secondary mining operations in that township. The old Union slope is the section to be mined, it being stated that large quantities of coal still remain in the operation, which was abandoned years ago before more improved methods of mining were practiced.

CONSTRUCTION NEWS

Kittanning, Penn.—The Queenstown Coal Co., which has been engaged for some time in opening its mine in Brady's Bend Township, is now about ready to begin the shipment of coal.

Bentleyville, Penn.—It is expected that the Montour R.R. will have trains running over its new line by Sept. 15. The road is about completed and what construction work remains to be done can be finished in about a month.

Blairsville, Penn.—A contract has been awarded by the Pennsylvania R.R. Co. for the construction of a three and a half mile single-track extension of the Homer & Cherry Tree branch, to tap some new coal lands in Indiana County.

Winchester, Ky.—The Winchester-Irvine extension of the Louisville & Nashville R.R. has been completed from here to Red River, a distance of 14 miles. Construction work has progressed rapidly on the other side of the river, between there and Irvine, and it is expected that steel will be laid into Irvine shortly. There is about a month's work on the Red River bridge. This branch will open up a rich coal territory.

Henderson, Ky.—Officers of the Deepwater Coal Co., with engineers, are examining sites in Henderson and across the Ohio River, in Evansville, for the projected manufacturing plant of the Ohio & Mississippi Valley Barge Co. This latter firm, it is alleged, is to construct barges, to convey the coal of the Deepwater company from the mines in Kentucky, to the Gulf of Mexico. Surveys of the river front are being made.

NEW INCORPORATIONS

Tuscumbia, Ala.—The Southern Mining & Milling Co. has been incorporated with a capital stock of $100,000.

Birmingham, Ala.—The Margaret Coal & Sales Co. has been incorporated, with a capital stock of $2000. Charles DeBardeleben is named as president, W. W. Fulghum secretary-treasurer, and W. C. Adams, sales manager.

Charleston, W. Va.—The Jackson Coal Co. has been incorporated with a capital stock of $5000, which will probably later on be increased to possibly $600,000. The incorporators are F. J. Harry, H. W. DePue, J. S. Scott, L. S. Echols and Mrs. L. S. Echols.

Charleston, W. Va.—The Superior Block Coal Co., of Beckley, has been organized with a capital of $65,000. This firm will operate in the Duvall district of Lincoln County. The incorporators are G. C. Helrick, B. J. Shumate, John Anderson, G. H. Spalding and John Morris, all of Beckley, W. Va.

INDUSTRIAL NEWS

Pittsburgh, Penn.—Ernest Borra and Joe Barline, miners, of Bridgeville, on Aug. 21, pleaded guilty in Criminal Court to a charge of violating mining laws, in that they tamped shots with coal dust instead of clay. Sentence was suspended on payment of costs.

Peoria, Ill.—Judge Leslie D. Puterbaugh has been appointed receiver for the Horace Clark & Sons Co., mine operators. The application for the receiver was made by the Philadelphia & Reading Ry. Liabilities are listed at $330,000, with assets estimated at $650,000.

Pittsburgh, Penn.—I. W. Seamans has brought suit against J. A. Hillman & Sons Co. to recover $162,750 alleged to be due because a tract of coal sold to Seamans shows to be 70 acres short of 240 acres, the number he supposed he was getting, and which was all mineable.

San Francisco, Cal.—The tramp steamer "Mazatlan," which has flown variously the Mexican and German flags, was forbidden, Aug. 20, to leave port until she discharged 500 tons of coal in sacks, which it is alleged was intended to be transferred to the German cruiser "Leipsic," at sea.

Chicago, Ill.—Officials of the Illinois Central R.R. are making a tour of the United States and Canada, with the hope of finding a solution for the problem of storing bituminous coal. The company is seeking a method of storage to prevent deterioration and the danger from spontaneous combustion, also excessive costs in handling.

Venice, Italy—It is stated that all kinds of trades, steamships and railways in Italy are suffering from a shortage of coal. Nearly all the fuel used in Italy comes from England, and although the British Government has given permission for coal to be sent, English shippers have not complied, probably feeling that the Italians cannot pay cash.

Columbus, Ohio—The Ohio Utilities Commission has granted the request of the Hocking-Sunday Creek Traction Co. to issue $300,000 twenty-year bonds for the purpose of building and equipping the line from Chauncey to Athens. The line will then be opened between Nelsonville and Athens. It is planned to extend the line to Lancaster along the canal bank.

Cincinnati, Ohio—Orders have been placed by the receivers for the Cincinnati, Hamilton & Dayton R.R. Co. for 35 new locomotives to be used in hauling freight trains. The equipment of the company is in bad shape, and these locomotives will be used to bolster it up. Of the order, 30 are of the large Mikado type, and the remainder are smaller engines.

New York, N. Y.—The bituminous coal export market received a decided impetus Aug. 22, with the announcement that the Spanish interests at Madrid had made contracts for the delivery in Argentine and Uruguay of 3,800,000 tons of steam coal to be delivered over a period of two years at Buenos Aires, Montevideo and Rosario, and as rapidly as vessels can be procured to carry it.

Cincinnati, Ohio—The receivers of the Cincinnati, Hamilton & Dayton R.R. have ordered from the Mt. Vernon Car Co., 1000 box cars, and have also placed an order with the Cambria Steel Co. for 1000 gondola cars. It is understood, however, that these orders are made conditional upon the successful completion of arrangements for financing the road early this fall.

New York, N. Y.—Coal exporters only recently began to take advantage of the war to send fuel to Europe by way of the Mediterranean ports. On Aug. 19, the "Sweden," a neutral vessel, cleared with 6800 tons of coal. It is believed that more boats from neutral countries will be received here and the end of the war will probably find that the United States has a large export trade of coal to the Mediterranean countries.

Bluefield, W. Va.—The Norfolk & Western's official statement of coal carried during the month of July, 1914, is as follows: Pocahontas field, 1,314,478 net tons; Tug River, 263,240; Thacker, 288,643; Kenova, 100,600; Clinch Valley, 140,751. Other Norfolk & Western territory, 2735 net tons. From the Williamson and Pond Creek roads, 90,819 tons, and from all other railroads, 301,796 tons, making a grand total of 2,503,062 tons. This is 33,445 tons less than was shipped during the corresponding month of 1913.

Kansas City, Mo.—The Boycourt Coal Co. was the subject of involuntary bankrupt proceedings in the federal court at Kansas City, Aug. 20, the petitioners being Samuel Feller, the Baker & Lockwood Tent & Awning Co. and the Richards & Conover Hardware Co. The allegation is made that the State Bank of Ottawa, Kan., acquired $22,000 of stock of the company, under an agreement to pay the company's obligations, receiving a mortgage on the mines, and paid $6000 of the debts.

Washington, D. C.—The report of the Department of Mines, recently made public, states that 180 men were killed in and about the coal mines of the United States during the month of June, as compared with 192 during the same month of 1913. The number of fatalities in the coal fields of Pennsylvania was: Anthracite, 43; bituminous, 34. During the six months ending June 30, 1914, 288 men were killed in the anthracite region and 206 met death in the bituminous field. During the corresponding month of 1913, 336 men were killed in the hard coal field, and exactly the same number in the bituminous field of the state.

Coal Trade Reviews

General Review

Heavy all-rail shipments in anthracite and business is moderately active already. Eastern bituminous situation still improving. Orders and shipments for foreign markets are being reported. Trade slowly expanding and will be active shortly. Lake shipping better.

The anthracite trade is characterized by an unusually early buying movement that has created an excellent undertone and placed the market in a strong position. This is still confined mostly to the interior points, which continue absorbing unexpectedly heavy tonnages; naturally this has eliminated the possibility of any accumulation at Tidewater, which has also participated in the general improvement. The better demand has resulted in an increased working schedule at nearly all collieries, which is most unusual this early in the season.

The bituminous situation at Tidewater is still distinctly mixed and no definite developments of any kind have occurred. In spite of many reports to the contrary, there is no doubt that substantial tonnages of new business have been negotiated as a result of the European war, but it is equally true that this has caused a stoppage in other channels. As a rule the markets are not quotably changed, although rumors of substantial premiums are heard on export business. An interesting development of the week in the export trade was the clearing of a cargo from Hampton Roads for Stockholm, the first shipment ever made to that point. It is also a significant fact that the Hampton Roads piers worked last Sunday for the first time in a year. There is feeling that the domestic market is gradually broadening and a firm situation is anticipated in the very near future.

The exhaustion of consumers' stocks has forced additional buying and created a slightly better situation in the Pittsburgh district; prices continue irregular. Canadian buying is slowing down somewhat in all lines except the railroads which appear to be taking on extra supplies; rumors are current that much of this coal will eventually find its way into the British navy, but this is emphatically denied in official circles.

Though the effects of the general slowing up as a result of the war are being felt in the Ohio fields, the improvement in the Lake trade has steadied the market up in good shape. The Lake movement is now at the maximum of the year. Some local buying is being done, and operations in the mining districts are being accelerated.

The Southern trade is feeling the effects of the adverse conditions prevailing in cotton so that the market is irregular at the moment, though the outlook is bright. Heavy sales of pig iron indicate a strengthening in the industrial situation, and prices are showing a rising tendency. Middle-Western operators are firm in their convictions of a stronger market shortly, in spite of the interruptions incident to the war. The improvement is particularly noticeable in the domestic grades, the steam market showing a weakening tendency. Business so far is about normal for this period of the year.

ATLANTIC SEABOARD

BOSTON

Hampton Roads market steadily strengthening. Consignees are taking supplies freely. Pennsylvania grades develop an active business and Georges Creek shippers are well supplied with orders. Water freights hold recent gains. Anthracite fall prospect excellent.

Bituminous—The situation of Pocahontas and New River shows steady improvement. Prices are firm and the market is strengthening. Rumors are heard of what might be called "fancy prices" for export, but so far, confirmation is lacking. There can be no question, however, that the market will broaden materially during September. The Norfolk piers worked all day last Sunday, the first time in more than a year, due to the large number of steamers awaiting berth.

In New England, cargoes at the distributing points are being more freely absorbed; so far as reported, the on-car prices established a few weeks ago still prevail, and the trade is generally in a healthy state. Arrivals are heavier, the corporations apparently taking on coal as fast as storage will permit. The upward trend in water freights has also somewhat accelerated the demand from smaller buyers, but no real spot market for cargo lots has developed as yet.

The more popular grades from Pennsylvania are showing a spurt. Orders are beginning to accumulate with most of the operators, a pleasant contrast with conditions a month or two ago. Prices are hardening, although no pronounced movement has so far been in evidence. Some of the foreign ports that have hitherto shipped exclusively from England are likely to learn something of the merits of coals from the Pennsylvania districts as well as those from West Virginia. The lower-priced grades are also improving in demand.

There is no change to report in the Georges Creek situation. The shippers are well supplied with orders and the movement to New England is regular and in fair volume.

Water Freights are holding to the quotations of a week ago and owners still decline to name rates more than a few days in advance. All kinds of tonnage are in good request and the transportation interests are optimistic over the outlook.

Anthracite—The European war and the higher prices on other commodities have started the retail demand much earlier than usual. This is apparently true all over New England, although it is hard to foresee any upset in anthracite that can possibly result from the war. Stove size is in notably short supply with a number of the shippers, and certain of the steam sizes are also shortening up. The prospect is excellent for fall business.

Quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*.....	$0.90@1.50	$1.25@1.70	$1.67@1.77

NEW YORK

Bituminous shows a better tone. Estimated that 350,000 tons of new business has been closed since the war began. Mines working better. Anthracite trade opening up in excellent shape. Prices stiffer.

The Bituminous situation shows a slight improvement over that prevailing a week ago. The spot demand appears to be a little better and in some cases prices for prompt delivery are five cents per ton higher. The greatest stagnation is in bunker coal and that has improved so far as tramp steamers is concerned, although not yet normal by any means. The delivery to foreign ports is also below normal, though the situation appears to be clearing steadily. So far there seems to have been about 350,000 tons of new business booked for foreign shipment and steamers are commencing to report for loading.

Many inquiries are in the market for future shipment both for foreign and local delivery. As a rule shippers are inclined to look askance upon this class of business, confining their sales to prompt shipment, although at the same time some considerable tonnage has been closed on contract during the last week or two at usual figures.

Mines in most instances are working better, many of them nearly full as against half time in July. Others are

not doing so well, having a class of business which has been effected adversely through the war situation. Labor is still plentiful and cars in good supply with the exception of one or two r ads, that are filled up with loaded cars.

The outlook is good and shippers are still hopeful of seeing a very heavy demand at better prices within the near future. The market is quotable as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.55@2.65; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

In Anthracite the market continues to show an improved tone. At present the demand is good, particularly on the line, for all sizes, and mines are working full time without any trouble in moving the product. Stove is still the active size and the supply is not equal to the demand; it is the means of moving some of the other sizes that have accumulated at the piers during the recent dull period.

Small sizes are moving well, the better grades being actually short in several instances. Prices vary according to quality, but in no case does there seem to be any accumulation.

Quotations are now as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	$4.60@5.00	$4.95	$4.55@4.95
Egg	5.25	5.15@5.25	5.20	5.00@5.20
Stove	5.25	5.25	5.20	5.20
Chestnut	5.50	5.30@5.50	5.45	5.25@5.45
Pea	3.55	3.45@3.55	3.50	3.25@3.50
Buckwheat	2.80	2.75@2.80	2.50@2.75	2.15@2 75
Rice	2.30	2.25@2.30	2.00@2.25	1.70@2.25
Barley	1.80	1.75@1.80	1.75	1.30@1.75

BALTIMORE

Less coal on sidings following resumption of heavy bunker trade. Sales at the mines slow and prices continue flat. Anthracite conditions listless.

There is a decided improvement as regards the amount of coal awheel here and on demurrage. A big grain fleet has been moving out of Baltimore for the past week, and with it went a large quantity of coal in bunkers. This has proved a distinct aid to the local situation, and there is now little talk of sacrificing at tide.

Mine conditions are slow. Poor demand toward the Lakes, a general industrial flatness, including almost a complete suspension in much of the cement trade and the steel business, stand as the underlying causes. Three-quarter gas is selling in West Virginia around 90c.; slack is freely offered to the trade at the mines at 50 and 55c. Steam coals are a little better, calling for from 95c. to $1. Best grade Pennsylvania coals hold firm around $1.35, but there has been sacrificing of small lots; a sale on the latter basis of a well known high-grade coal was noted this week at $1.15. Poorer grades are selling at from $1 to $1.10.

The Export trade remains an almost negligible quantity. After a few shipments a week ago, there was a decided lull. Foreign purchasers, mostly through London connections, are making cable inquiries, but the fact that no cash exchange has been arranged for this side is apparently holding up a business that will probably develop a little later.

Anthracite dealers generally are complaining of dull times. Few deliveries of any consequence are being made. The trade is living in hopes that September will bring a change of conditions.

Coastwise Chartering is light, most of the movement being in company-owned colliers or on long-time charters. Free offerings to New England ports have established a low rate in that direction. Offerings for Southern hauls are rather scarce and rates are higher in proportion. The approach of the hurricane season is showing its influence there.

HAMPTON ROADS

Large shipments, foreign and coastwise, and inquries are still coming in. Government takes 12,000 tons. Prices remain at circular.

Shipments, both foreign and coastwise, are good. The number of bunker vessels has not been large, but under the existing war conditions, bunker loadings show up fair.

Inquiries are in the market for large quantities of coal for export, and bids have also been asked for supplying 3000 to 12,000 tons of bunker coal to United States transports now at Newport News. The inquiries for export coal are coming from both European and South American ports usually supplied with Welsh coal, and already sales have been made and shipments moved. It is difficult to ascertain at what prices the export coal is being sold, but it is not believed quotations have been over $2.85, though perhaps some may have been made at $2.90.

There is a little above the normal supply of coal at Tidewater, with a fair amount coming forward from the mines, and, unless the demand should greatly increase, there is no prospect of a shortage during the next few weeks.

Export shipments during the week have been made to St. Lucia, Port Antonio, Port of Spain, Havana, Kingston, Rio de Janeiro, Santos, Stockholm, Las Palmas, Aalesund and Toulon. Stockholm, Aalesund, Las Palmas and Toulon buy almost all of their coal from the Welsh market; Rio de Janeiro and Santos also buy Welsh coal, but Atlantic coast ports supply some coal to these and other Brazilian ports. It is said that the coal sent to Stockholm was the first cargo of coal to be shipped from Hampton Roads to that port, and that its sale was due to inability of buyers to get a supply from Wales.

COAL CHARTERS

The demand for tonnage to carry coal to South America and Mediterranean countries continues active and rates have eased up. A charter made early this week for coal carriage, September loading, from Virginia to Rio Janeiro was closed at $5.40 against $6 being paid for the same voyage last week. Quite a few boats have been fixed to carry coal to Las Palmas and Italian ports and chartering agents report that they expect the demand for tonnage in this trade to continue for some time after the conclusion of the war in view of the fact that the English Admiralty has commandeered most of the coal stored by the Welsh operators, and that mining operations have been seriously hampered by the calling to arms of miners. American coal operators state that New River, Pocahontas and other high-grade coals have been sold in large quantities for early shipments. Spain, Portugal and Egypt have sent in large buying orders as well as Italy and South American countries.

It is stated that freight and insurance rates on coal vessels had eased up considerably, but that the English moratorium was to some extent holding up the final consummation of many contracts. It is the general practice to make all bills for coal shipped to foreign ports payable in London and for this reason operators are insisting that shippers have bills payable in New York on the surrender of the proper documents. To a certain extent where coal is urgently needed this has been done, but the recent improvement in the foreign exchange situation and the general attitude taken that exchange will shortly assume a normal aspect lends color to the statement that large sales of coal to Europe and South America will soon start under the usual terms of sale with bills payable in London.—"Journal of Commerce."

Coal charters have been reported as follows:

Vessel	Nationality	From	To	Tons	Rate
Navisbrook[2]	British	Atlantic Range	Bahia	1965	$6.00

LAKE MARKETS

LAKE TRADE

The business has had its ups and downs in past years, but it has never before received such a variegated assortment of rebuffs as this season. It opened lamely enough, but hope burned brightly. Everybody believed that things would get better in about a month and vessel owners did not lose hope, but merely postponed their expectations, arguing that the furnacemen could not stay out of the market forever.

But now comes a staggering conflict of armed forces abroad and the export trade goes glimmering. Vessel charters are cancelled; grain is loaded into vessels and then unloaded at the loading port; other vessels leave and are recalled, and still others that deliver their cargoes cannot get their freight money. Meanwhile the elevators fill up and there is stagnation and delay all around. Time is being eaten up and the ships are not earning anything, and altogether a state of demoralization prevails, of which no one can see the end. Vessels are going to dock by scores, because there is nothing for them to do. The year 1914 will be long remembered on the Lakes as the worst on record.—"The Marine Review."

PITTSBURGH

Mining continues at about 70% of capacity. Manufacturing demand slightly better. Circular prices still purely nominal, but slack a shade firmer.

The local coal situation has shown very little change for

several weeks, but such as has occurred has been in the direction of improvement. The demand from manufacturers is, on the whole, measurably heavier than two or three weeks ago, due partly to the practical exhaustion of the last of the stocks laid in against the expected suspension last April, and in part to slightly heavier operations at mills and factories. The steel trade is running at a slightly better rate than in July, an increase in shipments to domestic consumers having more than made up for the sharp decrease in exports caused by the war.

Shipments in the Lake trade have improved slightly, but they are not at as great a rate as was expected would be the case a month ago. Production of coal in the Pittsburgh district is at approximately 70% of capacity, on an average, but some mines are operating almost full and others are running at less than 50%.

Prices continue to be very irregular, slack suffering a greater discount from list than any other description, although it is slightly firmer than a fortnight ago, at 55@60c. for steam-coal slack and 65@70c. for gas-coal slack. Mine-run can be had on desirable contracts at $1.15, while spot lots can sometimes be had at close to a dollar a ton. Regular circular prices, which are purely nominal, remain as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.50, per ton at mine, Pittsburgh district.

BUFFALO

Canadian roads stocking heavily in anticipation of treaty complications cutting off the supply. Other lines slowing down and requirements light. Unusually large amount of early buying in anthracite.

Bituminous—The demand is still below normal, owing to the European war. Canadian factories in numerous instances are doing little, and there is not much prospect of immediate resumption of business there, as everyone is taking a great interest in the war, and many lines of trade are upset. Sellers are looking closely after collections, which as a whole are said to be poorer than usual in the Dominion.

The heaviest buyers in Canada today are the railroads, and they are stocking up more freely than usual. The movement across the International Bridge has lately been above normal, the bulk of the coal being for railroad use. The stories that much of this coal is intended for use of the British Navy has been authoritatively denied. The railroads are simply getting prepared for any possible shortage this fall.

Offerings at low prices are somewhat less common than they were a short time ago. The market could easily become congested at present, if consignment shipments were sent in to any extent. Prices are on the basis of $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.15 for slack. There is not much call for slack just now. Allegheny Valley coal is selling at about 25c. below the Pittsburgh.

Anthracite—Early buying has been the feature of the anthracite market this season. A large part of the business that would ordinarily not be placed until weeks later has already been covered, so that September will find a great many retailers carrying heavy supplies. This is true especially of Canada, where there has been alarm over the supply on account of the war abroad. There will undoubtedly be a reaction sooner or later to make up for the almost unprecedented amount of early ordering this month, but August trade will be considerably above the average.

The Lake shipment of anthracite is slightly less than early in the summer. But the docks at the Upper Lake ports are said to be well supplied and there is not much prospect of any shortage this winter. The start of the grain movement this fall will bring a good many boats here looking for return cargoes, and a larger amount of coal will be shipped. The shipments of the past week amounted to 97,500 tons.

TOLEDO

Lake shipping greatly improved. Domestic grades gaining strength. Slack touches the lowest point in years. Railroads buying from hand-to-mouth.

There is a noticeable improvement in the demand for domestic coal, and prices are improving; in fact, it is predicted that there will be a substantial advance in prices by Sept. 1. On the other hand, nut, pea and slack are extremely hard to move and have reached the lowest ebb known in years. The Lake movement is heavier than it has been for months past, and boats are being loaded and cleared with great rapidity. Considerable coal is being shipped to Canada. Shippers and buyers are anticipating complications in connection with the war, and are moving the coal while they can.

The situation at the mines remains practically unchanged. The Pittsburgh No. 8 field is no nearer a settlement. Merchants in the towns affected by the strike declare that business is absolutely paralyzed and demand that the miners take some action looking toward a settlement. Railroads are buying little, as they are hoping for a settlement of the Pittsburgh No. 8 difficulties and are holding off their yearly contracts in the hope of securing this coal. The railroad men generally consider the Pittsburgh No. 8 coal as best fitted for their purposes.

COLUMBUS

Production gradually increasing and prices are holding at fair figures. Indications of an advance in the circular after Sept. 1. Eastern Ohio is still idle. Lake movement quite large.

Activity prevails in both the domestic and Lake trade. The steam trade is still slow, but that is to be anticipated when business conditions are taken into consideration. On the whole, the tone of the market is fair and the prospects for the future are not bad.

The Domestic Trade is probably the strongest point in the market. Dealers are placing orders for immediate delivery, as the stocking season is at hand. They are in the market for domestic lump from Ohio districts as well as Pocahontas and West Virginia splints.

The Lake Trade is active and a large tonnage is being shipped to the Northwest. During the week ending Aug. 21, the Hocking Valley docks at Toledo handled 108,000 tons, as compared with 100,000 tons the previous week. A total of 1,500,000 tons has been handled by the docks since the opening of navigation. The demand for fuel from the Northwest is strong, and docks are generally in good shape.

Production in the various Ohio districts is gradually increasing, and many mines are up to the limit. Others are being placed in shape for operation, and tipples are being rebuilt as fast as possible. Eastern Ohio is still idle because of the failure to settle the wage scale.

Prices in the Ohio fields are:

	Hocking Valley	Pittsburgh	Pomeroy	Kanawha
Rescreened lump	$1.60	....	$1.75	$1.50
1¼ in.	1.50	....	1.60	1.50
¾ in.	1.30	$1.20	1.40	1.30
Nut	1.15	....	1.50	1.15
Mine-run	1.10	1.05	1.15	1.10
Nut, pea and slack	0.45	....	0.50	0.45
Coarse slack	0.35	0.35	0.40	0.35

CLEVELAND

Spot coal about equals the demand, and consignments are hardly a factor. Business is on the basis of 60 per cent. of normal. Lake shipments light, but reports indicate the movement from upper Lake docks is steadily increasing.

Prices are holding steady on all grades and the supply is as large as necessary. The market for slack shows a little more strength, which is due probably to the erratic buying that characterizes this grade. Though prices have not changed materially, the demand is stronger just now. Operators have found the Cleveland market too uncertain to warrant consignment coal, and, with one or two unimportant exceptions, have ceased to ship on speculation. The only increased demand is from Canada.

Youghiogheny and Pan Handle coals are the principal offerings, especially on slack. The Fairmount operators are sending in some coarse coal. Goshen and Cambridge are shipping a little of this grade, but only a few mines are working, because the clean-up work has not been finished.

No. 8 Operators have arranged to meet the miners in joint conference Thursday afternoon at Wheeling, W. Va. This is neutral ground, and it is thought the old arguments can be avoided and a new viewpoint brought out. This is the only hope operators have of a settlement.

Lake Shippers are having trouble getting boats of the 3000-ton class to go to Lake Superior. There is no demand for these boats in traffic that furnishes down cargoes and the owners are keeping them in the Lake Michigan trade. The shippers have so little dock space they require small boats. Shipments from Duluth-Superior docks are on the basis of 20,000 tons a day, as compared with 30,000 tons a day last year. The grain movement is light at Duluth-Superior and the railroads are taking very little coal for that reason. The country trade is said to be without much coal on hand.

Quotations are as follows:

	Pocahontas	Youghiogheny	Fairmount	No. 8 W.Va.	Massillon
Lump	$3.60				$3.20
Lump, 1¼ in.		$2.25	$2.05	$2.10	
Lump, ¾ in.		2.25	2.05	2.10	
Egg	3.60				
Mine-run	2.60	2.10@2.15	2.00	2.00	
Nut		2.20			3.20
Slack	2.35	1.60@1.65	1.70	1.55@1.60	

CINCINNATI

Steam market severely restricted by decreased industrial activity on account of the war. Domestic movement is still slow, but increases are predicted soon. Heavy rush expected in the fall.

Cancellations of European orders for machinery and other products manufactured locally have made the resumption of normal activity among industrial plants seem only a remote possibility. But, on the other hand, the energy being displayed in securing a stronger footing in South American and Asiatic markets gives promise of ultimate success. Just now, however, prospects are not good for the hoped-for strengthening of the screenings market, which has for some time hampered the movement of domestic coals.

While the local domestic market continues dull, there is every indication of an early change in this situation. The usual summer storing movement has already been delayed considerably, and when it does begin it will mean an unusually heavy volume of business in a short period. It is also the unanimous opinion of operators interested in the Virginia, West Virginia and eastern Kentucky fields that those sections will be called upon very shortly for large quantities of coal for export, and this can hardly help stimulating the market very materially.

DETROIT

Some activity in Hocking coals, which are popular in this district. Steam coals slower.

With the opening of the Hocking mines in Ohio, there has been considerable negotiation on these fuels, which are among the most popular in the local market. Hocking lump is now quoted at $1.60, f.o.b. mines, which is about the same as last year. Steam business is not so active, manufacturers withholding orders until the outlook is better defined. Prices continue low on the steam grades, slack being quoted over a wide range from 50 to 75c., with most of the business being negotiated more nearly at the lower figure.

SOUTHERN

BIRMINGHAM

Outlook favorable though adverse conditions prevail in the cotton business. Large sales of pig iron.

There has been very little change in either the lump or steam coal market this past week. While the demand is still far below the possible production, some orders are coming in, and quotations seem to have steadied up to the circular prices.

While the prospects for an increased activity are evident, still, there is some uneasiness that the usual oil mill trade will be greatly curtailed, due to the fact that the farmers are inclined to hold their cotton, without even ginning it, which would naturally shorten the oil mill season. Blacksmith coal seems to be in a satisfactory condition, both as to tonnage being moved and prices, which remain firm at $2 to $2.25 f.o.b. mines for the best grades. Furnaces report heavy sales of pig iron, the average price being about $10.25 f.o.b. Birmingham. Some furnaces are obtaining a price slightly in advance of this.

LOUISVILLE

Crop and business uncertainties making the market irregular. War adversely affecting the situation. Prices lack steadiness.

Market conditions in Kentucky are "spotty." Some companies are doing very well, while others are reporting slow sales and cut prices. The Southern market is in bad shape, due to suspensions and curtailment of operations on account of uncertainty as to how the cotton crop will be handled.

The interior market is not looking as well as was expected; crops have not been as large as anticipated, while in certain sections adverse tobacco prospects are affecting buying power and credits. However, the mines are running nearly full again, but it is generally admitted that the momentum gained before the war unsettled conditions has been lost, and that there is considerable handicap to overcome.

Nut and slack and most steam coals are weak in this section, the former being especially long on the Louisville market. For the first time, too, West Virginia coals from mines located on the Cheapeake & Ohio R.R. are being quoted in this market. Eastern Kentucky block coals are quoted at from $1.65@1.90, egg at from $1.15@1.40, while steam run-of-mine ranges from $1@1.05 and is hard to move. Nut and slack vary from 60@70 to 40@50c., with the lowest grades hard to move at any price.

COKE

CONNELLSVILLE

Market stagnant, present consumers being covered by contracts and no additional consumption in immediate prospect. Prices not quotably changed and production and shipments decreased a trifle.

The Connellsville coke market continues absolutely stagnant. There has been no increase in consumption by interests which do not make their coke, and the present consumers are fully covered. Production is regulated quite closely to requirements and no coke is being dumped on the market. There may be a little buying for September by furnaces which bought only for July and August, but as a rule present contracts are for third quarter or the entire half-year. The market is quotable as follows: Prompt furnace, $1.75; contract furnace, $1.75@1.90; prompt foundry, $2.25@2.35; contract foundry, $2.35@2.50, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Aug. 15 at 257,340 tons, a decrease of 6730 tons, and shipments at 260,490 tons, a decrease of 9478 tons.

BUFFALO

Little is being done in coke in this market, and most handlers say that their sales are only a small part of what they usually are at this time. The quotations show no change, being down to a basis where lower prices seem rather unlikely. They are on the basis of $4.25 for best 72-hr. Connellsville foundry and $3.25 for stock coke.

BIRMINGHAM

The market on both furnace and foundry coke remains unchanged from last week. There is no demand, and prices are low.

CHICAGO

A greater demand for byproduct coke in the domestic trade has been reported. This has been strong enough to confirm the new circular price of $4.85 f.o.b. Chicago. Quotations now are: Connellsville, $4.90; Wise County, $4.75; byproduct, egg, stove and nut, $4.85; gas house, $4.25.

MIDDLE WESTERN

INDIANAPOLIS

Domestic grades moving better and mines are on half-time. Operators anticipating good September movement. Falling off in requirements of railroads or factories not yet felt in coal trade.

The coal trade of Indiana preserves its usual August tenor, showing a slight improvement in the movement of domestic grades over July. There is the usual routine demand from railroads, no better buying by factories, plenty of cars available, mines operating about three days a week and a respectable demand at retail for the winter's supply. Both wholesalers and retailers expect September to bring improvement. The two unusual price advances this summer have done much to hurry up purchases.

Some mines are averaging four days a week, mostly those working the fourth vein. There seems to be a sentiment that the industrial situation is not as good as it has been, due to the war shutting off exports of factories, but if this is so, it has not yet made itself felt in the local coal trade. Coal men say a falling off in demand from factories will mean a reduction of the requirements from railroads. Operators report that the war has done nothing yet for the Indiana trade. Prices are somewhat easier, due to the keen competition. Offerings of mine-run are reported as low as $1, with screenings down to 70c.

CHICAGO

Larger sales are being made in almost every grade of coal. Supply of Hocking coal unequal to demand. Price of Springfield lump advanced 10c. a ton.

Increased activity in almost every grade of coal has been noted in Chicago during the past week. The betterment is attributed to the fact that manufacturers are concentrating their attention on home business. Market observers point out that our internal business is bound to be good regardless of the interruption to export trade due to the European war.

The lowest price quoted for Pocahontas and New River coal, even on off-grades, is $1.25, and a number of the larger producers find it easy to obtain $1.40. The chief reason for

this is the buying of supplies for apartment houses. Demands for Hocking coal are in excess of the supply. An improvement has also been noted in the splint-coal situation. It is reported that operators in the Kanawha district have sold a large amount of this coal for export. Dealers report an unusually good demand for Carterville lump and egg, and No. 1 washed. The demand for Springfield lump coal is increasing and operators have advanced the price to $1.35, making a rise of 10c. a ton. The sales of Indiana coals has been substantially increased.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.07	$2.45@2.65	$2.17@2.27	
Steam lump	1.87@1.92		1.97	
Egg		2.45@2.65		$4.05
Mine run	1.87	2.15@2.25	1.87	3.30@3.45
Screenings	1.47@1.52	1.65@1.70	1.47@1.52	

Quotations for Harrisburg coal are: Domestic lump and egg, $2.40@2.55; steam lump, $2.25; mine-run, $2.15@2.25; screenings, $1.65@1.70; No. 1 nut, $2.25; No. 2 nut, $2.40.

Carterville prices are: Lump and egg, $2.40@2.55; No. 1 washed, $2.55@2.70; No. 2 washed, $2.35@2.40.

ST. LOUIS

General trade better, although the Standard market is completely demoralized.

The market still continues to improve on high-grade coals for the domestic sizes, while prices are gradually dropping on the steam grades. The Standard market, however, has not improved at all, and, if anything, it is getting worse. Standard 2-in. lump has sold as low as 85 and 90c., while screenings are going at from 40 to 50c. In the middle of summer, the lump sold for 75 to 80c., and screenings from 70 to 80c. This averaged 75c. mine-run, but it is an easy matter to figure out what the result is when 70% of the output is sold as lump at 85c. and 30% as screenings at 40c.

In the Mt. Olive, Staunton and Sparta Fields, fairly good prices are being maintained, and a tonnage satisfactory to the operators.

The past week saw the clearing away of all the cheap Carterville and Franklin County lump coal, and the cheapest Carterville lump now on the market is quoted at from $1.35 to $1.40 and $1.45. The higher grade coals from the Franklin and Williamson County fields are going at from $1.50 to $1.75, and the demand exceeds the supply.

The Washed Coal Market is improving as far as Nos. 1 and 2 are concerned, but the other sizes are still weak. Anthracite from the Pennsylvania field still continues to move in, in fairly good tonnage, and there seems to be an increased call for Arkansas this year to take the place of unsatisfactory West Virginia smokeless.

In a general way, the future of the local market is exceedingly good, as far as the high-grade operators are concerned, but little encouragement is offered to operators in the Standard field in the way of either business or profits.

	Williamson and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	.....	....	.....	$0.85@0.95	$1.10
3-in. lump	.....	....	$1.30	....	.....

KANSAS CITY

Trade shows improvement with a distinct indication of the fall opening. Prices are steady.

There is a marked inclination to hold off on winter coal purchases, in anticipation of a repetition of last year's conditions when warm weather in November caused a decline. Farm demand is lighter, because of temporary check to threshing, many preferring to postpone this rather than pile wheat on the ground, since bins and all available storage is filled because of congested movement. Prospect of lower prices, due to war, is a factor in the situation.

The more favorable situation of the Kansas Natural Gas Co., that will enable it to supply abundant gas, has not influenced many householders yet. Local trade was slow early in August, but has improved greatly, and the fall movement seems well begun. Slack coal is growing scarce because of the strike.

The market is quotable about as follows:

	Mines	Delivered
Cherokee lump	$2.00	$2.80
Cherokee nut	2.00	2.70
Mill coal	1.60	2.30
Slack	1.50	2.20

PORTLAND, ORE.

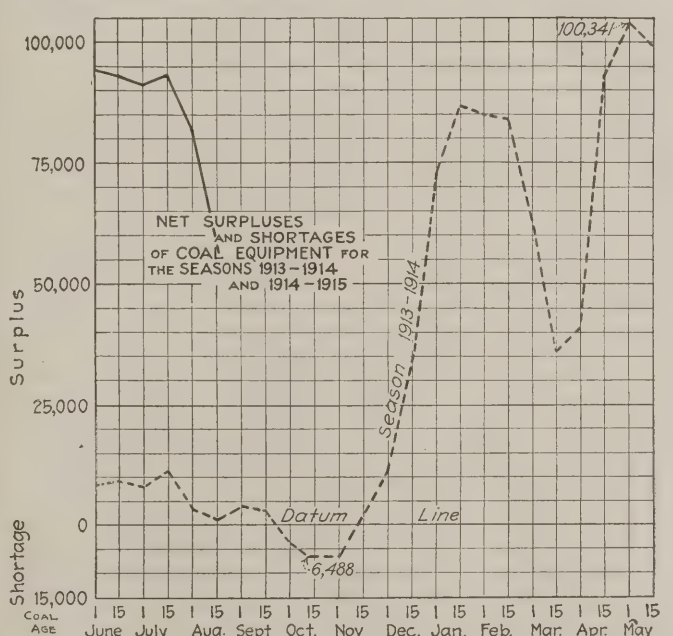
Prediction that prices will advance Sept. 1 as result of reduced importations and increased demand. Retail business active.

Coal dealers here have been busy the past few days booking orders. It is predicted that prices will advance 50c. per ton Sept. 1 on Wyoming and Utah coals, and this will probably mean a similar advance all along the line. Because of the slow movement during the summer months, dealers have not been storing up heavily, and as the mines advanced quotations Aug. 1, the wholesalers here contend that they will be compelled to follow suit.

Coal from the Centralia district is now being laid down here at a cost that permits its being retailed at $6 per ton

From the Coos Bay country comes the report that efforts will be made to ship coal here in larger quantities than in years past. The railroad into Coos Bay is not yet connected up but will probably be completed during the winter. In the meantime coal will be shipped here by boat, the service having been increased considerable since last winter. At that time the Coos Bay coal sold at $8 per ton, delivered in ton lots.

PRODUCTION AND TRANSPORTATION STATISTICS



THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Aug. 15, as follows:

	Surplus	Shortage	Net*

FOREIGN MARKETS

GERMANY

Production, imports, exports and consumption of the German Empire during the first six months of this year and last year were as follows, in thousands of tons:

	Coal	Lignite	Coke	Briquettes
Production—				
1913	93,778	15,944	41,900	13,183
1914	94,148	15,974	44,351	14,515
Imports—				
1913	5,028	253	3,503	72
1914	4,776	295	3,184	79
Exports—				
1913	16,372	3,431	30	1,638
1914	18,170	2,630	31	1,622
Consumption—				
1913	82,234	12,786	45,373	11,617
1914	80,754	13,639	47,504	12,972

The Rhenish-Westphalian Coal Syndicate has reported fuel exports for the past six years as follows:

Year	Coal	Coke	Briquettes	Total
1908	9,018,220	2,745,801	726,372	13,206,744
1909	10,766,034	2,909,084	802,626	15,234,046
1910	11,925,573	3,493,472	1,210,013	17,517,673
1911	13,087,977	3,677,478	1,578,519	19,254,930
1912	14,004,439	4,519,631	1,685,763	21,349,738
1913	15,602,770	4,401,433	1,642,792	22,757,003

GREAT BRITAIN

The London coal trade has been very erratic during the past week. In some cases prices have been reduced and in others slightly advanced. The difficulty in obtaining fuel has been relaxed somewhat, but there is still the grave danger as to what it may mean in the near future. With the return to work after the holidays, serious problems have made themselves felt in a variety of ways. So many horses and vans have been commandeered by the Government that it is becoming a very serious matter as to how the coal on order can be delivered. This difficulty seems likely to extend to the colliery end also, for it is currently reported that many of the Midland collieries have had to bring up the pit ponies in order that the Government may examine and report on the number available in an emergency. At the same time the calling up of the Territorials and Reservists has thinned the ranks of the regular workers very considerably, both in the offices and at the depots.

A considerable quantity of South Yorkshire and other qualities of steam coal and house coal usually sent to the coast for shipment have found their way to the London markets, and kept the supply well up to the demand. There is no denying the fact that the general public during the first few days of the outbreak of the war completely lost their heads and rushed in orders far beyond their actual requirements. Business has been very irregular in London during the whole of the week, and there are still many collieries who are declining to enter any orders whatever, except for contract coals. All colliery quotations are still withdrawn, so that buying is limited to very small proportions until the position of affairs is better known.

One of the first features of the effects of the war is the shortage of pit props and oil, and it is feared by some that this will considerably lessen the output unless the local supplies can be made serviceable. In the seaborne market no Durham or Yorkshire qualities are offering. Vessels are, however, still running along the coast, and on Monday, 15 contract boats were reported as entering the Thames, and on Wednesday 9, all sold. Manufacturing fuels, whether of the large coal or the nutty slack varieties, were in good demand, and fetched good prices. The lowest summer prices are still the prices in operation for the public delivery. In some cases, however, the advertisements have been withdrawn, as so many orders have been received over and above the normal requirements.—"The Colliery Guardian."

BRITISH EXPORTS

British exports for July of the past three years were as follows:

To	1912	1913	1914
Russia	648,018	880,066	870,385
Sweden	472,276	402,713	423,349

FRANCE

So far the war is having no direct effect upon French coal markets, except that, of course, the demand has fallen off greatly, owing to the shutting down of the big iron works of the North and East, as well as many factories throughout the country. At the same time, however, the authorities have extended the mobilization orders for miners to 45 days, so that the personnel of the collieries has not been diminished to any great extent. This assures the supply of the national requirements, more particularly the railways, the armament constructors, and the shipbuilding yards, all of which are working at high pressure. There are also quite a few demands for a new business to take the place of the German and Belgian imports now stopped, but the prices are being kept at their previous level. Transport at present is a problem, for the railway facilities are enormously reduced, and even water carriage is interfered with through lack of men to man not only the barges, but the discharging plant. However, the Northern collieries are loading up as many as they can obtain, and despatching them to Paris and the South. The question of pit props is being settled by the same means; many of the big barges which come to Paris with wine are now going through laden with timber. Towage is a further problem, and is handicapping this traffic, for the big barges can only move with tug boats, although the smaller coal barges from the North can move with horse towage.

The household trade in Paris is pretty much at a standstill through lack of local delivery wagons; consequently, middlemen are enabled to ask very much enhanced prices, not justified by the colliery prices, but simply on account of their own personal difficulties. At the moment all price lists are cancelled, and prices may be anything. American exporters are making a bid for Government business here just now, but so far without much success.

The Americans will hardly do much business yet, because in the first place they do not seem prepared to quote on a c.i.f. basis, and local dealers have no means at present of chartering. Today there was a quotation from America for New River at $3 a ton, f.o.b. Newport, which would work out at a price quite unacceptable under present conditions here. —"The Colliery Guardian."

COAL AGE

Vol. 6 NEW YORK, SEPTEMBER 5, 1914 No. 10

Our Opportunity

By Berton Braley

Written expressly for Coal Age

While the hosts at Armageddon know the awful blight of war
While the rifle bullets whistle and the cannon crash and roar,
We can look with bitter sorrow at the horror of it all
But we need not weep and mutter with our faces to the wall,
We are free of all the conflict which a war-mad monarch made,
And the world is ours to conquer with the mighty force of trade,
While the other powers struggle, with a continent at stake,
All their vast and eager markets are for us to win and take.

Now's the time for trade expansion, with prosperity the goal,
South America is calling for its huge supply of coal,
And a hundred other markets scattered round the surging sea
Look to us for prompt assistance—this is Opportunity!
Let us turn again to mining, cease to mourn in sodden woe,
For the war cloud has a lining with a richly golden glow,
While our rivals burn and slaughter, while their wealth and strength decrease,
WE can conquer distant borders with the glorious hosts of peace.

If we haven't ships, we'll buy them, if we cannot buy, we'll build,
Till the face of all the oceans with our merchant fleets is filled,
Till the flag that rode triumphant in the clipper days of old
Shall be fluttering at mastheads of our vessels manifold,
And the good black coal of commerce, wrested from the hill and plain,
Shall be sent in bulging cargoes forth upon the rolling main,
While the powers clash in conflict, while the shot and shell are hurled,
WE shall gain stupendous treasure from the markets of the world.

The United States and the World's Coal Markets

The annual production of coal in the entire world is approximately 1,350,000,000 short tons. The United States produces 575,000,000, or more than 42 per cent. Great Britain produces about 305,000,000, or 22 per cent., while Germany produces 265,000,000, or 19 per cent. Other countries in their order of production are Austria-Hungary, 50,000,000; France, 45,000,000; Russia, 28,000,000; Belgium, 25,000,000 and Japan, 19,000,000 short tons. It is true, therefore, that of eight countries producing 97 per cent. of the world's coal output, the only one not now engaged in war is the United States.

Great Britain is still producing a large tonnage, and is endeavoring to maintain her place as the world's most important exporter of fuel. Her foreign business in coal amounts to approximately 110,000,000 tons annually, leaving 195,000,000 tons for domestic use. There is no doubt but that production in Great Britain will be curtailed, but it is likewise certain that her domestic consumption will materially lessen, so that considerable coal will still be available for export. She has ships, and commands the seas, so that she must be regarded still as a most formidable competitor for the export business. The chief condition against her is the recent order prohibiting the export of her best Welsh grades. We doubt if importers will be satisfied with an inferior English coal.

In Germany, Austria-Hungary, France and Belgium, the coal industry is completely demoralized, only enough colliers being left in the mines to supply fuel for the railways, armament mills, and the more important national requirements. Japan can hardly supply enough coal for her own uses, so it is evident the United States and Great Britain must furnish the world's fuel while the present war continues.

The average consumption of coal in the principal countries of the world (excluding tropical countries) is approximately 4 tons per head of population. In the United States the consumption is greater than anywhere else, being 5.5 tons per inhabitant.

Four million men are employed in mining the world's coal, of which number 1,100,000 are British, 850,000 Americans, 710,000 Germans and 200,000 are French.

South America alone needs $70,000,000 worth of coal annually, of which amount at present the United States furnishes $5,000,000 and Great Britain, $55,000,000.

If the present time is not *the* supreme opportunity to make the United States the chief fuel exporting nation of the world, then surely the chance will never come.

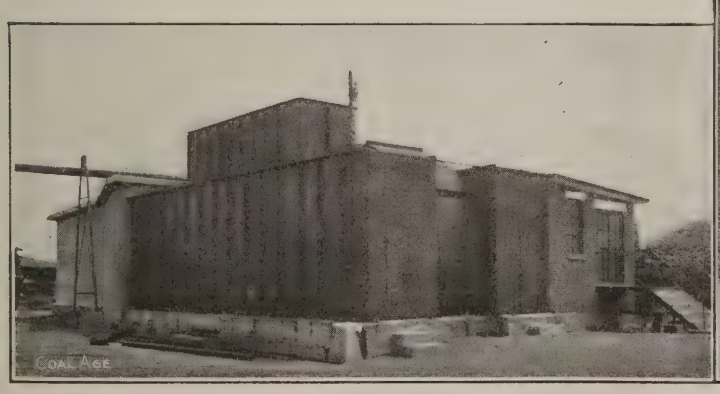
Shaft Ventilation at Butler Colliery

SYNOPSIS—A 6x14-ft. fan direct connected to a steam engine, operating at 130 r.p.m. delivers 215,000 cu.ft. against a 2.8-in. water gage. The machine is operated continuously at this rate.

Of the many mine-ventilating installations in the anthracite and bituminous fields of the United States, one of the most interesting is that of the Hillside Coal & Iron Co., at the Thomas shaft of the Butler colliery at Pittston, Penn.

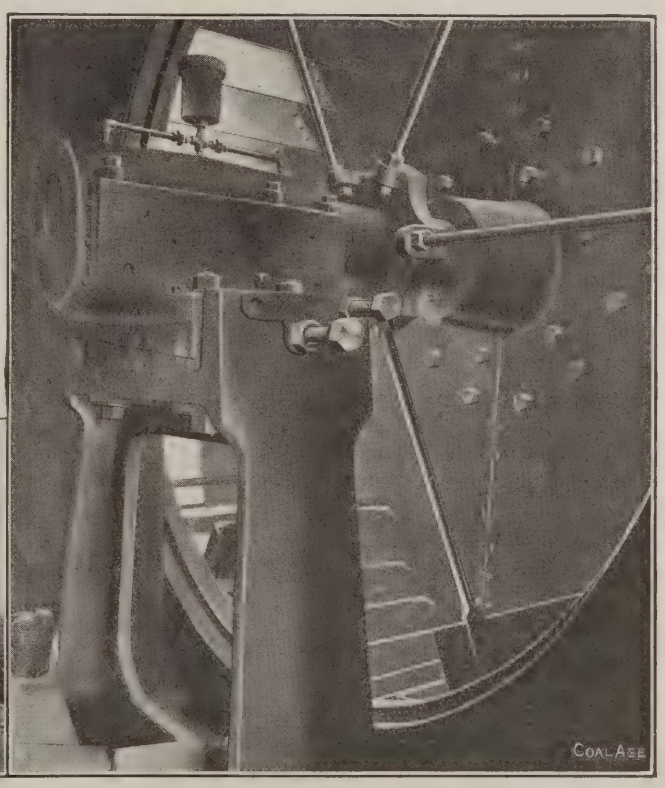
A General View of the Top Works, Showing Fan House

Interest centers in this installation because of its high-efficiency as regards volumetric output and its exceedingly simple, but staunch, construction.



The fan—14 ft. in diameter, with a 6-ft. face—is of the double-inlet, exhaust, multivane type, with three-quarters steel casing and steel airways extending out to the concrete air shaft. For accessibility, the casing is provided with air locks through which the attendants can pass to oil and care for the machinery.

The main shaft, of 0.40 carbon steel, is 11 in. in diameter, and extends through the airways on one side to the direct-connected steam engine. The cast-steel fan hub, which is 30 in. long, is pressed on and keyed to the shaft. A center steel-plate disk is secured to the hub by fitted bolts in reamed holes. There are two steel-plate rings on either side of this center disk. The curved vanes are riveted to these rings.



Heavy steel rods are riveted to the outside rings and extend to the shaft, where they are held in the cast-steel spider shown in one of the illustrations. The spider, which is keyed to the shaft, is an important factor in the maintenance of face alignment, in that it supports the adjusting nuts with which the steel rods are fitted.

The fan wheel is supported on its foundations by two heavy cast-iron pedestals. The tops of these pedestals are machined to form bearing surfaces for the adjusting wedges on which the journals rest. These are for vertical adjustment. Longitudinal adjustments are made by heavy setscrews. The main bearings are of the chain-oiling type, with an outer water jacket; this permits the connection of a water system for rapid circulation and cooling, when necessary. The bearings are liberal in their proportions and have large oil cellars.

The rigid steel construction of the fan wheel and the accurate balance that such a construction permits, has a definite engineering advantage beyond that of great strength with comparatively little weight, in that it allows a high peripheral speed, which results in large volumes of air at high water-gage readings.

Near View of Fan House and Casing

View Inside the Fan Casing, Showing Structure of Wheel and Pedestal Bearing

This fan is running continuously—24 hr. per day—and is delivering 215,000 cu.ft. of air per minute at 130 r.p.m., with a water-gage reading of 2.8 in.; at 190 r.p.m., the air delivery is increased to 315,000 cu.ft. and the water-gage rises to 6.2 in.

There is no question but what service of this nature is arduous in the extreme, since the fan has no opportunity for rest and it is strictly "up to" the design and workmanship, as well as the material, to keep the fan in service. This machine was designed and built by the Vulcan Iron Works, of Wilkes-Barre, Penn.

Butler colliery is known as one of the most modern in the anthracite field and is thoroughly equipped for handling its monthly production of 65,000 tons. It is within the system of the Pennsylvania Coal Co. and comes under the jurisdiction of W. P. Jennings, district superintendent at Scranton, Penn.

Double-Entry System in Arkansas

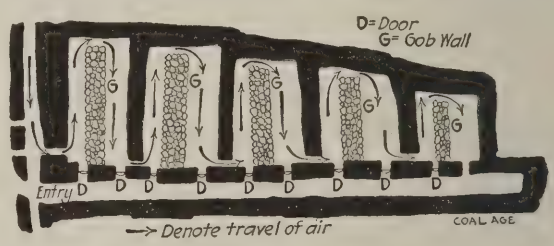
Special Correspondence

SYNOPSIS—The single-entry system dies slowly in Arkansas, both miners and operators desiring in some cases to keep it in operation. The inspector is trying to get the courts to stop mines which are being worked without double entries.

On Oct. 10, 1913, Thomas H. Shaw, the state inspector of mines, served notice on the Southern Anthracite Coal Mining Co., of Russellville, Pope County, Ark., to install the double-entry system as required by Section 7, Act No. 225, passed in 1905. The section reads:

> The owner, agent, lessee or operator of any coal mine in this state, if said mine is worked on the room-and-pillar plan, shall cause such work to be prosecuted in such mine in the following manner, to-wit: Two entries parallel with each other must be driven for the ingress and egress of the air, and crosscuts must be made at intervals not to exceed 40 ft. apart. Where gas exists, they shall be driven 30 ft. apart, or a crosscut be made at any other place ordered by the management to do so. No room shall be turned inside the last course cut*

The Southern Anthracite Coal Mining Co. drives only one entry instead of two. It opens from this double-necked rooms, which are 40 ft. wide. When the necks are in 12 ft. they are widened squarely toward each other till they meet, and as the rooms are driven up, a dirt wall is erected between the two-room roadways. Crosscuts are driven between the rooms 12 ft. from the entry.



Doors were placed on the mouth of each roadway and the air is thus driven up one road and down the other, and so long as the doors are closed and tight, the ventilation is uninterrupted. But as soon as any doors are opened, all the air beyond becomes stagnant. In such cases, it is always found that at least one door is standing open. Seeing that only 100 cu.ft. of air per minute is required by law per man employed, it is easy to see that if this is provided when the doors were all duly closed, the current will be only barely sufficient to do the work. With doors frequently opened, the air must become extremely foul.

Another trouble arises from the fact that, as the air courses up to the face of every room, when a heavy shot of coal is made, it fills up the space between the rib and the gob wall, and largely prevents the air from circulating.

Was the Law Violated?

Lee McDowell, the superintendent, declared that the system was in accord with the law and suggested that perhaps the breaking of the continuity of the air current by gob pillars in the counter airway composed of crosscuts and rooms, was the only manner in which the law was violated. So he proposed to cut the gob pillars and let the air circulate in a straight line through the initial crosscuts. The inspector insisted that this would only make conditions worse, as the air would then not circulate to the faces of the rooms.

Finally, the superintendent agreed to make a double entry, such as was doubtless contemplated by the framers of the bill, providing that the Ideal Anthracite Coal Mining Co. mining nearby was compelled to operate in a similar manner. W. H. Barrett, the general manager of the company, promised to do so and has kept his engagement, and Mr. McDowell agreed to do the same, but in April, 1914, he was still using the same system.

How Some Arkansas Mines Are Still Operated

The Miners Side with the Company

Five men elected by the local union of the United Mine Workers of America tried to get the inspector to meet them in the hope that they might persuade him to withdraw his objection to the method of working as they claimed it would reduce their wages if the work was done on the double-entry system. It is difficult to see how that could be. The inspector refused to meet the men, as the requirements of the law were not rightly, in his belief, a matter for compromise.

Little Law and Not Much Provision for Enforcement

On Apr. 29, 1914, the inspector applied in the Circuit Court for an injunction to close the mine, alleging that it was dangerous for the workmen, owing to the foul air and the lack of ventilation to remove standing gas. Judge Basham ruled that he could not grant an injunction, as he was without jurisdiction, and he dismissed the case, so on May 9, 1914, the inspector sought to enjoin the Southern Anthracite Coal Mining Co. in the Pope County Chancery Court, to cease the operation of their mine, alleging dangerous conditions and open violation of the law. He also served notice on the prosecuting attorney, requiring him to prosecute the company for not ventilating the mine and for driving single headings in open violation of the law. The injunction was brought under Sec. 5349.

Chancellor Sellers ruled that the Act 225 of 1905,

*We suppose "ordered by the management to do so," means "when the management is ordered so to do by the mine inspector." "Course cut" is evidently an error and should be "crosscut."

amending the mining laws by implication, repealed the act granting the courts power to serve an injunction by which any company could be required to close its mine. He stated that the only remedy at law was to have the prosecuting attorney proceed against the company as a misdemeanant. In this case the company would possibly pay the fine and not discontinue its practice.

So the inspector has appealed to the Supreme Court to reverse the decision of the chancellor. If this court decides in favor of the chancellor's decision, the law rests entirely with the prosecuting attorney in this and other provisions and so far he has not shown any disposition to act in a case of this kind.

The Miners Want the Inspector to Acquiesce

When the suit was commenced, the men supported the company. Thomas King, one of the organizers of the United Mine Workers of America, went to Russellville and "roasted" the men so severely that they changed their stand and quit work. After the decision, P. R. Stewart, district president of the Union, wired the inspector to meet him at Fort Smith, as Mr. McDowell was clamoring for the men to return to work. The inspector refused to modify his stand and the Union officials, being afraid to order the men to return to work in what was declared to be an unsafe mine, left it open to the men to do as they pleased and they have returned to work.

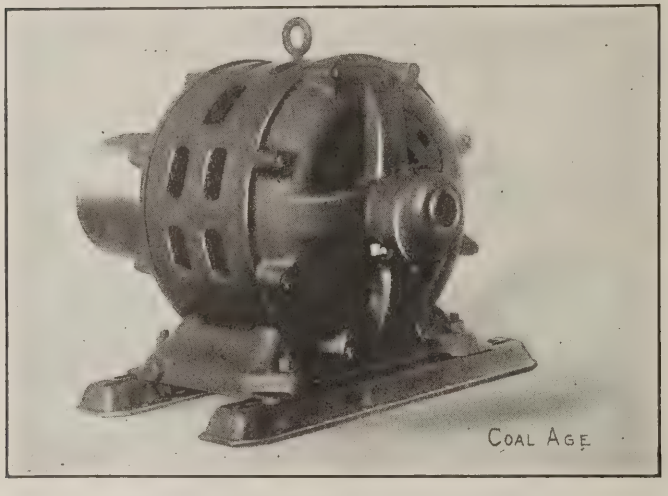
A few of the larger companies have shown a disposition to comply with the law, but the rest are unwilling to do so, inadequate as it is in many of its details.

Belgian Coal Exports

Coal is the greatest by far in quantity of any article exported from Belgium, and is sent for the most part to France, which received 4,340,500 tons in 1911. Germany received 293,000 tons, and the Netherlands 266,000 tons, the remainder being in small quantities, the chief of which is 113,000 tons to Luxemburg. As a Consular Report (British) indicates, the total figure is largely composed of bunker coal placed on board vessels bound to the countries to which it is credited as exports in the statistical returns. The exports of Belgian coal during the years 1902-11 were:

Year	Quantity in Tons	Year	Quantity in Tons
1902	5,073,000	1907	4,732,000
1903	4,923,000	1908	4,754,000
1904	5,067,000	1909	5,077,000
1905	4,705,000	1910	4,973,000
1906	4,972,000	1911	5,169,000

The least objectionable feature of boiler soot is that it is unburned fuel. The worst features are its ability to screen the boiler tubes from the heat, the quantity of sulphur in it which corrodes the tubes, and its interference with draft so that a greater pressure has to be put on the fire.



The Miner—Guess I'll Stick and Play Safe

A Two-Speed Alternating-Current Motor for Mine Ventilation

By William H. Easton*

SYNOPSIS—It is often advantageous to vary the speed of mine fans. With direct current this is easily accomplished. Where alternating current must be employed, a slip-ring motor gives the required speed variation, but is subject to some serious shortcomings. The two-speed induction motor is perhaps on the whole the machine best adapted to fan driving when constant speed is undesirable.

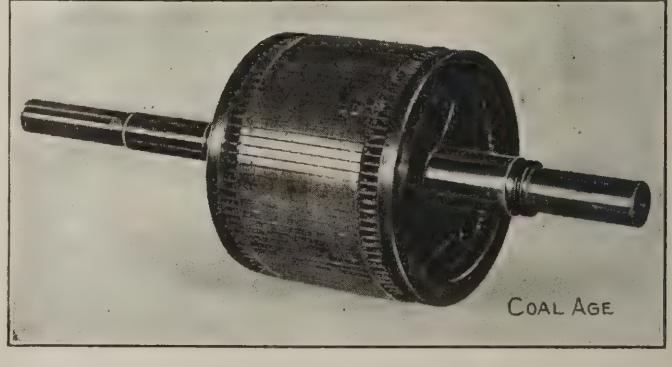
It is frequently desirable to alter the speed of motors driving mine fans. Less air is required at nights and on holidays than while work is in progress, and a reduction in the speed of the fan at such times effects

The Two-Speed Motor Complete

a decided economy. Again, an increased volume of air is demanded from the fan as extensions below ground are made, and this extra supply is most easily obtained, up to a certain limit, by increasing the normal speed of the fan.

When a direct-current motor is used for fan driving, no difficulty arises as to speed changes. The speed of a direct-current motor can be readily varied over a wide range in any desired number of steps.

But the increasing use of alternating current from central stations and the many desirable features of the motors using this energy supply—such as reliability, simplicity and ability to utilize current of a high voltage—have developed a demand for a suitable alternating-current motor for fan drive, one of the characteristics of which should be speed variation.



This demand has created a serious problem for the motor manufacturers to consider, because the alternating-current motor does not lend itself readily to speed variation. The ordinary squirrel-cage motor, for example, well suited to mine service in many respects, is essentially a constant-speed machine, and no method of changing its rotational velocity is now considered practicable.

With the slip-ring (or wound-rotor) motor, speed variation can be obtained by introducing resistance into the rotor circuit. For this purpose, a drum controller is employed and resistance connected into the rotor circuit through the slip rings. For services where the operation is intermittent and the motor runs on low speeds but a short total time each day, as in hoist, crane and elevator service, this type of machine is eminently satisfactory. But where operation on low speeds for long periods of time is necessary, the slip-ring motor becomes uneconomical because much energy is wasted in the resistance.

Thus a 20-hp. slip-ring motor has an efficiency of 87 per cent. when driving a fan at full speed. But when operating the same fan at half speed, its efficiency (including losses in the resistance) drops to 37 per cent., which means that but little more than one-third of the total power received (and paid for) is being transformed into useful work.

When the fan must run at a slight speed reduction or at low speeds for short periods only, a slip-ring motor can be recommended. But for long operation on low speed, some more efficient substitute should be found.

One type of motor that has proved entirely satisfactory whenever it is applicable is the two-speed squirrel-cage induction motor. This has been used extensively for machine-tool and other service, and has been applied to mine-fan drives for years, although it has only recently become conspicuous in this latter field. This motor is similar in its mechanical construction to the ordinary squirrel-cage machine. It has the same simple and reliable mechanical construction throughout. It has only two wearing parts, the bearings; it has no sliding electrical contacts, and its rotor is practically indestructible. The stationary windings are arranged differently, however, although they are mechanically just as strong and

Rotor of the Two-Speed Motor

present no outward differences with the exception of the fact that a greater number of leads are brought out.

The Operation Is Simple

The method of operation of this machine is simple. The speed of any squirrel-cage motor depends on the number of its "poles." Thus, on a 60-cycle circuit, a two-pole motor has a no-load speed of about 3600 r.p.m.; a four-pole motor, 1800 r.p.m.; an eight-pole motor, 900 r.p.m., etc. It is therefore evident that by changing the num-

*Westinghouse Electric & Mfg. Co., East Pittsburgh, Penn.

ber of poles, the motor speed can be varied proportionately.

This is what is done on the two-speed motor. The windings of the stationary part are so arranged that by connecting them in one way a certain number of poles is formed; while by changing the connections, twice the number of poles is secured and the speed is reduced to one-half. The horsepower is also reduced one-half. In either condition, the motor's operation and characteristics are similar to the ordinary squirrel-cage machine having the same number of poles.

The reason why this type of motor is particularly suitable for fan service is that half speed is just the reduction that many mines require during nights and holidays. Hence its range of application is broad.

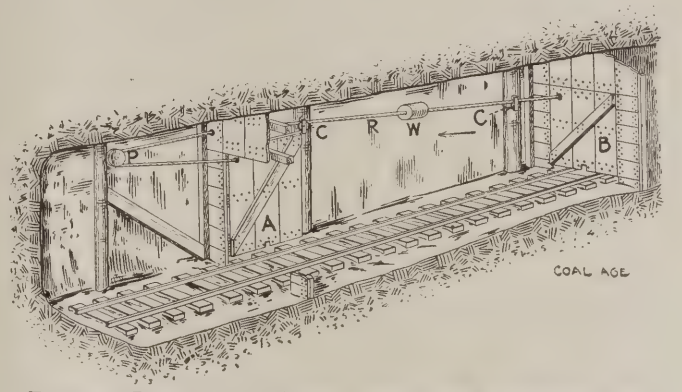
In this machine, the excellent mechanical features of the ordinary squirrel-cage motor are retained intact, as mentioned above, no commutator or other complication requiring attention being necessary.

The change in connections is effected in the simplest possible manner. A double-throw knife switch is provided, which when placed in one position, gives one speed, and in the other gives the second speed. Otherwise, it is started in the same manner and with the same appliances as the ordinary squirrel-cage motor.

The efficiency of operation on low speed is excellent, being nearly the same as that on high speed. The reduction of horsepower at low speed is of no consequence in fan driving, since the power required to operate a fan falls off rapidly as the speed is decreased.

Gradual increase in the speed of the fan to keep pace with extensions is taken care of by changing the motor and fan pulley ratios to give a higher fan speed as development work progresses.

It will be noted that the two speeds provided by this motor are as 2 to 1. This is the most practical condition for this type of machine. In this case, the entire winding of the motor can be used for both speeds; hence the machine is economical both to build and to operate. Were the ratio different, say 3 to 1, two separate windings would have to be used, one providing three times the number of poles that the other secures. Such a motor is expensive to build and its operating efficiency is not so good, although it has been used in many installations. An interesting instance is a 4 to 1 speed motor, where two two-speed windings are employed, giving no-load speeds of 1800, 900, 450 and 225 r.p.m.



The two-speed 2 to 1 motor, however, fills the demand for ventilating service so well and has so many specific advantages that it is certain to become a feature of the electrical equipment of coal mines.

The Ramsay Mine-Door Closer

The setting open of a mine door, through the thoughtlessness, carelessness or malicious intent of mine workers, is not only a source of continual annoyance to the officials in charge of the ventilation of the mine, but is a menace to the safety of the men working therein.

The purpose of a door erected in a main airway or in a crosscut between two airways, one of which is the intake and the other the return, is for the purpose of permitting the passage of men and animals and preventing the air current from short-circuiting at this point. Such doors are called "division doors" when placed in the crosscut between the main intake and return airways of a mine. At all such important points, two doors or, as we say, "double doors," are erected in the same crosscut. The purpose of the double doors is to prevent the momentary short-circuiting of the air when one of the doors is open for the passage of men or animals. One of these doors should always be closed when the other is open, so as to prevent the air current from short-circuiting at such a time.

The accompanying sketch shows a device, recently invented by Thos. Ramsay, mine foreman for the Northwestern Improvement Co., Roslyn, Wash. It consists of a rope or wire *R*, of sufficient strength, attached to and connecting two mine doors *A* and *B*, located in a crosscut between the intake and return airways. Between the doors, the rope is supported by two pulleys *CC* and, passing through a hole in the brattice at the door *A*, is carried over a tail-pulley *P* and attached to the inby or

Ramsay Device for Operating Division Doors in Mines

return side of the door *A*. As shown in the cut, a heavy weight *W* is attached to the rope between the carrying pulleys *CC*, its purpose being to take up any slack in the rope and to keep the doors closed, should either of them be opened by accident or by heavy concussion of the air. From a study of this arrangement, it is evident that only one of the doors *A* and *B* can be opened at one time, and the short-circuiting of the air when men or animals are passing through the doors is thereby prevented.

This device has been in successful use for several months in one of the mines of the Northwestern Improvement Co., at Ronald, Wash., where it was installed to test its practicability in the mine. As a result, its practical working and usefulness for the purpose, intended have attracted much attention and favorable comment.

A New Dust-Laying Fluid

British engineers have met the dust problem in a unique way. Nature's way of laying dust is to turn it into sandstone or clay by slow infiltration of colloid fluids. Man needs to do the same quicker. In the F pit of the Washington Coal Co., southeast of Newcastle-on-Tyne, there was shown on Mar. 21 a commercial scale trial of the new Belger colloid dust-laying process.

About 400 yd. of a main haulageway, along which pass 1000 tons of coal a day, had been sprayed with the Belger fluid during the previous two months. The fluid, whose main components are glue and a 40 per cent. solution of calcium chloride, is sprayed from a 100-gal. tank, devised by A. Owen Jones.

This tank can come down the shaft in the cage and

is then placed on wheels. The air used is at a pressure of about 2 atmospheres. It enters the tank by several small openings, so as to churn the fluid into foam, and a small jet of air is led into the outflow pipe to help the treacly liquid to become spray. The nozzles are of rubber, to enable solid particles to pass.

Humorists said the Belger process meant making the miners walk on flypaper, and any looker-on whose hand was accidentally sprayed found himself collecting every speck of dust which came near him for the rest of the day. But the track where the process has been used feels like a peaty path in dry weather, being slightly springy and not at all sticky.

Outside the sprayed area the track is several inches deep in fine dust. The sprayed roof and walls are sticky and look for a week or two as if whitewashed, then the gathering dust blackens them, but it does not appear that a fresh spraying will be needed for three months. The liquid is used warm, at 50 deg. C. to lessen its surface tension, but the spraying is not followed by evaporation, so no falls of roof result. Indeed, the liquid preserves rock from erosion and timber from decay, and does not, like water, encourage ankylostomiasis and other low forms of life.

The cost of using this spray in coal mines is about 50c. per yard per year.

A Pipe Flume for Mine Water

By H. M. Kanarr*

In the development of the Trout Run Mine of the Jefferson & Clearfield Coal & Iron Co., near Reynoldsville, Penn., a heading was driven to the dip to daylight, which provided drainage for almost the entire mine. The water from this heading was liberated on a branch of the stream which supplied the Eleanora Mine of the Rochester & Pittsburg Coal & Iron Co. with water for the boilers.

In order to avoid contaminating this water supply, the water from Trout Run Mine was carried past the Eleanora dam by means of a surface ditch which followed the contour of the hillside for almost its entire length of 3600 ft., except at one point where it became necessary to carry it across a ravine for a distance of about 100 ft.

This was done by means of a flume composed of 18-in. sewer pipe supported on 35-lb. mine rails, which in turn were carried by bents composed of 60-lb. rails bent so as to give a batter on the legs of 3 in. in 12 in. and embedded in concrete piers cast around the base.

Details of Construction and Advantages of the System

The longitudinal rails were bolted together with fishplates, and also fastened securely to each bent with U-bolts. A concrete entrance and discharge were provided so as to give some head to the water entering the flume, and to properly release it at the lower end. No bracing of any kind was used on the bents, but the flume was trussed longitudinally with two 1¼-in. mine-haulage ropes passing over each bent and under a 12-in. I-beam bolted to the 35-lb. rails at mid span. The ropes were secured to the concrete walls at one end by means of eyebolts embedded in the concrete, and at the other by a turnbuckle, part of which was similarly embedded, and which formed a convenient means of bringing the flume to a uniform grade.

The spans were 14 ft. center to center, but could have been longer if desired, as the flume was amply strong for longer spans. The character of the country in which it was built is shown by the accompanying photographs, one of which was taken to show the method of construction, the other showing the finished flume, looking up stream.

The advantages of this construction are that the flume contains no inflammable material and will not be endangered by forest fires. It will last considerably longer than a timber structure, and was cheaper and more quickly built. The joints of the pipe were cemented and should carry water better than timber, which would be subject to weather changes.

The Flume during Construction and after Completion

The cost of the finished structure is given by the superintendent in charge, as follows:

Labor	$162.54
Cement, 21½ bbl. at $1.40	30.10
Sand	22.95
102 lin.ft. of 18-in. sewer pipe	58.14
Total	$273.73

The completed flume was painted black and the sewer pipe red, making a pleasing contrast and a job which would add to the appearance of any plant, but which in this case must "blush unseen" to a great extent, due to its isolated location.

*Chief engineer, Rochester & Pittsburgh Coal & Iron Co., Punxsutawney, Penn.

Common Sense and Economy in Fan Ventilation

By J. C. Gaskill*

SYNOPSIS—An excessive amount of air unnecessary for the proper ventilation of a mine. Circulation under a low water gage desirable. Necessary requirements to produce a low mine gage. The need of two or more main intake and return airways shown by several illustrations in actual practice. The saving in fuel consumption shown to be important.

In the following article, I, first, want to give some facts relating to the conditions we have met in mine ventilation in respect to the distribution of the air in the mine. Most readers are to some extent familiar with mine ventilation, but it is probable that many do not understand what constitutes *good* ventilation in the mine.

First, it is not necessary for a mine to have an excessive volume of air in order to be properly ventilated; but it should have a sufficient quantity to give to each of the air splits what air is needed. Air splits are necessary in order to avoid using doors on the main-haulage roads. This quantity of air should be furnished with a reasonably low water gage. The question of what constitutes a "low water gage" will depend on the quantity of air required, the length of the airways, number of air splits and the daily output of the mine.

For example, take a mine producing, say from 400 to 500 tons of coal per day. This mine can be ventilated with a 3x12-ft. fan that will deliver from 50,000 to 55,000 cu.ft. of air per minute. It is possible to do this with one main airway, providing the distance to the first air split is not too great. It must be remembered, however, that as the cross-headings are worked out and abandoned, the distance to the first split increases; and, instead of a 1-in. water gage, there is now required a 3-in. gage to circulate the same air volume. Moreover, a larger volume of air is now required.

After due consideration, it is decided to install a high-pressure fan, which, it is believed, will give the necessary air volume. It often happens that when this installation has been made at a large expense, the result is only partially satisfactory and the blame is laid on the fan, when, as a matter of fact, the real trouble lies in the main airway, which is too small for the growing requirements of the mine. Instead of a single main airway, there should now be two airways, which would pass the same volume of air under one-fourth the water gage. The horsepower required for the circulation would likewise be reduced to one-fourth of the power required for a single airway. This refers, of course, to the horsepower consumed in the main airways only.

A Comparison of Duplicate Fans

The Consolidation Coal Co. is at present operating two fans of the same make and duplicates of each other, in every respect. In October, 1910, one of these fans was installed at Mine No. 43, that had, at that time, been in operation about 18 years. There were four main-return airways, each 7x10 ft. in section and 4000 ft. long. Up to this time, the mine had been ventilated by a Capell fan, 8 ft. wide and 11 ft. in diameter, running at a speed of 224 r.p.m. This fan was now replaced by another 6 ft. wide and 20 ft. in diameter, which delivered 202,320 cu.ft. of air per minute, under a 3.5-in. water gage, at a speed of 90 r.p.m. This yield would correspond to 100,000 cu.ft. per min., under a water gage of 0.855 in., which shows a volumetric efficiency of 119 per cent. The peripheral speed of the new fan, at 90 r.p.m., is 5654 ft. per min. To deliver the same quantity of air, under the same gage, requires a peripheral speed of 7728 ft. per min., showing an increase of 2086 ft. per min., in favor of the new fan.

The duplicate 6x20-ft. fan, to which I have referred, was installed at Mine No. 119, in 1912. This mine had then been in operation six years. It had three return airways, each 3 ft. 8 in. high by 16 ft. wide. The distance from the air shaft to the first air split was 4200 ft. on the intake; and the corresponding distance on the return was 3800 ft. At a speed of 71 r.p.m., this fan delivers only 71,000 cu.ft. per min., against a 1.9-in. water gage, which corresponds to a circulation of 100,000 cu.ft. per min., against a 3.77-in. water gage; or 200,000 cu.ft. per min., against a 15-in. water gage, which shows a volumetric efficiency of only 53 per cent.

These data afford a practical illustration of two fans that are duplicates in every respect, but operated under conditions that differ widely in regard to the mine. In both cases, the fan shaft is 10x12 ft. in section and about 60 ft. deep. While the first fan has proven all that was expected and yields a volumetric efficiency of 119 per cent., the second fan gives an efficiency of only 53 per cent. The comparison of these tests proves conclusively that the mine conditions determine very largely the efficiency of the ventilating fan.

It may be stated that both fans were built under a guarantee of 250,000 cu.ft. per min., against a 6-in. water gage. The fan installed at Mine No. 43 would deliver 250,000 cu.ft. per min., under a 5.34-in. water gage, as estimated from the yield previously mentioned; but the fan installed at Mine No. 119, estimating on a similar basis, would show a water gage of 23.56 in., for a circulation of 250,000 cu.ft. per min. The conclusion is that the dimensions of this fan are not adapted to the mine it is designed to ventilate. We are now adding two airways in this mine, which will reduce the water gage and yield conditions better adapted to the fan. It is only fair to state that this result was anticipated in the plan of the mine, which was arranged to provide for the additional airways when required.

Preparing Specifications for Mine Fans

It is a common thing for the mining engineer to be called upon to prepare specifications for a mine fan, for service at a particular mine, and to invite bids for the erection of the same. The specifications are based on a stated requirement of, say 250,000 cu.ft. of air per minute, against a 6-in. water gage. A manufacturer in

*Assistant consulting engineer, The Consolidation Coal Co., Fairmont, W. Va.

presenting his bid will often state that he can do better than what the specifications ask, often claiming that the dimensions given are too great and the fan unnecessarily large. Where the manufacturer is left to make his own estimate of the size of fan required, he will often make no inquiries in reference to the size of the mine airways or the present circulation in the mine; but will take chances in reference to these important data. In nine cases out of ten the new fan is installed at a new mine, where, owing to the short airways of ample size, it continues to do good work for a few years. In the later development of the mine, however, there is experienced a scarcity of air, and, referring to the guaranteed capacity of the fan, the superintendent orders the mine foreman to speed it up, claiming that it is not run at its full capacity. The results are still far from satisfactory, but the fault is not with the fan, which is now forced to operate under conditions for which it was not designed.

Calculation of Horsepower Required

A short familiar calculation of the pressure required to pass a given quantity of air through an airway of given dimensions, using the Fairley coefficient (k = 0.00000001), shows that a water gage of 1.9 in. is required to pass 100,000 cu.ft. of air per minute through an airway 7x10 ft. in section, for each 1000 ft. in length. Suppose the main airway in the mine is 3000 ft. long to the first point of split. The distance the main air current must traverse, including the return, is then 6000 ft., and the water gage required, for the passage of the main airways only, is 6x1.9 = 11.4 in. It is clear at once to any mining engineer or foreman that it would be impracticable to attempt to pass 100,000 cu.ft. of air through a single airway of this size for a distance of 6000 ft., including the return. By providing two airways of this size for the intake and two airways for the return, both the water gage and the power on the air would be reduced to one-fourth of the previous amount.

By this means, a main air current of 100,000 cu.ft. per min. can be conducted a distance of 3000 ft. to the first point of split and returned to the upcast, under a water gage of 2.85 in., requiring 45 hp. This is the horsepower on the air consumed in the main airway. These are the more important calculations in estimating the requirements of the mine in respect to ventilation. To these amounts, however, must be added the water gage and power consumed in the splits.

Finally, to determine the power of the engine driving the ventilating fan, it is customary to assume an efficiency of 60 per cent. For example, if the entire horsepower on the air, for the main airways and splits, is, say 60 hp., the required horsepower of the engine would be 60 ÷ 0.60 = 100 hp. A similar calculation shows that a water gage of 5.08 in. and 160 hp. on the air are required to pass 200,000 cu.ft. per min. in three airways, a distance of 6000 ft.; but, using four airways, the same air volume, circulated the same distance, will only require a water gage of 2.85 in. and 90 hp. on the air.

Saving in Fuel Consumption

Assuming a consumption of 5 lb. of coal per hp. per hr., the saving of 160 — 90 = 70 hp., by employing four instead of three main airways, would correspond to a saving in fuel of 5 × 70 = 350 lb. of coal per hour, or 1¾ tons in 10 hr., which figures are a fair approximation to fact, in actual practice. Assuming, then, a saving of 3 tons of coal per day of 24 hr. (less fuel being consumed during the night, when the mine is not working), at a cost of $1 per ton for coal at the mines, the total saving per month would be practically 3 × 30 = 90 tons or $90 per month, at the least computation.

Economy of Low-Water Gages

Experience suggests that economical ventilation requires that the water gage be kept down to at least 1 in. per 100,000 cu.ft. of air in circulation. As has often been suggested before, this can be done by properly splitting the air current in the mines. Experience leads me to suggest further, that for the circulation of from 80,000 to 100,000 cu.ft. of air per minute, two main intakes and two return airways should be provided; or three main airways for a circulation up to 150,000 cu.ft. per min.; and four main airways for a circulation up to 200,000 cu.ft. per min., the sectional area being 70 sq.ft. If this plan is followed, a great saving in coal will be found to result. It is important, in overcasting the air, to see that all air bridges on main airways are substantially built so as to prevent the leakage of air. Such overcasts and all stoppings on main airways should be built of concrete, for the same reason.

For the last ten years, it has been the policy of the Consolidation Coal Co., when opening a new mine, to make the projections on the maps of that mine, with enough intakes, returns and overcasts, to ventilate the mine under a low water gage. Where old mines were contending with a high water gage, air shafts were sunk, in order to shorten the airways and lower the water gage. At Mine No. 26, an air shaft was sunk 11,700 ft. from the mouth of the mine, and a new 6x20-ft. fan and a boiler plant installed. By installing the fan at this last location, it shortened the airway one-half, besides permitting the two return airways to be used as outlets or intakes, as required, thus providing four inlets in place of two, as before. Previous to the change, this mine had but two inlets and two returns. By moving the fan, the water gage was reduced from 3 in. for 100,000 cu.ft., to 1.36 in. for the same air volume, a splendid demonstration of the practical value of shortening airways. It will be noticed that 1.36 in. water gage is too high for a circulation of 100,000 cu.ft. of air, as, in case 200,000 cu.ft. were required, the necessary gage would be 5.44 in., which is far too high for everyday practice. It may be possible that this is the best that can be done with an old mine sometimes.

In estimating the saving of coal effected by moving this fan, the calculation is based on the difference in actual total horsepower required of each engine, which is 123 hp. for 150,000 cu.ft. of air. Five pounds of coal per hp. per hr. then means 615 lb. of coal per hr., or 14,760 lb., or, say 7.4 net tons per day of 24 hr. Coal at $1 per ton then means $7.40 per day, or $222 per month and $2664 per year. The water gage on the new fan will be 3.06 in. for 150,000 cu.ft. of air; while on the old fan, it would require a 6.75 in. water gage for the same air volume. The new mines opened by this company in the West Virginia coal field are three, namely, Nos. 63, 32 and 84.

Mine No. 63 was opened about eight years ago, and an 8x20-ft. fan was installed. The mine inspector's report states that on Oct. 17, 1912, this fan was delivering

151,510 cu.ft. of air, at 70 r.p.m., against a 1.8-in. water gage. This would equal a 0.78-in. water gage for 100,000 cu.ft. of air; or a 3.13-in. gage for 200,000 cu.ft. of air.

Mine No. 32 has been opened for three years. It has a 6x20-ft. fan, which was but recently started. The mine inspector's report of Sept. 26, 1912, states that this fan delivered 108,000 cu.ft., at 48 r.p.m., against a 0.6-in. water gage, which is equal to a 0.514-in. gage for 100,000 cu.ft. of air, or a 2.056-in. gage for 200,000 cu.ft. of air. It must be remembered that this mine is new and the airways are short.

Mine No. 84 has no large fan yet, but has four return and four inlet airways 7x10 ft.

Mine No. 43, which has been referred to before, at present shows a rising of the water gage. The mine inspector's report of Oct. 16, 1912, states that this 6x20-ft. fan is furnishing 171,424 cu.ft. of air, at 84 r.p.m., against a 3.2-in. water gage, which is equal to a 1.09-in. gage for 100,000 cu.ft. of air, or a 4.37-in. water gage for 200,000 cu.ft. of air. An air shaft is being sunk at a point 8500 ft. from the mouth of the mine to relieve this high water gage.

Installation at an Old Mine

At Mine No. 3, Frostburg, Md., the Consolidation Coal Co. had a 6x20-ft. fan installed, some three years ago. This is a very old mine, with large airways. The mine inspector's report of Oct. 13, 1912, states that the fan at this mine is delivering 120,000 cu.ft., at 68 r.p.m., against a 1.1-in. water gage, which would equal a 0.76-in. water gage for 100,000 cu.ft. of air, or a 3.04-in. water gage for 200,000 cu.ft. of air.

There are some things concerning this fan to which I wish to call attention. The blades were set in backwards, by error of the builders. The mistake was not discovered until after the fan had been completed and running for some time. When the maker of the fan came to test it, he found that they had made this error and the fan was running the wrong way. It was left to me to say whether the maker should take down the fan and rebuild it correctly or not. I had not seen the fan since its erection, and in making an examination found that a part of the housing surrounding the fanwheel would have to be taken down. This wall consisted of brick and concrete, no steel being used. I decided that, inasmuch as the fan was doing good work, I would let "well enough" alone. That was three years ago, and I believe that this is one of the best fans the company owns.

From the foregoing presentations and arguments, it will be seen that all fans will deliver air against a low water gage. Some fans have a larger volumetric efficiency than others, which is a good thing, as such fans can be run at a slower speed and make the same water gage.

Economical Policy in New Coal Fields

The Consolidation Coal Company has adopted a different method for the ventilation of its new coal field in the Elkhorn Division, Kentucky. The mines are all projected on the map of the coal field, showing the mines about as they will be, and giving the amount of coal they expect each mine to produce and the amount of air they expect to put into each mine. Then the proper number of airways are projected on the map, together with all overcasts, so as to handle this amount of air with a given water gage. The large mines from which it is intended to produce not less than 2000 tons of coal per day, are expected to require about 200,000 cu.ft. of air per minute when the mine becomes fully developed.

In these large mines, we have four return airways and four intakes, each of which will average 6½ ft. high by 10 ft. wide, making an area of 65 sq.ft. each. From the fan to the first split is generally about 1200 ft., and here two double-face headings are turned off—two to the right at about 1200 ft. and two to the left at about 1320 ft.—so the switches will not interfere, as the face headings are turned with a 112-ft. radius curve. Each of these two face headings will have about four room headings, making eight room headings for each 25,000 cu.ft. of air. The four room headings will be ventilated with one split of air, say about 12,500 cu.ft. to each four room headings, which will be about 1000 ft. long. Face headings will be turned every 2100 ft., center to center, and room headings are then to be turned both ways from the face heading.

The water gage that will be required in passing 200,000 cu.ft. of air to the first, second, third and fourth splits, there being four return airways and four intake airways, is estimated as follows: The distance to the first split of air is, say 1260 ft., an average between the two face headings where 50,000 cu.ft. of air goes to the four face headings. Using Fairley's coefficient of friction ($k = 0.00000001$), the water gage for 200,000 cu.ft. of air up to this first split will be

$$w.g. = \frac{0.00000001 \times 1260 \times 2(6.5+10) \times 200{,}000^2}{5.2\ (6.5 \times 10)^3} = 0.72\ in.$$

To the second split is a distance of 2100 ft., the air volume being 150,000 cu.ft., the water gage for this section is found in the same manner, and is 0.68 in. Likewise, to pass 100,00 cu.ft. of air to the third split, a distance of 2100 ft. again, will require a water gage of 0.30 in., and finally, to pass the remaining 50,000 cu.ft. the same distance to the last face headings will require a gage of 0.075 in. The sum of these four gages must then be doubled to provide for the return, in each case, which gives for the total water gage absorbed in the main headings $1.775 \times 2 = 3.55$ in.

It is well to estimate on a loss of at least 10 per cent. of the air, which means a loss in water gage of 19 per cent., which taken from 3.55 in. leaves only 2.87 in. water gage for 200,000 cu.ft. of air on the whole mine, to this point. The splits in the face headings show a water gage of only 0.075 in. for 2100 ft. with 12,500 cu.ft. of air.

All regulators on face headings should be placed near the main airway and must not be set beyond the first room heading, under any consideration. In reference to the percentage of water gage spoken of as being lost (19 per cent.), I have found in practice this loss reaches as high as 25 per cent., so that it is safe to call it 19 per cent., as 10 per cent. loss in air means 19 per cent. loss in gage. This is not all due to loss of air by leakage, but from air passing crosscuts and other wide places, which reduce the velocity.

At some of the mines there are three intakes and four returns, and it is about 1000 ft. to the first split. To pass 200,000 cu.ft. of air through three airways 6½x10

ft. for 1000 ft. will require 1.027 in. water gage. There are four return airways and the water gage on them will only be 0.57 in. for 1000 ft. long, making a total gage of 1.59 in., in and out.

The 2.87-in. water gage passing 200,000 cu.ft. of air will require just 90.4 hp. on the air, or a total of, say 150 hp. for the fan engine.

The mine fans in the Elkhorn field will be operated by a 150-hp. a.-c. motor, which should not have as much friction as a steam engine when working below capacity, for the reason that the motor will run at regular speed at all times; and, by having different sized pulleys for the motor, any speed needed for the mine fan can be obtained. Even should it have the same friction in fan wheel and motor, the 150-hp. motor will be large enough, until the water gage becomes higher, when a larger motor can be installed. The fan wheel will be 5x14 ft. and should give 200,000 cu.ft. of air at about 145 or 160 r.p.m. with this water gage, and the volumetric efficiency should be, at least, 180 per cent.

A boiler plant will be erected at each of the mines near the fan, for the purpose of adding steam to the air current when needed to humidify the mine air so that it will not be necessary to do any watering to dampen the coal dust in the mine.

I recall a mine at which had been installed a fan 7 ft. wide and 13½ ft. in diameter. This fan was delivering 116,000 cu.ft. of air at 112 r.p.m. and showed a water gage of 1.3 in. The fan was driven by a 125-hp. motor. It was stated that this fan was guaranteed to deliver 300,000 cu.ft. of air per minute, against a 6-in. water gage, at 300 r.p.m. At that time, the mine was new and the airways were not very long. Let us see what would have been the result if 300,000 cu.ft. of air had been desired while the airways were still short. The water gage will increase as the square of the velocity and the horsepower as the cube of the quantity of the air. For sake of illustration, I give below the water gage and horsepower for each 25,000 cu.ft. of air, increasing from 100,000 to 300,000 cu.ft. I use 100,000 cu.ft. as a base of beginning for simplicity. The fan delivers 116,000 cu.ft. of air, against a 1.3-in. water gage, which is equal to a 0.966-in. gage for 100,000 cu.ft. of air. Using the Fairley coefficient, as before ($k = 0.00000001$), we find as follows:

Cu.Ft. of Air	Total Hp.	In. of W.G.
100,000	21.5	0.966
125,000	42	1.5
150,000	72	2.17
175,000	114	2.95
200,000	171	3.86
225,000	224	4.89
250,000	336	6.04
275,000	446	7.30
300,000	575	8.69

Allowance has been made for 71 per cent. of mechanical efficiency in the calculation of horsepower.

Cross-Country Boiler Moving

By H. F. Pfening, Jr.*

In the month of April, 1914, the North East Coal Co., of Paintsville, Ky., purchased a new 150-kw., direct-current plant to be installed on Johns Creek, about 3½ miles from any railroad. Then came the problem of moving the boilers from the cars to the foundations. These boilers were 6 ft. in diameter, 18 ft. long and weighed 19,870 lb., or practically 10 tons each.

Rolling One of the Boilers into the Water and Towing It across the River

Hauling a Boiler from River to Power Plant

The first obstacle encountered was crossing and moving down the Big Sandy River for a quarter of a mile. This was accomplished by floating as may be seen in the illus-

*North East Coal Co., Paintsville, Ky.

tration. All the holes were plugged and when put into the river each boiler floated 16¼ in. out of water.

Each drum was towed to the mouth of John's Creek, by a motor boat, where it was then taken out of the water and up the bank a distance of about 100 ft. Here it was loaded onto a large wagon, which had 4-in. iron axles, 14-in. hubs and 5-in. tires.

It required 10 yoke of oxen or 20 cattle in all to convey this wagon and boiler to the power-house site, and even then blocks and lines were used in many places.

It required about 11 days to move these two boilers from the railroad cars at Auxier, Ky., to the No. 8 mine of the North East Coal Co., and cost about $500. This expense might have been reduced had there been a good road to travel over. As it was, however, a large portion of this amount was required to grade a road sufficient to carry such a load.

Extracts from a Superintendent's Diary

One of the most trying duties that falls to my lot is the constant necessity of convincing the wives of my salaried employees that they are receiving all of the consideration guaranteed by their husband's position with the company. These wives rank about as follows, taking the salaries of their husbands as the criterion: company physician, mining engineer, commissary manager, mine foreman, master mechanic, electrician, chief clerk, etc.

Between the wives of this group of salaried men and the wives of the ordinary miners there is little fellowship, and for that reason little chance for misunderstandings, but between the wives of the different salaried men there is much intimacy and a corresponding (or to be exact, a more than corresponding) amount of jealousy and envy.

If the master mechanic finds a way to improve his bathing facilities the mining engineer's wife begins to grumble. If the electrician improvises an improvement in his house-lighting arrangement, the wife of the company physician comes to see me next day. If the mine foreman selects a car of coal for his own use that happens to contain more than the average amount of lump coal, the commissary manager's wife gets in her work on the company teamster, and so it goes.

Of course, any man with half a sense of humor could enjoy these petty manifestations of sisterly love if he were privileged to observe them as a rank outsider, but I am far from enjoying such disinterestedness. I have learned through bitter experience that whenever the wife of one of my employees becomes dissatisfied with her surroundings the husband will soon be requesting his time slip.

Just now I am trying to convince Mrs. Mining Engineer that Mrs. Company Physician was granted a telephone in her house because some of our employees who live at a distance demanded it.

For once I feel confident of victory; however, if Mrs. Commissary Manager had protested first the jig would have been up because she would have been ably seconded by the wives of all of the miners living on the outskirts who read with envy of the growing possibilities of trading by telephone, as related by our near-by city dailies.

We have established a sort of voluntarily accepted "Common law," the ladies and myself, which allows me to turn down all applicants for each particular favor after one applicant has been vanquished. They seem to realize that were I compelled to give each one of them a hearing on every claim that might arise, I wouldn't have time left for looking after their husbands. Despite their willingness to quarrel with me at every opportunity, they seem to prefer a continuation of my power rather than risk a successor in my position.

Speaking frankly, my sympathies are largely with these ladies. They have no permanent homes, and the joy of fixing things about the place that they may enjoy them in future years can never be more than a longing for them. And overlooking altogether my sympathies in the matter, I realize that every improvement for their homes which they succeed in securing, in spite of my well meant opposition, becomes another anchor tending to hold their family in its place in our community, counteracting occasional tempting offers from rival camps.

Compressed-Air Locomotives at the Marihaye Coal Mines, Belgium*

At the coal mines of Marihaye it was decided to operate the subterranean haulage by means of compressed-air locomotives, and by the end of 1913 these had been installed at the Vieille-Marihaye pits.

The central air-compressing plant was erected above ground. In consists of two compressors of five stages each, belt driven by a 100-hp. electric motor. The number of revolutions is 190, and 10,500 cu.ft. of air are compressed per hour to about 3000 lb. pressure.

The air is cooled between each compressor stage, going through a separator to get rid of the oil and moisture. After leaving the compressor, it is cleaned and led into an air tank with four compartments of 16 cu.ft. each, from which pipes lead to the points where it is proposed to charge the locomotives.

The installation comprises about 13,000 ft. of 1⅛-in. (inside diameter) pipe of drawn steel, galvanized inside and out and provided with the usual high-pressure fittings. Each compressor can feed three locomotives in active service.

The locomotives carry a compressed-air tank composed of four flasks of drawn steel, about 13½ in. in diameter (inside) and 10 ft. long, arranged on the upper part of the chassis. The engine is of the triple-expansion type.

The locomotive carries two electric lights, one in front and one at the rear. Each machine can haul a train of 35 empty cars on a ½ per cent. grade at a speed of 100 ft. per minute, and return with the wagons loaded to the shaft, making the trip of 5000 ft. each way with a single charge of air. Each locomotive is about 12 ft. long, 31 in. wide, 55 in. high over all, and weighs about 10,000 lb.

One of the two compressors will take care of the haulage of 796 tons for one kilometer (3280 ft.) in eight hours with one locomotive. At present, one locomotive is at work on each of the two levels, having replaced six horses. It takes about half a minute to charge the air tanks. The use of these locomotives will soon be extended to the other pits of the company.

*Translated by Henry B. Binsse from a report by the Director in Chief of Mines at Liege, M. V. Leckat.

The Battle of Ludlow

By L. C. Paddock*

SYNOPSIS—A complete account of the action at Ludlow showing the battle was really an attack on the militia and not a defense of the tenters against military violence. The strikers killed one girl in bed; the women and children destroyed in the death pit were probably smothered before the tents were burned.

The fighting at Ludlow lasted from early Monday morning, Apr. 20, until late Friday evening, Apr. 24, at which time General Chase arrived with reinforcements and a truce was declared. On Monday morning, a few minutes after 8 o'clock, a letter was presented at headquarters at Ludlow by a woman of foreign nationality, asking that her husband be gotten out of the tent colony. Many times previous to this various people had been taken out of the tent colony by troops stationed at or near Ludlow.

The Corporal, Patten, in charge of the train detail was sent to the Ludlow tent colony to get this man and was told that there was no such captive there. Returning he informed Major Hamrock of this, who then called Louie Tikas, the Greek, by phone asking him to come over to camp, which Louie refused to do.

THE MILITIA GATHERS

As the people in the tent colony were gathered around in small groups in rather a suspicious manner, Lieutenant Lawrence, who was in command of the detachment stationed at Cedar Hill one and one-half miles southwest of Ludlow, was notified by telephone to come down a little earlier than usual for drill. Louie, the Greek, called up Major Hamrock stating that he would meet him at the depot, Major Hamrock accepting and going to that rendezvous.

Lieutenant Lawrence was again called on the phone by Hamrock who ordered him to bring the machine gun. Lieutenant Lawrence then left Cedar Hill in command of the advanced guard which consisted of ten men. Upon arriving near Ludlow he left these men on Water Tank Hill while he rode on to Ludlow depot to report to Major Hamrock.

Lieutenant Lawrence called Major Hamrock's attention to the fact that groups of the strikers were armed with rifles and carried ammunition and were running back and forth, some of them having started for the cut on the Colorado & Southeastern, which is east of Ludlow. The main body of national guardsmen arrived from Cedar Hill under the command of Lieutenants K. E. Linderfelt and M. C. Bigelow and consisted of fifteen men.

THE OPENING SHOTS FIRED BY COLONISTS

Louie Tikas left Major Hamrock, telling him that he would stop the strikers. Major Hamrock gave Lieutenant Lawrence orders to take up a position on Water Tank Hill and immediately upon returning to the hill from the depot Lieutenant Bigelow was sent with seven men to take up a position south of the Colorado & Southeastern R. R. cut, Lieutenant K. E. Linderfelt returning upon Water Tank Hill proper and Lieutenant Lawrence swinging over to the right of the Denver & Rio Grande tracks with five men.

The strikers, about three hundred in number, having gained the cover of the cut on the Colorado & Southeastern, opened fire on the detachments under Lieutenants Lawrence and Bigelow. Immediately afterwards another large group of strikers which had gone north and northwest from the tent colony toward the arroyo and the steel bridge, opened fire on the military camp at Ludlow which was southwest of the tent colony.

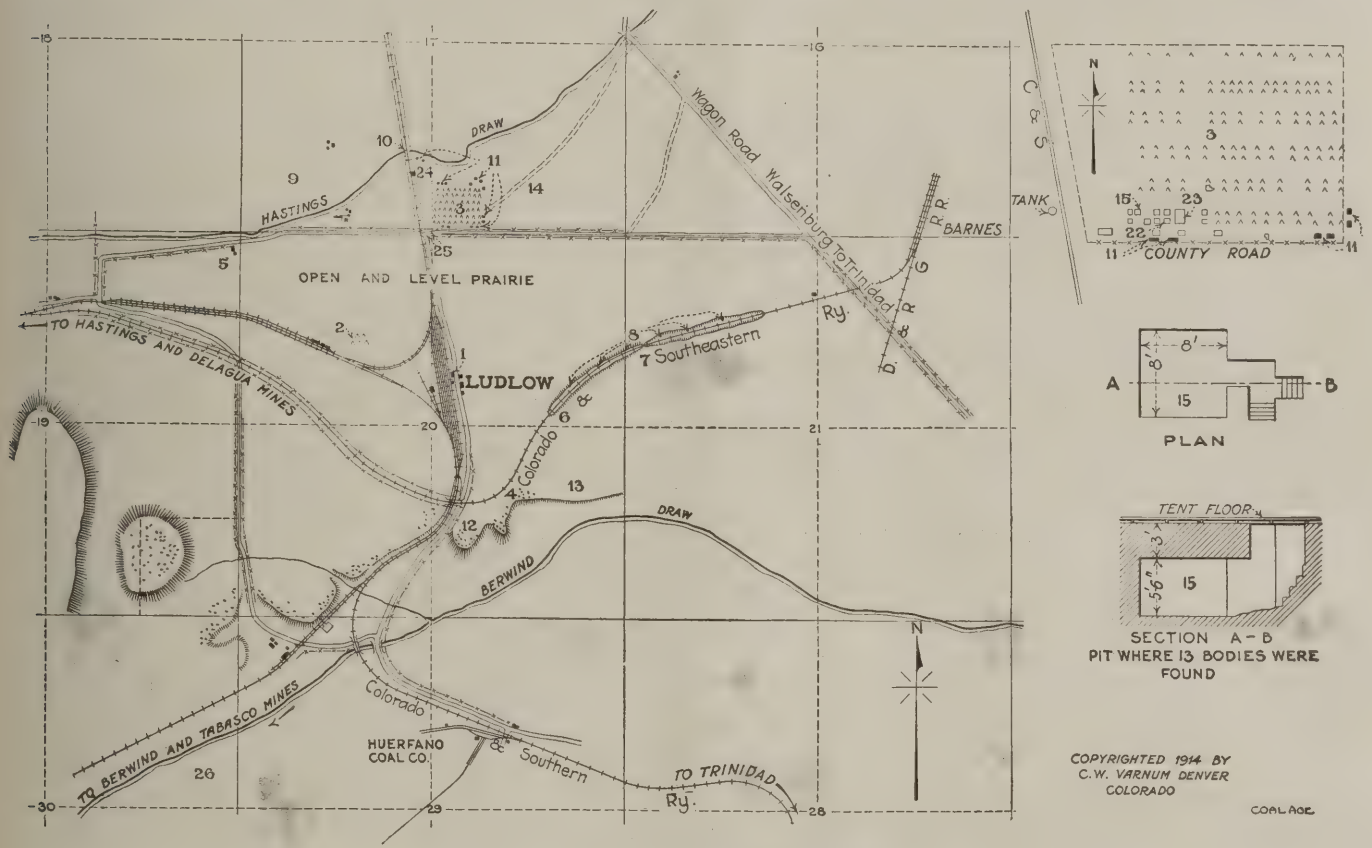
Before the firing started a large group of women and children, numbering about four hundred, left their homes running northwest to the arroyo. There were about thirty shots fired at the detachments of the National Guard south and southeast of the cut on the Colorado & Southeastern under Lieutenants Bigelow and Lawrence, before the order was given to commence firing. General Chase had been called on the long distance telephone by Lieutenant Benedict, Major Hamrock's adjutant, from the military headquarters at Ludlow, notifying the general that firing had started.

View of the Iron Bridge near the Ludlow Tent Colony and Three Views of Destruction Wrought by Strikers

*Editor the "Daily Camera," Boulder, Colo.

Note—This article appeared in the "Daily Camera" and we are indebted to the same paper for the photographs from which these illustrations are prepared.

Major Hamrock, after returning from the depot to the military camp at Ludlow, took up a position near cars south of this camp on the Colorado & Southeastern, from which point he could see very well the positions being taken by his own men.



NO PROFESSIONAL MINE GUARDS

Soon after firing started, three bombs which had been provided to use in calling assistance, were set off and Lieutenant Benedict was sent by Hastings cañon to the west to take charge of the men who would come to the Guard's assistance from that point, belonging to Troop A. None of the 18 men who came out of Hastings cañon, members of Troop A, were employed as mine guards but were employes at the mine, one a doctor and several being mechanics and miners.

On the right of the line a member of Lieutenant Lawrence's command, Private Martin, received a wound in the neck. Lieutenant Lawrence was forced back from his position on the extreme right, being forced to withdraw without the body of the wounded Martin, whom he left in a small draw. As Lieutenant Lawrence had been forced back on the extreme right the strikers had been able to deliver a cross-fire on Lieutenant Bigelow, whose position was south of the Colorado & Southeastern cut, forcing Lieutenant Bigelow to retire from that point. Retiring, Lieutenant Bigelow swung around to the right, meeting Lieutenant Lawrence and received orders to take up a position upon a knoll which was less than 150 yd. west of another point occupied by the strikers and to do what he could to recover the wounded Martin, who lay in a draw between these two points. Lieutenant Lawrence retiring and taking up a position 600 yd. to the rear, covering the position held by Lieutenant Bigelow.

As Lieutenant Bigelow had but five men with him at this point and was greatly outnumbered by the strikers east of him and those along the Denver and Rio Grande tracks, he was forced to retire from his position on the small knoll after having had one of the members of his command, Private Purcell, wounded, Private Purcell being hit by a soft nosed bullet in the left arm a little over two inches below the shoulder, which coming in contact with a bone, part of it lodged in the chest, and part in his back.

After Lieutenant Lawrence had returned to Water Tank Hill, Lieutenant K. E. Linderfelt forced his way down to the Ludlow depot, taking up a position at that point, having three or four men with him and delivering a fire into the west end of the cut of the Colorado & Southeastern. Major Hamrock not being able to get General Chase on the long distance telephone from military headquarters, as the line had been cut, succeeded in getting General Chase shortly after one o'clock at the office of the Cedar Hill Coal & Coke Co. near Ramey. He was notified by General Chase that reinforcements would come out during the afternoon from Trinidad with more ammunition. Captain T. C. Linderfelt and Lieutenant R. J. Linderfelt, having arrived about noon, were left in command at the Ludlow station by Lieutenant K. E. Linderfelt who returned to Water Tank Hill, Lieutenant Bigelow being sent to work with Captain T. C. Linderfelt by orders of Major Hamrock.

PLAN OF THE BATTLEFIELD OF LUDLOW

The numbers of men given here at first seem grimly humorous as describing an "army" and as designating one party in a "battle." When we think, however, of the greater number of adversaries and realize how the size and power of the smaller force has been misrepresented, the recital of the men engaged appears pathetic rather than humorous. The figures on the map are as follows: (1) Ludlow Station. (2) Major Hamrock with the army center (four men). (3) Ludlow tent colony. (4) Water Tank Hill, Lieutenant Lawrence with 22 men and a machine gun until 3:30 p.m., when Captain Carson arrived with another machine gun and 46 men. (5) Lieutenant Benedict with left wing of eight men. (6) and (7) Machine guns after about 4 p.m. (8) About 250 or 300 Greeks, etc., 9 a.m. until about 4 p.m. (9) Private Phillips mortally wounded. (10) Steel bridge. (11) Strikers to the number of 250 to 400 in rifle pits, some of which were of the latest and best military types. (12) Captain Carson with machine gun and 46 men arrived here at 3:30 p.m. (13) Private Martin wounded about 10 a.m. Body recovered about 10 p.m. (14) John Lawson, strike leader, in automobile about 11 a.m. (15) So called "death pit," which is reproduced in plan and elevation in lower right-hand corner (22) Tent marked "Lawson's Headquarters." Over 19,000 rounds of ammunition in boxes were found here, and among them about 400 Ely's explosive elephant cartridges. (23) Union headquarters. (24) Tikas, Rubino and Tyler captured. (25) Same men killed. (26) Cedar Hill. (16) to (21) and (28) to (30) are section centers.

FIRE FROM TENT COLONY

Several times during the afternoon small details under the command of Captain T. C. Linderfelt, aided by Lieutenants R. J. Linderfelt and Bigelow, were able to push their way through to the north end of the string of box cars and freight cars standing in the yards west of the depot, but were unable to go any further because of the fire they received from the rifle pits on the south side of the tent colony, the tent colony and those northwest of the tent colony in the direction of the pump house and the steel bridge.

MUTILATION OF MARTIN

Captain Carson arrived from Trinidad with about thirty-six men with ammunition and a second machine gun, which was in use during the fight. Captain Carson detrained at Rameyville and immediately advanced to the aid of Lieutenant Lawrence on Water Tank Hill. After Captain Carson's arrival several attempts were made by Lieutenant Lawrence to recover Martin's body but with no success. Not until 9 p. m. was he able to reach it. He found Martin's body terribly mutilated. Not only had he received a wound passing through his neck but he had been shot directly from above as he lay on the ground. This shot passed through his mouth tearing out two teeth and blowing off the top of his head. Not only that but his face had been caved in by a blow with the butt end of a rifle, his nose being broken and blood oozing from both ears. He had also been shot twice through the body at the waist.

The strikers holding a position in the cut on the Colorado & Southeastern were forced out of this position in the direction of Barnes on the Denver & Rio Grande about 5 o'clock in the afternoon.

THE BATTLE SHIFTS TOWARD THE TENTED TOWN

About the same time orders were given to Captain T. C. Linderfelt and the officers with him at the Ludlow depot to aid in the taking of the steel bridge over the arroyo, northwest of the tent colony, as Lieutenant Benedict had been able to force his way from the west and occupied a position in a couple of ranch houses about 400 yd. west of the bridge.

Captain T. C. Linderfelt with Lieutenants Bigelow and R. J. Linderfelt with 10 men, taking advantage of the cover afforded by the Colorado & Rio Grande tracks, had been able to take up a position just south of the road going west to Hastings, about seventy to eighty yards southwest of the tent colony. About this time Captain Carson arrived with a support and took up a position on the right of Captain Linderfelt. During this time they received a hot fire from the strikers located in the pits in the southwest of the tent colony and those in the tent colony proper.

The two machine guns which had been placed, one on the east side of Water Tank Hill and the other at the cut on the Colorado & Southeastern which had been taken, were firing at the steel bridge and the rifle pits along the south bank of the arroyo. The troops, under Captains T. C. Linderfelt and Carson, returned the fire of the strikers located in the pits along the south bank of the tent colony.

THE TENTS CATCH FIRE

The volley fell among the tents. It was at this time that a tent in the southwest part of the colony took fire the blaze shooting up through the roof. At that time there

LUDLOW TENT COLONY AFTER CONFLAGRATION

were no troops east of the Colorado & Southern tracks. Several of the men were able to get across the Hastings road underneath the water tank. Throughout the night there were constant explosions of ammunition, giant powder and dynamite in the tent colony. The fire was also aided by a strong wind from the southwest.

After the sixth or seventh tent was afire, the cries of women and children were heard from the tent colony. This was the first intimation the troops had had during the day that there were any women and children left in the colony. A great number of women and children had been seen leaving the Village before the firing opened about 9 o'clock in the morning. The order was immediately given to cease firing and all ran into the tent colony to rescue women and children left there by the strikers.

THE AIR-TIGHT PITS

During the time that the rescue work was going on the troops engaged in this work were constantly under the fire from the strikers situated to the north of the tent colony and to the northwest toward the steel bridge. These rescuers made excellent targets in the glare of the fire. Various obstacles were encountered by the men and officers engaged in the rescue work in order to get the women and children out of the pits in which they had been placed. At one pit where Lieutenant Bigelow rescued a woman and children, two trunks and a carpet had to be removed and a trap door opened in order to get into the pit where the women and children were. Similar boards were found over the pits by others engaged in the same work. The troops about this time started running for the cover offered by the Colorado & Southern R. R. tracks, taking the women and children, because they were told that a large quantity of dynamite was in one of the tents which was at the time on fire. They had no sooner reached cover when this tent went skyward, spreading sparks all over the colony. Many of the soldiers again returned into the tent colony to go on with the work of rescuing the women and children.

THE WHITE FLAG

At this time a buggy drove out of the southeast corner of the colony, driving west on the Hastings road. The occupants of this buggy carried a white flag and upon crossing through the line one of the occupants turned around and opened fire on the troops. The fire was returned with the result that one of the occupants and the horse were shot. A Colorado & Southern freight train coming in from the north and slowing up to take water at the tank allowed the strikers in the pits north of the colony and those near the pump house to get away to the arroyo.

Lieutenant Benedict, who had held a position in the ranch houses west of the steel bridge during the afternoon, sent the men under him back to Hastings after the tent colony caught fire, as they did not have uniforms on and he did not want them to mix with the men in uniform. They took two men who had been wounded during the afternoon.

ONE MINE GUARD AND A STRIKER KILLED

One of these men, Phillips by name, died a week later in the Pueblo hospital from his wound received that afternoon. Captain Linderfelt, who returned to the water tank from the steel bridge, was sent back to hold the steel bridge by order of Major Hamrock.

Captain Linderfelt left Lieutenant Connor, who arrived with Captain Carson from Trinidad during the afternoon, with a couple of men at the pump house. At the steel bridge the body of a striker was found. This striker had been shot by a steel jacketed bullet making a clean wound through the head. The steel jacket bullet is a service ammunition used by the armed forces of the United States and the only kind authorized by modern warfare.

DEATH OF LOUIE TIKAS WHILE ATTEMPTING TO ESCAPE

Shortly after this Louie Tikas was captured by Lieutenant Connor at the pump house, and Filer and Rubino were made prisoners at the steel bridge by the detail under the command of Captain Linderfelt. The latter leaving Lieutenant Bigelow in command at the steel bridge went to the water tank himself. Lieutenant K. E. Linderfelt, after the capture of the three men, went to the Ludlow depot to notify Major Hamrock. After he left the men in charge of the prisoners they were fired on from the strikers on the east side of the tent colony, the men immediately taking to cover. The prisoners, taking advantage of this, tried to escape, with the result that they were shot.

Major Hamrock placed his outposts about midnight and later summoned the officers to a meeting at Cedar Hill to discuss the plans for the ensuing day, Lieutenants Bigelow and Connor being left in command at Ludlow during this meeting.

BOTH SIDES REINFORCED

Early in the afternoon, during the fight on the 20th, Major Hamrock received word of about 250 strikers coming from Aguilar, Rugby and Rouse to reinforce those at Ludlow. He notified the people at Delagua and Hastings to get out into the hills and to watch the trails from Aguilar.

A group of negroes working at Hastings, about twenty to twenty-five in number, led by a negro who had been a first sergeant in the 24th U. S. Infantry, had taken up a position in the hills two and one-half miles west of Ludlow. Hamrock also notified the people in Berwind cañon to get into the hills and look out for strikers who were coming from Segundo toward Tollerberg. At about midnight he received word of a large number of strikers, about 300 in number, coming from Trinidad.

The troops were reinforced early Tuesday morning by Company C, Second Infantry, from Lamar, and by a small detachment of troops from Walsenburg. These, with the reinforcements received during the afternoon of the 20th, brought the original number of 44 troops at Ludlow up to 168 and 19 officers. Major Hamrock received a call for aid

from Hastings, sending a small detachment there, the strikers retiring as soon as the detachment arrived.

STRIKERS SHOOT FOUR MEN AND ONE GIRL

The next day a similar call for help was received from Delagua and again as soon as the troops arrived the strikers retired back over the hills in the direction of Aguilar, after having killed four men and shot a 14-yr-old girl while still in bed at Delagua, and shooting all the livestock and various domestic animals at the ranches in the neighborhood. These same strikers later burned up the cañons around Aguilar.

THE DEATH PIT

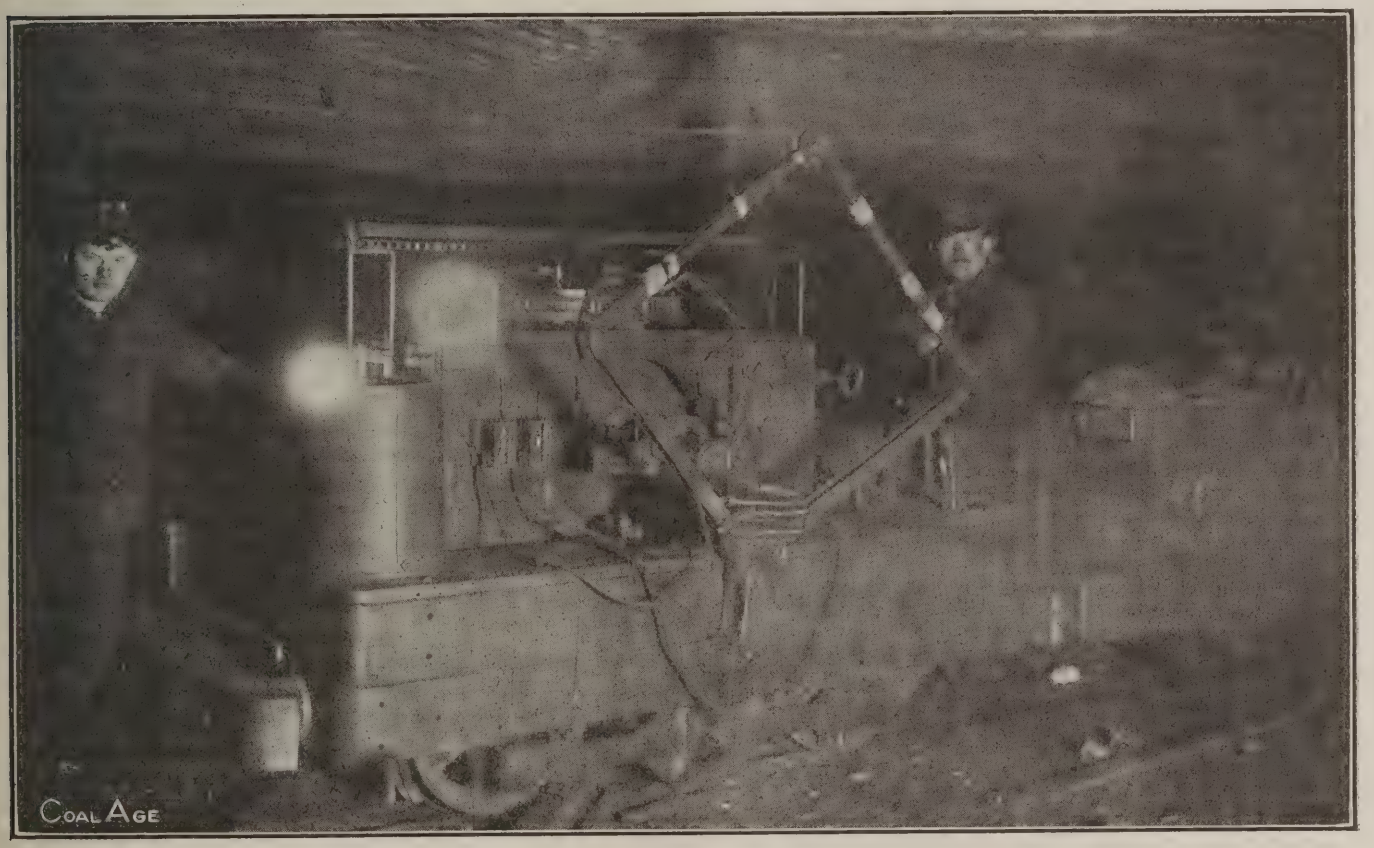
Tuesday morning, the 21st, a pit was discovered under what had been one of the tents in the colony and containing the bodies of 2 women and 11 children. Lieutenant Benedict and Dr. Lamme of the medical corps immediately went to investigate, finding that none of the bodies showed any evidence whatever of bullet wounds and that the victims had been suffocated and had been dead some time prior to the time the fire started in the colony.

A number of eminent physicians, after having seen the pit where these 2 women and 11 children were found, stated that 13 people could not live more than two hours in that pit without being asphyxiated. It was 7x8x5 ft.

DUMDUM AND EXPLOSIVE BULLETS

During the time of the rescue work in the tent colony a large quantity of ammunition was taken from the tents, some 19,000 rounds being taken from one marked "HEADQUARTERS JOHN R. LAWSON." There were 11 cases containing 1,000 rounds each from which the seals had not even been broken and 500 rounds of 45.70 dumdums. There were 200 rounds of Ely Express, calibre 45.100, a soft nose bullet containing an explosive cap in the end. Upon coming in contact with a human body the head would immediately explode and spread the lead.

All the ammunition taken from the tent colony was soft-nose ammunition. Bullets of this character are not used by the forces of any civilized country at the present time. The troops at Ludlow were surrounded by about 1200 strikers when General Chase arrived on Friday afternoon, April 24.



The number of substances which are used for electric conductors in commercial work is limited to three of the metals, namely, copper, iron and aluminum. Of these, the first is preëminently the best, while aluminum and iron come next in order.

An Historical Mining Locomotive

By H. C. Spaulding*

SYNOPSIS—The second electrical mining locomotive installed in the anthracite region was of Thomson-Houston manufacture, and has been in operation since 1889 and is still running.

Through the courtesy of The Society for Electrical Development, we publish herewith an illustration showing a mining locomotive which is not only interesting from an historical standpoint, but unique in its record for long and continuous service. This machine was installed at the Hillside Colliery, in 1889, and is still in satisfactory service. It was the second to be put in operation in hard-coal mining, the first having been built a year or two before for the Lykens Valley Coal Co., of Lykens Valley, Penn., by the Union Electric Co., of which W. S. Schlesinger was chief engineer.

The Second Electric Locomotive to Be Installed in the Anthracite Region

The locomotive shown in the illustration was the first to be built by the Thomson-Houston Electric Co., at Lynn, Mass., and was designed largely by C. J. Van Depoele, who was at that time actively engaged in the development of various types of mining machinery, including coal-cutting machines, reciprocating drills, pumping apparatus, etc. The adoption of electric haulage in place of mules was due to the farsightedness and enterprise of Capt. W. A. May, then superintendent of the Hillside Colliery, and now general manager of the Pennsylvania Coal Co.'s properties.

This machine was rated at 40 hp., had a 3-ft. gage, and

*Society for Electrical Development, 29 W. 39th St., New York.

was 9 ft. 7 in. long and 5 ft. 3 in. wide over all, with a height of 5 ft. 6 in. above the rails. As originally built, it weighed 10,500 lb., but 18,000 lb. of pig iron was added later as a dead-load to increase capacity for drawbar pull.

The above-ground installation consisted of a 60-hp. Armington-Sims engine belted to a 2-pole "50-hp." Thomson-Houston generator of the type made familiar by the Siemens & Halske Co. in Germany. Connection from the switchboard to trolley wires was made by No. 0 "Clark" wires inclosed in gas pipes, as a safeguard against mechanical injury. This fact is noticeable in view of the practice generally adopted later for pipe-inclosed wiring.

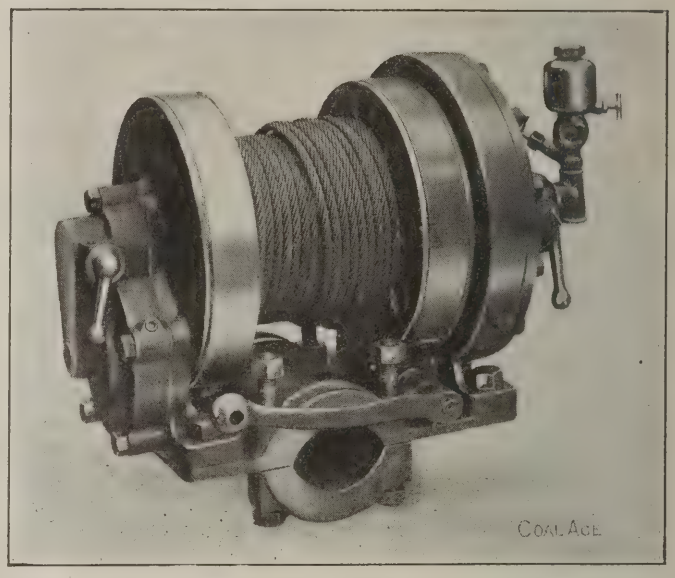
In the Lykens Valley installation worn out rails were used for the trolley contact, being joined end to end by copper bonds, but in the Hillside Colliery the trolley was a continuous No. 0 hard-drawn copper wire supported by insulators which later became generally known as the mining or "barn" type, fastened to the roof of the gallery by expansion bolts.

The electrified part of the track ran for about ½ mile in either direction from the foot of the shaft. It is interesting to note that previous to the electrical installation the galleries were dripping wet all the time owing to the condensed "steam" from the mules, and that after these animals were replaced by the electric locomotive this feature entirely disappeared.

In the construction of the locomotive itself, a single double-pole motor was used, the power being transmitted from pinions on the armature shaft through idlers to the driving shaft, which by the ordinary block and slot construction actuated the rods on either side connecting the two pairs of wheels. The crankpins were placed at 90 deg. from each other to avoid dead points. This construction allowed sufficient flexibility for inequalities of the track and movement of the motor with reference to the wheels.

As will be noticed from the illustration, the trolley was of the "lazy tongs" type, upward pressure against the wire being secured by the tension of spiral springs tending to "close up" the lower members.

It is interesting to note that the first electrically operated pump to be installed in the hard-coal country had been put in operation in the near vicinity only a short time before, and that this pioneer locomotive was followed not long afterward by one of 60 hp. of the "turtleback" type, since generally adopted for this class of work.



The "Little Tugger" Hoist

A new type of hoist has recently been placed upon the market by the Ingersoll-Rand Co., 11 Broadway, New York City. It is intended for light lifting, having a capacity up to one-half ton and, due to its small weight, which is under 300 lb. complete, it is particularly suitable for use as a portable hoist for mines, in contract work, for manufacturing plants, power houses and in railroad shops and ship yards.

Miners are using it in winzes, stopes and raises, for raising and lowering drilling machines, mountings, drill steel, timbers and miscellaneous material, for hauling cars in drifts and tunnels and for hoisting and lowering buckets in shallow shafts, and for other similar purposes.

The main base of the hoist is arranged so that it can be bolted to a timber or by means of a cap which comes with the hoist it can be clamped to a circular member, such as a mine column or arm, shaft bar or pipe. The dimensions of the hoist are 21¼x16½ in., and the height is 20⅛ in. The drum is 6 in. in diameter with a space of 7 in. between flanges. This will accommodate a length of 700 ft. of ¼-in. rope or 450 ft. of $\frac{5}{16}$-in. rope. The capacity is 1000 lb. with a rope speed of 85 ft. per min. at an air pressure of 80 lb. The machine operates with either compressed air or steam.

The motor or engine is of the reversible square-piston type, giving four impulses per revolution. There are no

Rear View of the Hoist, Showing the Three Control Levers

dead-centers and the machine will start in any position. The drum is mounted independent of the engine shaft and is operated through the medium of a clutch and gears. Safety is provided for by a powerful worm-operated band brake lined with "Raybestos."

The speed of hoisting is entirely at the will of the operator. When he releases the throttle, it returns automatically to central position, shutting off the power and stopping the hoist. Oftentimes the hoist will be used for haulage purposes and the release feature enables one man to handle this class of work. He can leave the control lever and carry the rope to the car.

There are no moving parts exposed, except the drum, all gears and shafts being covered. This is an especially desirable feature for underground operation where the light is none too good and where there is constant danger of workmen's clothes or bodies getting caught in the machinery.

So far as the practical electrical worker or engineer is concerned, electricity may be considered as one of the various forms of energy. Being such, it is never created, but is always produced at the expense of an equal or greater amount of energy in some other form. Electricity serves no useful purpose as such. It must be converted into some useful form of energy, such as mechanical, chemical or thermal, before it can be utilized. Electrical energy must always be used when it is produced, and produced when needed, for it cannot be stored. Because of the ease in transforming it into other useful forms of energy and transmitting it over great distances, electricity is being used more and more for commercial purposes. The ultimate nature of electricity is unknown. Recent discoveries would indicate that matter itself is composed of ultimate particles or charges of electricity.

Economy of Varying the Speed of Mine-Ventilating Fans

By a West Virginia Coal Mining Engineer

SYNOPSIS—In many mines it is found practicable to operate the ventilating equipment at one speed during working hours and at another during the night or on idle days. The two-speed induction motor is admirably adapted to such conditions.

The art of ventilating coal mines mechanically, dates back to the early days of the steam engine; the practice of economical ventilation is of comparatively recent birth.

Economy is becoming a much used word. It behooves us to know what it means according to the dictionary and to apply the principle to each of the different branches of our business if we are to keep up with the march of progress.

In mining coal, the cost of maintaining ventilation in accordance with the mine laws of the different states is one of the heaviest expenses encountered after operations have extended over a period of six or seven years. As time advances and the mine grows larger these expenses increase. If ventilating charges represent a large proportion of the total cost of work underground, any economies successfully brought to bear will have an effect in reducing the cost of production.

In considering a ventilating proposition, we have many factors to cover. Few words are required to describe this operation in an ordinary mine. The air is pulled through the galleries or tunnels of the underground workings by a centrifugal, or other fan, placed outside near the source of some certain power supply. It is very simple to describe. To do the work with a reasonable economy in power is not so simple.

It is desirable to comply with the mining regulations as far as possible, and deliver all the fresh ingoing air to the face of the actual working places. These points, from the nature of things, are furthest inside the mine and the most distant from the ventilating fan. Dozens of stoppings, overcasts, doors, etc., may be required to control the air current and carry it to where it is needed. If these stoppings could be built completely air-tight, an efficient ventilating layout would result. We are only poor weak mortals after all, and our efforts to build perfect structures in the darkness of a coal mine—or anywhere else—are not always crowned with success.

The longer a tunnel or airway is, the greater the number of stoppings there may be connected with it; and the greater may be the air lost through leakage. Again, if the pressure on one side of a stopping is decidedly greater than it is on the other, a proportionately greater amount of leakage will occur.

These losses are cumulative, and there are conditions where all the air is lost through stoppings, etc., before it reaches the face of the workings where it is needed. To repair the structure or stoppings in such a case requires time and labor and material. How much can be economically spent?

Airways of too little area require current at a high velocity in order to pass the volume required for thorough ventilation. By clearing out obstructions, and widening or multiplying the airways, the velocity is reduced and power saved. How much can be economically spent for such a purpose?

Conditions Change Rapidly

These questions are capable of solution only for short periods. Conditions change from week to week. As the workings extend underground, the amount of air required is increased, the resistance runs up, the number of stoppings multiply, the current of air may be lengthened or shortened. All of these things take place, resulting in a change in the amount of work required of the fan. If, by making repairs, extensions and changes, costing, for example, $100, the fan is relieved of 10 per cent. of its work, we have something to show on both sides of the account, and can decide whether or not the money has been well spent, if we know the amount of power saved and its cost per unit.

There are few cases where the cost of power per horsepower-hour is known in installations where a steam engine is used for driving the fan. The practice usually is to operate at a certain number of revolutions per minute, this speed being maintained by opening and closing the throttle valve. This critical speed is governed by the needs of the mine. If there is "bad air" on "Third Right," the foreman may "speed 'er up" a few revolutions. Or, again, the drivers are "not able to keep a light," in another part of the mine. In this case the fan may be "slowed down a little."

Under such conditions, and they exist more generally than one would imagine, the cost of power used cannot always be figured accurately. In many instances it is not known at all. The mine, however, may be amply ventilated at some one of the different speeds at which the fan is run. This particular speed, whatever it is, is the proper one at which the fan should be driven during the time when the underground operations are in full activity.

Where a mine is equipped with a fan of ample capacity, and has airways as well as underground structures in fair condition, a certain number of revolutions of the fan will furnish a sufficient amount of air to comply with the mining law and to fully ventilate the mine when it is producing its maximum tonnage. Such ventilation will require the maximum horsepower applied to the shaft of the fan.

During the hours when the mine is not producing coal, say at night, on Sundays and on holidays, only a fraction of this ventilation is needed. In mines where no inflammable gas is found, tests have shown that at night and on idle days, about half the full ventilating current is sufficient for all needs and all the demands for safety.

Under conditions such as we have outlined, a steam-driven fan can be slowed down to, say, half the speed used in the daytime, and the volume of air will be reduced in almost the same proportion. The steam, however, will vary in pressure, and this, too, will further vary the speed of the fan as well as the volume of air passing.

An engine running under such conditions is extremely inefficient, for the reason that the horsepower delivered to the shaft of the fan at half speed is practically one-fifth that delivered at the full speed, according to numerous recent tests. Where electric power is available, we should be safe in recommending its use for a drive, if for no other reason than to obtain a contant speed of rotation.

High Night Fan Speed Is Useless

In nongaseous mines, or others, where at night, etc., there is required only half the ventilation that is used in the daytime, it is needless expense to use more. Those officials who are responsible for the safety of life and property, after due and careful consideration of all the conditions, should be able to decide as to what amount of air may be used at night, etc.

Having properly decided that full speed and half speeds are safe for the operation of a particular mine fan, any other speed is not only unnecessary but wasteful in power. In other words, if half speed will fully meet the requirements in the way of ventilation, it is unnecessary to go to the expense of furnishing other ratios.

If a speed-regulating device were supplied as in the case of a steam engine, for example, the control of the power consumption, and therefore to a certain degree the cost of ventilation, would be in the hands of a comparatively irresponsible attendant who cannot be depended on to do one thing the same way every time. A motor capable of running at full speed, whatever that may be, and at half speed, fills the requirements of fan drive fully.

Once it is installed it assumes all responsibility as to the speed of the ventilating apparatus. It operates at either one or the other of its two possible speeds, and the fan, as a result, is either handling its full prescribed capacity or approximately half of it.

Occasions arise which demand that the maximum rotation of the fan be changed, either increased or decreased. Such changes can be well and cheaply made by substituting a different diameter of pulley on the motor shaft, when a belted installation is being considered.

The power saved by making the high-speed rotation exactly what is needed to fully ventilate the mine, and no more, when underground conditions are reasonably good, soon amounts to enough to pay for an extra or different driving pulley, or even several of them.

A Bibliography on the Export Trade

By F. R. Wadleigh*

SYNOPSIS—Although a few American companies have conducted exhaustive investigations into the export trade, the general knowledge on the subject is limited. Recent urgent requests for information along this line have made it seem advisable to publish a bibliography of the available data. As pointed out by the author, it would be difficult for one man to compile a list that would cover the subject in all its ramifications, and readers are invited to contribute additional or supplemental notes.

Interest in the exportation of coal is quite pronounced at this time, as is shown by the numerous inquiries regarding possible markets, competitive coals and prices, credits, freight rates and ship tonnage.

The subject is such a large one, comprising, as it does, every phase of coal handling from mining and geology to the actual burning of the coal, together with economic and political questions of the greatest importance, that a book of good size could readily be written on it. I have seen one private report, covering export possibilities to but one set of markets, that comprised 392 pages of typewritten matter. New conditions that have arisen as a result of the war now going on make the export question a matter of present and vital importance, and a knowledge of its ramifications and conditions absolutely necessary to those interested. To assist in obtaining such knowledge, I have made up a list of books, articles and public reports that have a bearing on the subject; in short, a bibliography of the coal export trade, incomplete probably, but none the less of some value. I would suggest that the readers of the Coal Age add to this list by advising the editors of any articles that may have been omitted.

*Consulting Engineer, 426 Real Estate Trust Building, Philadelphia, Penn.

Foreign Journals

As England leads the world by a wide margin in the export of coal, it is natural that most of the data on the subject should be found in English publications. The two leading English coal papers, the *Colliery Guardian* and the *Iron and Coal Trades Review*, publish each week, letters from all of the English shipping ports, giving prices, foreign contracts and inquiries; they also give numerous items regarding coals and the coal trade in foreign countries.

The *Liverpool Journal of Commerce* (daily), probably the leading shipping paper of the world, devotes two whole pages of its Friday issue each week to coal and the foreign trade.

The *Cardiff Journal of Commerce*, controlled by Mr. D. A. Thomas, one of the world's greatest authorities on coal export, also devotes considerable space to the subject.

La Revue Noire, published at Lille, France, the leading French coal paper, also has regular reports from the various foreign coal markets, statistics, etc.

Neither the British nor our own government has published anything on the subject, with the exception of consular reports. The United States Government has, it is true, published two reports on the world's coal trade, but these are made up from consular reports, many of which are inaccurate and do not give the information desired and needed. I recently suggested to our government officials the advisability and value of getting together and printing a full and accurate report on the coal trade of South America, made from the standpoint of the coal sellers in this country, and giving the information they would like to have; this suggestion has not met with much favor, although it was admitted that such a publication would be useful and timely.

BIBLIOGRAPHY OF BOOKS

The Coal Question; W. S. Jevons; London; 1st Edition, 1865; 3d Edition, revised, 1906.

An inquiry concerning the progress of the nation and the probable exhaustion of the coal supplies. It is the standard book on the subject, dealing with it from an economic standpoint, entirely on the British side. Geology, costs, prices, economics, consumption, exports and imports, changes and progress of the coal industry and coal resources of various countries are among the topics dealt with. It is a most interesting book to anyone in the coal trade, with copious and valuable references.

The Coal Fields of Great Britain; Edward Hull; London; 5th Edition, 1905.

As its title implies, this work is devoted to the coal fields of Great Britain, their geology and extent. It also has valuable data on the world's coal fields, with some analyses, chapters on coal exports and duration of the coal supply.

Analyses of British Coals and Coke; Allan Greenwell; London; 3d Edition, 1909.

This is a compilation by the editor of the *Colliery Guardian,* giving analyses of British coals and coke, with map, description of the different coal beds, names of collieries and trade names of coals. It contains the only collection of analyses from all the British fields, but too much reliance must not be placed on these, as some are too old to be of value (1860), and the majority are of mine samples, probably selected. For instance, analysis of Cambrian Navigation (Admiralty) coal shows 0.62 per cent. ash, while a sample from an actual shipment of the coal from another source showed 3.46 per cent.

In comparing them with analyses and calorimeter tests of our coals, it should be remembered that in a majority of cases the results are stated in different terms from ours. Most of the tests were made with the Thompson calorimeter, which may give 300 to 500 B.t.u. lower results than would the bomb calirometer.

The introduction of this book contains valuable information on purchase, storage, calorific values and the meaning of coal analysis, the last named being especially good.

Hints to Coal Buyers; Charles E. Evans; Cardiff, 1909.

This contains maps and descriptions of the South Wales coals, coal docks, preparation, analysis, briquettes, notes on sales, including charter parties, and much other information on Welsh coals. Also, a supplement to the plotted vertical section of the Northumberland and Durham coal field. (John Kirsopp, Jr.)

New Castle, 1908.

Description and analysis of coals from this field, including names of collieries and seams, together with characteristics of the various coals. This is the only work of the kind on this field. There are several hundred analyses, collected from various sources, the authority being always given.

1905 Royal Commission on Coal Supplies; in three volumes; London, 1905.

A digest of the evidence, reprinted by the *Colliery Guardian* and revised by witnesses. This is a compendium of information on the British coal trade; it includes mining, selling, buying, use and exports. Some interesting statements are made on the competition of United States coals. It also contains quite a complete bibliography on coal mining, both foreign and English. Volume 3 consists entirely of evidence regarding the export trade. Volume 2 has a bibliography of works in coke, briquette making, spontaneous combustion, fuel economy, gas making and liquid fuel.

Coal; James Tonge; New York, 1907.

This is written entirely from the British standpoint. It describes foreign coal fields with analysis and values and gives a list of world's coaling stations.

Story of American Coals; W. J. Nicholds; New York, 1904.

This deals only with United States coals; it does not contain much information as to markets, but the export question is mentioned on pages 55 and 139, where reference is made to our competition with English coals and why we cannot compete in the world's markets.

Modern Practice in Fuel Contracts; Myles Brown; Wigan, England, 1911.

This gives a number of foreign coal-contract forms and specifications; also analysis of foreign coals.

Shipping and Freight Business Prospects; Year Book; Business Statistics Co., Ltd.; Cardiff.

This is a small annual publication reviewing the past years in the coal and shipping trades and the prospects for the coming year. Statistics on export coal, prices and freights.

South Wales Coal Annual; Business Statistics Co., Ltd.; Cardiff.

An annual publication devoted to the South Wales coal trade. It contains valuable and useful data on exports and coals generally.

North Country Coal Annual; Business Statistics Co., Ltd.; Cardiff.

An annual publication devoted to the Northumberland and Durham coal trades, with statistics and data on exports and output.

Buying and Handling of Steam Coal; Boston Chamber of Commerce, 1909.

This is compiled and written with special reference to coals for New England, but has valuable maps and data that apply to the export trade as well.

The Black Diamond Year Book.

This gives much data on our coal exports, analysis of coals and tonnages, with a complete directory of all mining companies.

Panama Canal Traffic and Tolls; Report by Prof. Emory R. Johnson to the Secretary of War, Washington, 1912.

This contains much valuable data. Chapter X, on coal facilities and costs *via* the Panama Canal and other routes, gives costs and coals used at different ports, analysis, comparative consumption of different fuels in actual use, etc.

The Coal Trade; published annually by the *Coal Trade Journal,* New York.

A compilation of data and statistics on the year's business. It has considerable data regarding exports scattered through it.

The Production of Coal; annual publications of the U. S. Geological Survey, included in "Mineral Resources of United States."

This gives data on exports, the world's coal consumption, etc.

The Coal Resources of the World; Three Volumes and Atlas; an inquiry made under the auspices of the Second International Geological Congress; Toronto, 1913.

Descriptions of the world's coal fields, with outputs, resources and analyses. The United States and British sections are short and very general. The atlas is valuable and comprehensive.

The Trade of the World; J. D. Whelpley; New York, 1913.

A general consideration of the subject that does not go into the coal export trade particularly, but is of value to anyone interested, as showing the trend of the world's commerce and commercial activities.

Annals of Coal Mining and the Coal Trade: R. S. Galloway; Two Volumes; London, 1904.

An elaborate and interesting account of coal mining in England from the earliest times. It is of great value to anyone connected with the coal trade.

Foreign Trade in Coal; H. S. Jevons; Cardiff, 1909.

A valuable monograph giving data regarding the world's export coal trade, freight rates, German exports and rates.

Transport Facilities of South Wales and Monmouthshire; Clarence S. Howells; Cardiff, 1911.

Papers on the Export Question in Coal Age

Our Future in the Export Trade. F. R. Wadleigh. Dec. 28, 1912; Feb. 8, 1913; Mar. 8, 1913.

Discussion of our export trade in general. Short description of the Welsh coals, with analysis. Also, analysis of Pocahontas and New River coals, consumption of coal in foreign countries, markets and transportation.

Our Coal and Coke Exports in 1911. Editorial discussion. Jan. 6, 1912.

Discussion of statistics and their relation to the trade.

World's Consumption of Bunker Coals. Jan. 27, 1912. Statistics and discussion.

The World's Coal Production. Jan. 6, 1912.

Our Export Trade in 1912. F. R. Wadleigh. Jan. 11, 1912.

The 1912 trade and what it shows; the future possibilities and difficulties to be overcome.

The Price War in the Markets of the Pacific. Feb. 14, 1914.

West Virginia's Foreign Rivals in the Pacific Markets. Feb. 28, 1914.

West Virginia's American Rivals in the Pacific. Mar. 21, 1914.

General discussion of the future of the West Virginia coals in the West Coast markets. Gives comparative distance, prices and analyses and data regarding the cost of shipping coal by water to the gulf.

Effect of the Panama Canal. W. A. McCorkle, ex-Governor of West Virginia. May 30; June 20; July 11, 1914.

Effect of the Panama Canal on the World's Coal Markets. F. R. Wadleigh.

A criticism of ex-Governor McCorkle's article on West Virginia coals in the Pacific markets. Analysis of coals, distances, transportation, prices, possibilities of competition of different coals and oil, smokeless coals and briquetting.

Export Trade and the Panama Canal. Colliery Guardian (London). Extract from editorial. Feb. 21, 1914.

The Welsh Coal Field. Reprinted from *The Syren and Shipping.* London, 1906.

Describes the Welsh coal fields and coals, coal docks, railways and foreign trade and United States coaling stations. Also gives historical sketches of several of the large coal companies and description of their mines and coals.

Wealth and Prospective Development of the West Coast of South America. Journal of Association of Engineering Societies, Boston, March, 1908. A. Russell.

Gives data regarding coals and coal consumption. The coal fields and collieries of Chile.

Mining Journal, London, Aug. 21, 1909.

Describes coal deposits and coals used in Chile.

United States Consular Reports

Many of these reports give more or less information regarding coal in foreign countries, but usually the data are not of much value or use. A practical list of numbers is given below:

Uruguayan Coal Situation. July 6, 1912.

Ecuador Coal Imports. Mar. 20, 1914.

Coal in Bolivia and Peru. Feb. 10, 1912.

Conditions in World's Leading Coal Shipping Port. Apr. 10, 1914.

American Coal for Argentina. June 2, 1914.

Chilean Commercial Progress. June 16, 1914. Gives products and importation figures.

Increases of Fuel Consumption in Chile. June 3, 1914.

Iron and Coal Trades Review (London)

French Imports of Coal. 1912. Feb. 21, 1914.

Coal Exports Prices. (Editorial.) Sept. 5, 1913.

Prices of Exported Coal. (Editorial.) Sept. 19, 1913.

The World's Coal Production and Consumption. Apr. 3, 1914.

German Coal Industry in 1913. Feb. 13, 1914.

Coal Trade of the United States. (Editorial.) May 2, 1913. Discusses competition of Welsh and United States coals in foreign markets.

The Progress of German Coal Exports. July 4, 1914.

Italian Coal Imports and Bunker Coal. (Editorial.) July 19, 1912.

The British Coal Shipping in 1913. (Editorial.) Jan. 9, 1914.

A Statistical Review of German Coal Industry. Apr. 24, 1913. Complete data for 1913.

Journal of Commerce (Liverpool)

D. A. Thomas and His Future Connection with England and the United States. Interview and Biography. Feb. 21, 1913. Interesting comparisons between English and United States coals and coal mining.

American Coal Competition in the Mediterranean. July 19, 1912.

American Coal Export Trade. July 3, 1914. Statistics of Exports from Baltimore and Hampton Roads.

America's Foreign Coal Trade. With especial reference to Hampton Roads coals.

Colliery Guardian (London)

The American Coal Trade. (Editorial.) Dec. 12, 1913.

American and British Coal. May 9, 1913. Discusses the influence of the Panama Canal on coaling stations and bunker coal markets at Panama on the Pacific.

Black Diamond (Chicago)

Export number, Oct. 5, 1912.

American Coals Suitable for Export. J. S. Burrows.

Use of Fine (Small) Coal.

Export Statistics for Eight Months of 1912.

Advertisements of Three Large Coal Companies.

Some Data on Exports.

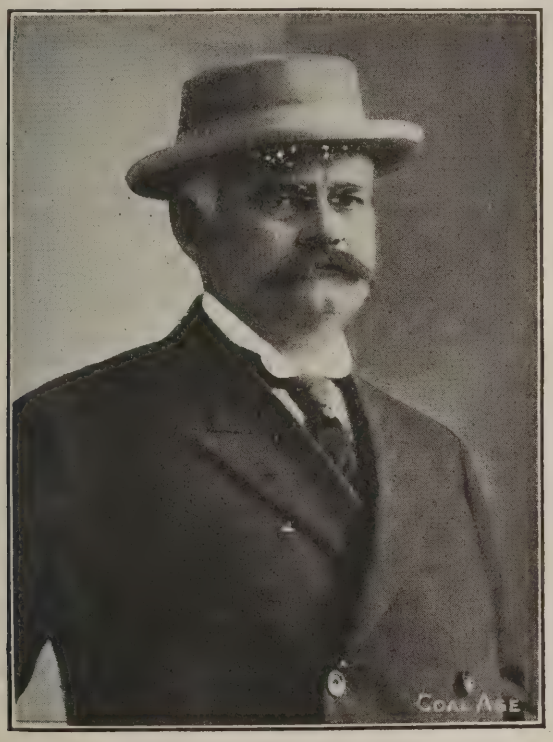
Beginning with 1913, a page in each week's issue is devoted to the United States coal export trade, giving statistics, prices and freights, extracts from foreign trade papers and consular reports, etc.

Shipping (New York)

In each issue under the heading "Coal Notes," are given various items on the export trade, including ocean freights.

Coal Trade Journal (New York)

Gives, in each issue, a list of prices of Welsh coals and ocean freight rates.



It must be understood that this list of books and articles on the export trade is by no means complete.

Who's Who in Coal Mining

John Markle

When we speak of America's independent anthracite coal interests, we must necessarily refer to the famous Markle family in Pennsylvania, for the two are practically synonymous. In fact, the history of the Markles is largely a history of hard-coal mining.

The creator of the firm of G. B. Markle & Co. was George Bushar Markle, who was born at Milton, Penn., July 1, 1817. This elder Markle started in Hazleton, Penn., as a clerk, advancing to bookkeeper, store manager and finally colliery superintendent. In 1857, after nine years of such training, G. B. Markle formed the firm which was later succeeded by the corporation now

JOHN MARKLE

bearing his name and operating four collieries in the Lehigh-Anthracite Region, with headquarters at Jeddo, Penn. No other anthracite property has such a record of 56 years of continuous operation under the same ownership and management by the same family interests. Most of the other independents have been absorbed by the railroad coal companies

Mr. Markle is known as the "father of the breaker," having designed the first one embodying real mechanical principles. His inventive mind also added many improvements to mine pumps, jigs, crushers and other machinery used in early anthracite mining. He gave up business in 1879, due to failing health, and died Aug. 18, of the same year, at the residence of his son John Markle, in Hazleton, Penn.

John Markle, the subject of this sketch, was born in Hazleton, on Sept. 15, 1858. He graduated from Lafayette College with the degree of mining engineer in 1880. Immediately following his graduation, Mr. Markle entered the coal business of his father as general superintendent of all the company's extensive coal properties in the anthracite region.

On the death of his father eight years later, John Markle purchased the entire interest of the Asa Packer Estate in the firm of G. B. Markle & Company, this interest ranking next to that of the senior Markle himself. This purchase gave Mr. Markle control of the property and caused him to assume complete management of the company's affairs.

In due time, Mr. Markle rebuilt the entire properties under his control, and today there is no evidence of any of the original buildings other than the miners' houses, even these having been greatly improved. He has increased the production at the Jeddo and Highland collieries from 360,000 tons in 1879, to 1,337,000 tons in 1913, and has guided the "Markle organization" to a high degree of efficiency. The G. B. Markle and Co. mines have worked steadily throughout recent years, affording a sharp contrast to the broken time worked by most of the other operators.

Mr. Markle's engineering ability was also shown by his work in connection with the Jeddo Tunnel, which is generally credited with being the largest drainage tunnel in the world. The construction of this huge underground waterway made possible the working of mines then thought to be hopelessly flooded, and makes the Markle mines at Jeddo and several adjoining collieries entirely self-draining. Short connecting tunnels could drain the Hazleton and other coal basins.

The tunnel is 7 ft. by 9 ft. and extends through five miles of solid rock. The cost of the work was in the neighborhood of $1,000,000.

In 1907, Mr. Markle suffered a serious impairment of his vision, but through the efforts of celebrated German oculists, the sight of one eye was saved. About this time the partnership of G. B. Markle and Co., of which he was managing partner, was incorporated into the present operating corporation of G. B. Markle and Co., of which concern, John Markle is president.

John Markle has inherited his father's fearless determination to stand for what is just and right, irrespective of any and all consequences. His success in the commercial and industrial world has netted him great wealth, but the possession of this he regards as a stewardship. It is his conviction that every man, if not incapacitated, should create more than he spends or destroys, irrespective of his position or inherited wealth.

Mr. Markle is known for his genuine desire to elevate his employees. No man could be more kindly in a practical way to those dependent on him. His charities are not heralded by the blare of trumpets, but they no less succeed in relieving those who are most in need. The beautiful marble library given to Hazleton is a memorial to his parents, and the recently completed casino, built at Jeddo is another tangible indication of his broad-minded generosity.

In 1884, four years after his graduation from college, Mr. Markle married Mary Robinson, daughter of Mrs. J. Hood Wright, of New York. He is a member of a long list of societies and organizations located in New York, Philadelphia and throughout eastern Pennsylvania. His home is at 723 Fifth Ave., New York City, although he still maintains his summer home at Jeddo.

Editorials

The Rights of Labor

The rights of labor are human and not superhuman. They should be rights, not privileges. Let the working man always remember that he is only a man and entitled only to a square deal, that even the successful, yet unfair, restrictions of capital by labor may prove veritable Pyrrhic victories in the end by putting one class of workingmen in the hands of another.

The Western Federation of Labor is about to become a branch or ally of the United Mine Workers of America. Already committees from both organizations are favorably discussing organic union. Our readers will pardon us, therefore, if we discuss the Western Federation, which is being fiercely attacked by the Industrial Workers of the World, or rather, perhaps, by a union more or less in sympathy with that organization. In fact, so severe is the disturbance that the Socialist officials in the town of Butte, Mont., have telegraphed for the state militia and word is received that Governor Stewart has ordered the Second Regiment of the Montana National Guard to mobilize at Helena, Mont.

The offices of the Anaconda Copper Mining Co. have been dynamited. Apparently that corporation committed the heinous crime of hiring Western Federation men against the wishes of the Industrial Workers of the World, who are requiring that every man must wear a button and enter their union and no other. The organization, not content with dynamiting Western Federation headquarters, disturbing their parades, driving out and killing their men, desire to arm themselves for an attack on the Anaconda Copper Mining Co. should the mines be closed down. They also threaten to burn down the city of Butte should federal troops or militia be sent to preserve peace.

We suppose that the United States will ultimately send troops and restore the *status quo* and will forbid any one to come to the mines to work, thus keeping Western Federation men from employment unless, being citizens or at least residents of Montana, one by one they are willing to face the violence of their enemies and in self-immolation enter the hostile camp. They may well be forbidden by the Department of War to engage themselves in numbers and at points outside the state, and the operators may be forbidden to purchase arms to protect them. For labor is no longer free. The stronger and more violent element has claimed the right to command the national forces and to control the situation. Even the majority of the miners does not rule as has been shown recently in Colorado and Nanaimo. Thus the miners who have set themselves against liberty have surrendered themselves by that act to violence.

It is to be hoped that recent events will convince the sober workingman, whose ascendancy is in doubt, but whose majority is unquestionable, that there are workingmen as also there are operators who need to be kept firmly in the narrow path of right behavior. No body of men can be left free of law and restraint.

For example, as the Grand Jury in Las Animas County, Colorado, has declared, the United Mine Workers of America have been in that county men of violence who should be curbed. National officers and leaders of the union, they say, have purchased and supplied arms to mobs and as a result there has been wholesale destruction of property and the killing and wounding of men, women and children by armed mobs made up of members of the United Mine Workers of America. They say that many persons connected with these outrages have been shielded and secreted by the miners' organization.

Clearly the union has in places proved that power can be abused by those who have it, regardless of the source from which that power is derived and from Butte the workingman may learn and he cannot know it too soon that the hand of the law must not be paralyzed or the heel of the mob will bear heavily upon the workingman.

Miner's Certificates in Arkansas

In January of this year, the Federation of Labor and the United Mine Workers of America in Arkansas, initiated an act creating a state mining board. This by the "Initiation and Referendum Act" required 14,000 signers. There were 18,000 on the petition.

On July 15, the Operators Association of Arkansas sought to have a decree entered against the petition, alleging fraud in obtaining signatures to the instrument, and on Aug. 13, Chancellor J. E. Martineau, of the Pulaski Chancery Court, entered a decree enjoining Secretary of State, Earl U. Hodges, from certifying the proposed act to the election judges. The Federation of Labor appealed the case to the Supreme Court, which is now on vacation and will not convene till Oct. 1, 1914. The state election will be over by that time, being held on Sept. 14. So the act cannot be passed by vote for two years.

This law requires certificates for mine managers, superintendents, mine foremen, "gas men," hoisting engineers, mine inspectors, fire bosses, pit bosses and coal miners. The latter must be able to pass an examination as "to their practical knowledge of mining coal." The law also states "that it shall be unlawful for any person to engage in mining coal without first having obtained a certificate of competency."

It is clear that under this law no one can mine coal but those who *have* mined it; thus all men who are not miners and even miners' sons are excluded. It is evident that the law would either be deliberately misinterpreted or it would, if also passed in other states, cause coal mining to become a lost art in a few years for the ranks of the coal miners could not be recruited. Not a word is said about laboring under a coal miner, as in the Pennsylvania law.

Either the law is made with the idea of evasion or else inadvertently the miner has made the walls so tight that his own children cannot follow the same profession as he

follows himself. It may be possible that evasion of the law is purposed for the miners are to have a majority on the board, one of the members is to be a practical mining engineer, one a mine operator and three are to be practical miners "actually engaged in digging coal" at the time of appointment.

Believing that every man should have the right to aspire to be a miner or a butcher or whatever you please, without being required to violate any law or asking any board to violate the law for him, we unhesitatingly condemn any such enactment as a gross interference with the rights of workingmen. Certificates for coal mining, such as the anthracite region of Pennsylvania has, are bad enough, but that is largely because of the racial differences of the people, which make it necessary for an English-speaking man to work for a Pole or a Slav and because it compels able miners from another state or nation to work for less competent men to get certificates. Also because these certificates have often been obtained fraudulently. But this law is objectionable in different ways. It would, if made nation-wide, close the trade of coal miner to all but those who are now so engaged.

Mine foremen or gas men under the provisions must have "five years' practical experience in mining coal," mine inspectors must have "five years' practical experience as an actual coal miner," and fire bosses and pit bosses, "five years' practical experience as a coal miner." The bars are let down to hoisting engineers, but they must have "practical knowledge of mining coal." It seems entirely needless that hoisting engineers should have such knowledge, but we must admit that we are assured that no attempt is being made to corner all positions for the advantage of the coal miner, for the requirement as to mine managers and superintendents is not any too severe. They must have "five years of practical mining experience."

We would suggest that the signers having two years before them make the proposed act more in accord with reason and also go over it carefully and see if they have not repeated themselves several times in Section 6 without any necessity. The act as drawn is quite vague. It has no definitions and it might be quite easy to evade some of its provisions because its application is to men of a given title and not to men performing specific duties.

Our Last Thought Is Too Often of Ourself

In our daily struggle for success we endeavor to be alert, yet cautious. We try to marshal our forces to the best advantage and waste as few shots and as little energy as possible.

Safety, Efficiency, Conservation are the ruling thoughts of our very existence. To reduce costs and eliminate risk are the chief aims of our life.

Too often, however, the last person we consider is ourself. We forget that we cannot discharge our duty to others unless we first fulfill our duty to ourselves.

The person who is negligent of his health and careless of habits that destroy body and character is not only useless as a member of society, but is a pernicious influence generally.

The prime essential of right living is a knowledge of the laws of our being. It is because the origin, development and decay of life are beyond our comprehension that we recognize the necessary existence of a great unknown power. The danger is that in giving reverence, we neglect obedience, and violate mandates written in nature's laws.

When a friend gives us a present merely through kindness, and not to enrich us, it is the giving we appreciate more than the gift; but when we are presented with a gift of great value, it becomes a trust, and we attempt to develop its possibilities.

Life is the greatest of all trusts; yet the great masses of humanity are ever ready to break the plainest and simplest of nature's laws. This is absolute evidence that we have not been properly taught.

Our violations are generally committed in youth, however; it is in middle life and old age that the punishment is imposed. If our carelessness brought immediate penalties, we would act differently.

An infant puts its finger in the candle, and the punishment is so immediate that one experience is sufficient for a lifetime. The anguish that so often fills many lives is usually the slow punishment of sins that comes after the lapse of years.

Arkansas Ventilating Methods

The double-entry system of mining is such a common method of operation in all the leading coal-producing states of the Union that it is remarkable to find that in the State of Arkansas where there is often gas, the operators are opposing its further introduction. We imagine that if in the States of Pennsylvania and West Virginia the laws were all wiped off the statute books and every operator were allowed to do as he pleased, only those people who mined coal for local domestic use in a small way would seek to return to the old inefficient single-entry system by which slow progress is made.

However, we feel that Arkansas is partly to blame for this condition because it has passed a law requiring crosscuts in headings to be spaced at 40-ft. centers, where there is no gas present and at 30 ft. or even a less distance where there is gas. Such a provision tends to support the operator in his preference for the single-entry system. The chain pillar is cut up until it has no strength and the method is needlessly expensive. In the States of Pennsylvania, the mine inspector is expressly forbidden to require that crosscuts be driven closer than 48 ft. apart even in rooms and the distance may be at his discretion 105 feet.

In fact, it usually is nearer the latter figure. Even in Colorado, which has an unusually stringent law, the inspectors are allowed to let working faces travel 60 ft. beyond the air current, which does not mean that crosscuts be placed 60 ft. apart, as canvasses can be used to direct the current.

But unreasonable as we consider this requirement of frequent crosscutting to be, we cannot see why any company should refuse to drive a double-entry and we believe that in time the irreconcilables in that state will learn that a more liberal policy pays. There is hardly a state in the Union where such mining as we illustrate in the article on the "Double-Entry System in Arkansas" could be perpetrated, for the waste of coal and mining developments have proved it everywhere to be a folly.

Sociological Department

The Lehigh Valley Meet

The first-aid movement at the collieries of the Lehigh Valley Coal Co., received added impetus at the third general contest, which was held on Saturday, Aug. 29, at Hazle Park, Hazleton. Vice-President and General Manager Fred M. Chase and other officials of the company were in charge.

Five teams, each representing the best in their respective divisions, participated in three full-team events. First place was awarded to the Westmoreland team of Wyoming, Lackawanna Division, of which W. D. Owen is superintendent. Derringer team, of Hazleton, Lehigh-Coxe Division, scored a tie with Westmoreland, both percentages being 99. The event was decided on the time taken by the contesting teams. Westmoreland completed the problems assigned in 27 min. and 45 sec., while Derringer consumed 29 min. and 16 sec. The Franklin team of Wilkes-Barre, Wyoming Division, also averaged 99, but took 34 min. and 5 sec. The Primrose team, of Mahanoy City, Delano Division, took fourth place with a percentage of 98⅔, while fifth place went to the Centralia team, of the Centralia Division, the average of that team being 97. Only the three leading teams were rated on the time consumed in performing their work, the other corps being placed solely on the merits of their performance regardless of their rapidity in action.

The high averages attained by every entry speak well for the training which the members have received. The men in direct charge as captains were given an opportunity to display their proficiency in an individual contest, and Simon Fellin, of the Derringer team, emerged the winner with an average of 99½, while Anthony Gludding, of the Primrose team, was a close second, his percentage reaching 99¼. John O'Neil, of the Franklin team, was only ¼ of a point behind Gludding, and O'Neil was tied with James R. Morris, of the Westmoreland team. The standing between O'Neil and Morris was therefore decided on the time allowance, which gave O'Neil the advantage. O'Neil finished in 3 min. and 45 sec., while Morris' time was 9 min. and 9 sec. John Wilson, of the Centralia team, performed his task in excellent time and made an average of 97½. It had been announced before this contest that the winner would be taken as a representative of the Lehigh Valley Co. at the meeting of the American Mine Safety Asosciation, to be held in New York City on Sept. 7. The captains acquitted themselves so creditably, however, that General Manager Chase made an announcement that every man who participated in the individual contest will also be taken along. This move on the part of the officials indicated the admirable attitude which they have assumed toward their first-aid men. When the announcement was made known to the big assemblage that packed the park theatre, prolonged applause arose.

The Westmoreland team was presented with the valuable silver loving cup, which the Derringer team, one of the best organized in the anthracite region, held last year and had high hopes of holding again. It will be put up for contest at the next general meet in 1915. The cup, in order to be retained permanently, must be won three times. Westmoreland has won it only once. As a further award, every member of the winning aggregation will be taken to the American Mine Safety Association meeting.

TEAM MEMBERS, OFFICIALS OF LEHIGH VALLEY COAL CO. AND JUDGES

The judges were Miss A. M. Anderson, a graduate of a New York hospital training school and who at present is superintendent of the Social Service Department of the Wilkes-Barre City Hospital; Dr. W. A. Lathrop, superintendent of the State Hospital, Hazleton, Penn., and Dr. Lawrence Thompson, of Wilkes-Barre, Penn.

After the awards had been made, General Manager Chase gave a brief address, in which he congratulated the men and commended them for the noble work which they are rendering in the service of suffering humanity. Thomas Thomas, general inside superintendent of the Lehigh Valley Coal Co., gave a splendid talk on first-aid work.

Before the contests started, John M. Lloyd, efficiency en-

THE TEAM OF THE WESTMORELAND COLLIERY, LACKAWANNA DIVISION; THE WINNING TEAM

From left to right .John F. Reynolds, mine foreman; Jas. R. Morris, captain; Edward Reap, Thomas Ridgeley, Walter Jacoby, Joseph Johnson, Fred Halpin. Rear row: George P. Gallagher, assistant division superintendent; G. F. Hileman, outside foreman.

gineer, delivered an address of welcome, in which he declared the purpose of the meeting. Charles F. Johnson, superintendent of Kis Lyn, also spoke and complimented the Lehigh Valley Coal Co. and its employees for what they are doing to conserve human life. At noon, a substantial lunch was served in the park dining room, and between courses brief talks were given impromptu by the officials. Among the guests were Alvin Markle, coal operator, of Hazleton; General C. Bow Dougherty, superintendent of the Susquehanna Coal Co., Wilkes-Barre, Penn.; H. Heffler, of Centralia; W. H. Davies, of Lehigh-Coxe, and J. H. Haerter, of Wilkes-Barre, Penn.

Efficiency Engineer John M. Lloyd was in general charge, M. W. Price in direct charge, and the scorekeepers were Herbert I. Quinn and M. E. Terwilliger. For the first time in the history of the Lehigh Valley first-aid contests, a time limit allowance was placed in the events. The affair was without doubt the most successful ever held by the company.

Five teams were entered in the first three events, each of the five divisions of the Lehigh Valley Coal Co. being represented.

OFFICIALS IN CHARGE OF MEET

From left to right: Atherton Bowen, scorekeeper; John Lloyd, efficiency engineer, in general supervision; Thomas Thomas, general inside superintendent of L. V. Coal Co., and M. W. Price, scorekeeper.

Event No. 1, for Full Teams—The problem was as follows: "Simple fracture of right kneecap. Compound fracture of middle third of left leg. Severe bleeding in spurts. Simple fracture of the jaw. Deep wound in palm of right hand." Time allowance, 15 min.

The judges and timers rendered decisions as follows in this event:

Franklin colliery team, representing the Wyoming division, 100 per cent.; time, 9 min. 55 sec. Primrose colliery, representing the Delano division, percentage 99; time, 11 min. 35 sec. Westmoreland colliery team, representing Lackawanna division, percentage 100; time, 9 min. 10 sec. Centralia colliery team, representing Centralia division, percentage 97; time, 9 min. 8 sec. Derringer colliery team, representing Lehigh-Coxe division, percentage 100; time, 9 min. 9 sec.

Event No. 2, for Full Teams—The same men who won the first event also won in this contest. "Compound fracture of the left forearm with severe bleeding in spurts. A simple fracture of right collar-bone. Crushed left foot. An open wound entire length of right shin bone and feet." Time allowance, 10 min.

The result of this event follows: Franklin colliery team, Wyoming division, percentage 98; time, 11 min. 40 sec. Primrose colliery, Delano division, percentage 97; time, 7 min. 35 sec. Westmoreland colliery, Lackawanna division, percentage 98; time, 8 min. 13 sec. Centralia colliery, Centralia

THREE OF THE CAPTAINS

From left to right: Simon Fellin, captain of Derringer colliery team, first prize; Anthony Gludding, captain of Primrose colliery team, second prize; James R. Morris, captain, Westmoreland colliery, third prize.

division, percentage 97; time, 8 min. 20 sec. Derringer colliery, Lehigh-Coxe division, percentage 92; time, 10 min. 2 sec.

Event No. 3, for Full Teams—"Fracture of pelvis on right side. Compound fracture of middle third of left thigh with severe bleeding in spurts." Time, 15 min.

The judges made the following announcement on this event: Franklin colliery, Wyoming division, percentage 99; time, 12 min. 30 sec. Primrose colliery, Delano division, percentage 100; time, 9 min. Westmoreland colliery, Lackawanna division, percentage 99; time, 10 min. 22 sec. Centralia colliery, Centralia division, percentage 97; time, 15 min. 54 sec. Derringer colliery, Delano-Coxe district, percentage 99; time, 10 min. 2 sec.

Event No. 4, for Individuals—The captains of each of the five teams which took part in the first three events were the competitors in the individual contest event. The problem was as follows: "A man in falling to the ground grasps an electric wire with his right hand. Rescue and give artificial respiration for 1 min. Treat for burns of the right hand. Time allowance, 9 min."

The results of this event follow: John O'Neill, captain of Franklin colliery, of Wyoming division, percentage 99; time, 3 min. 45 sec. Anthony Gludding, captain of Primrose colliery of Delano division, percentage 99¼; exceeded the time limit. James Morris, captain of Westmoreland team, Lackawanna division, percentage 99; time, 9 min. 9 sec. John Wilson, captain Centralia team, Centralia division, percentage 97½; exceeded time limit. Simon Fellin, captain Derringer team, Lehigh-Coxe division, percentage 99½; time, 5 min. Fellin was declared the winner of this event, having the highest percentage and having worked the problem well within the time limit.

The teams which represented the different districts were comprised of the following:

JUDGES OF CONTESTS
From left to right: Dr. W. A. Lathrop, Miss A. M. Anderson and Dr. Lawrence Thompson

Westmoreland colliery (winning team), representing the Lackawanna division—James Morris, captain, electrician; Edward Reap, assistant foreman; Thomas Ridgley, mason; Walter Jacoby, siltman; Joseph Johnson, fireman; Fred Halpin, subject.

Franklin colliery, representing the Wyoming division—James O'Neil, captain, assistant foreman; William Morgan, trackman; Edgar Boston, bratticeman; Hugh Owens, bratticeman; Henry Hennerty, bratticeman; Harry Thomas, subject.

Primrose colliery, Delano division—Anthony Gludding, captain, pumpman; Joe Maher, pumpman; Daniel Lewis, footman; Daniel Jenkins, driver.

Derringer colliery, Lehigh-Coxe division—Simon Fellin, captain, pumpman; Andrew Bretz, miner; Arthur Michael, helper; Roy Schell, trackman; Clarence Curtier, pumpman.

Centralia colliery, Centralia district—John Wilson, captain, pumpman; Edward Britt, pumpman; Thomas Lamb, footman; Nicholas Willis, bratticeman; Jesse Heist, footman.

Developments in the Export Trade

At the present moment the fate of the export coal trade appears to be hinging on the ability to get vessels at reasonable rates. Further complications are also developing, as, for instance, it is stated that the French government has commandeered all coal carried in French vessels. It is obvious, therefore, that shipments in such boats are not being attempted, except where there is a thorough understanding with the government.

In a press interview, D. J. Wittenberg, President of the Pocohontas and New River Coal Co., predicted last week that American exports to Europe would aggregate one million tons by the first of the year, providing no serious obstacles in transportation or credits arises.

One of the largest deals reported is that said to have been closed by Spanish interests, involving 2,800,000 tons of steam coal. The contract is said to run over a two-year period, and is for delivery at Buenos Aires, Montevideo and Rosario. Loading will be at Philadelphia, Newport News and New York, and the reported price is $2.75 per ton, f.o.b.

At San Francisco, the German steamer "Mazatlan" was held up by the Collector of the Port just as she was about to sail with 500 tons of coal. The coal was contained in sacks, and it was believed that it was destined for the German cruisers "Leipzig" or "Nurnburg."

At Philadelphia, the North German Lloyd steamship "Brandenburg," said to be loaded with 10,000 tons of coal, took out clearance papers for Bergen, Norway, on Aug. 21.

The Hamburg-American steamer "Græcia" cleared from New York on the night of Aug. 27 with 3000 tons of coal for Cadiz, Spain. It is rumored that the coal is destined for the "Kronprinz Wilhelm," which left New York Harbor on the night of Aug. 3 and was last reported in West Indian waters. On the afternoon of Aug. 29, the steamer "Macedonia" of the same line sailed from New Orleans with 5000 tons of coal, in addition to other large supplies. This is the first German vessel to sail from this port since the war was declared. Although ostensibly destined for Cadiz, Spain, it is believed that these supplies are intended for the German cruiser "Dresden."

As regards the foreign situation, the British Government has receded from its demand for a "triple bond" on all export shipments, as was generally expected. This has considerably relieved the tension in foreign markets, particularly in Italy where the situation showed indications of becoming acute. The problem now facing the British exporters, and also those in this country, has resolved itself into one of financing. It would seem that the different governments might advantageously arrange to guarantee payments by responsible purchasers.

Reports from England are of a rather conflicting nature, it being noted on one hand that the government has requested the collieries to work on Sunday, while on the other hand, it is stated that there are enormous supplies at all the shipping points because of the almost complete suspension of industrial demand. The only serious difficulty the British operators now seem to be facing is in transportation lines. The heavy burden thrown upon the railroads of the country in moving the troops and muntions of war has so congested the service, that trouble is being experienced in this line.

Recent issues of the *Daily Consular and Trade Reports* contain the following notes relative to the export trade and foreign mining conditions.

South America—A telegram from an American consular officer in a South American country stated that the Government railways want 300,000 tons of coal annually for three years. Particulars are being forwarded by the first mail from the consulate.—No. 13583.

Europe—An American consul reports that two coal merchants in a European country desire to receive offers from American coal exporters and also some publications on the trade. Correspondence should be in French, and copies should be sent to the consulate submitting the report.—No. 13572.

Discussion By Readers

The Flame of a Mine Explosion

In connection with the many experiments made to determine the correct explanation of the phenomena observed at the mouth of a mine, at the moment of explosion, COAL AGE, Aug. 22, p. 295, the following incident illustrating the wonderful expansive force of the flame of an explosion, on reaching the open air, will prove of interest:

The Palos mine explosion occurred May 5, 1910, at Palos, Ala. In this mine, the main-slope heading was quite contracted. The narrowest place in the heading had an area of less than 27 sq.ft. The gases and dust projected from this small opening at the moment of the explosion, took fire in the air and the flames spread on each side of the mouth of the mine, to a distance of over 80 ft., burning and scorching the leaves on the trees and bushes in that area. Wood was charred at a distance of 105 ft. from the mouth of the mine, in the direction of the axis of the slope, and a mail carrier was killed some 70 or 80 ft. away from the mine entrance. He was burned worse than any other man killed in that explosion. Had it not been for a heavy railroad trestle, in its path, the flame would have reached a still greater distance.

The sight was witnessed by a number of men, who stated that the flames leaped upward to a distance claimed to be anywhere from 200 to 500 ft. in height. I mention this incident as showing how the flames of an explosion would spread in a mine where the air conditions are in its favor.

Republic, Ala.

A "Mine-Run" Failure

The fact that the mine-run law, recently enacted in Ohio, is a failure, at least in the No. 8 seam, is proven quite conclusively by the statement of eastern Ohio operators, to the effect that the shutdown of the Block House mine of the Dexter Coal Co., a branch of the Pittsburgh-Buffalo Coal Co., was necessary owing to the high cost of production.

An investigation of the cost of operating this mine showed that the coal mined on a run-of-mine basis was being produced at an increase of 16c. above the price prevailing the preceding year. The giving out of this information has caused much comment in mining circles, since the fact was well known that the court was desirous that this mine should continue in operation. Since they began operating on the run-of-mine basis, the company have had constant complaints in regard to the preparation of the coal, which is another feature requiring careful consideration. When it was finally found impossible to reduce the cost of production so that it would more nearly approximate that of the previous year, it was decided to close down the mine, since, to continue in operation, was merely piling up debts for the already embarrassed company.

The suspension of the Block House mine has set everyone interested in the success of the coal-mining industry in the state, to thinking seriously over the various developments and conditions following in the wake of the strike. The utter uselessness of the operators in the No. 8 seam, attempting to operate on a mine-run basis is apparent to everyone.

This feeling is growing stronger every day; and it would not be surprising if, as is indeed already rumored, a large class of miners will soon be endeavoring to arrange conferences with the operators, for the purpose of negotiating a contract under a wage scale that will permit the operators to run their mines on the same basis as last year. This would seem to be the only practical solution of the problem. The instance to which I have referred, namely, the shutting down of the Block House mine, is only an example where the new system has been given a thorough trial and been found wanting.

O. P. RATER.

————, Ohio.

Keeping Rooms on Sights

I was pleased to see the inquiry in regard to driving rooms on sights, COAL AGE, Aug. 22, p. 317. About a year or so ago, we were having much trouble, in the mine, with the rooms "holing" into each other, due to the carelessness of the "cutters" or machine runners.

Our rooms are turned off at right angles to the butts and driven on the face of the coal. The rooms are driven on 50-ft. centers and are 28 ft. wide, leaving a "rib" (room pillar) 22 ft. wide. The rooms are driven up anywhere from 200 to 300 ft. and a chain pillar 40 ft. wide is left along the entry. It was a common everyday occurrence to find an unexpected breakthrough at the face of a room.

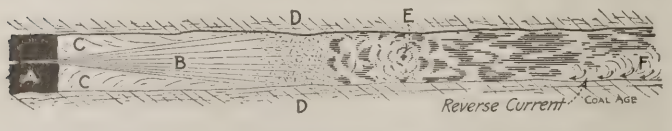
Having a compass at the mine, and both the mine foreman and myself being able to set sights, we decided to try out the method of driving all rooms on sights. This was not a difficult matter, after we had once caught up with the men; but, as our friend from Kentucky states, the sights were often disregarded, and we found it a difficult matter to get the men to pay proper attention to them.

However, after a few of the careless ones had a week or so off, and the loaders were forced to take a "skip," which was always pickwork, at loading price, they began to sit up and take notice of the "sights." I am pleased to say that, at the present time, we are having no trouble of this kind, and the "holing" of rooms into each other is a thing of the past. The ribs in the rooms will scarcely vary 2 ft. their entire length. There is, of course, an occasional error in setting the sights; but this is generally soon detected before it causes any trouble.

The process is as follows: When a room has been "necked" and as soon as the first three cuts are taken

out, before the switch is laid, we set up the compass and put in a pair of sights on the course the room is to be driven. All sights are placed on the same side of the room, about 4 ft. from the ribs. The neck is driven narrow for about 60 ft. Then, the cutter drops back about 20 ft. from the face and widens the place on the opposite side from the sights.

It is sometimes claimed that carrying rooms on sights is a hard matter, but this is not my experience. A good entryman will drive his entry from one station to another and will scarcely vary a foot, in going 300 or 400 ft. by the sights set by the engineer. If this can be done in the entries, why not in driving rooms.



Before a machine is taken to the face of the room, the cutter will generally send his helper up to the face to see that it is in proper condition. If all is ready, the helper is instructed to hold his lamp at the face, and the cutter lines him in by the sights in the neck of the room. This being done, an arrow is marked on the roof with a piece of chalk. This shows the cutter, at a glance, whether the rib is to be gripped or set back.

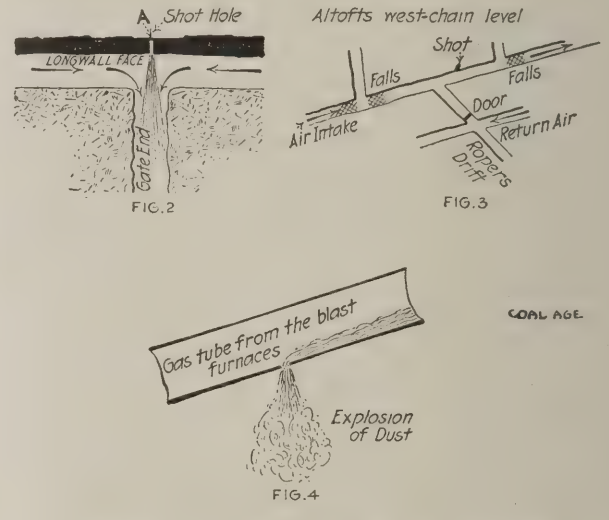
Pine Run Co.
Vandergrift, Penn.

The Verner Theory

Referring to the editorial on this subject, COAL AGE, Aug. 15, p. 273, I notice the statement that the "theory about the counter air current in a mine explosion has gradually gained strength." In a previous letter, I asked Mr. Verner to explain his theory of the counter-current by means of diagrams. He did not do this, however, but Mr. Parfitt came to the rescue with an explanation of the phenomenon, illustrating it by means of a sketch, COAL AGE, Vol. 5, p. 1059.

Referring to this sketch, Fig. 1, Mr. Parfitt assumed that the so called "reverse current" started at a point marked *F* in the figure. It is clear, however, that no such reverse current could be produced until the force exerted by the powder or other explosive had expended its



IDEAL SKETCH, ILLUSTRATING THE INITIATION OF A MINE EXPLOSION

energy. It would also seem that, at the point marked *C* in the figure, the air would be in a state of compression instead of a "depression or vacuous condition" existing, as he stated, assuming the shot was fired in the face of a heading. There might be a suction effect or depression if such a shot were to be fired at a gate-end, on a longwall face. I have tried to illustrate this suction effect, in Fig. 2. Here the firing of the shot *A*, at the gate-end would naturally draw air from the face on each side of the shot, as shown by the small arrows in the figure after the principle of an injector.

From Mr. Parfitt's illustration, Fig. 1, it might be assumed that the reverse current *F* resulted from the cooling of the heated gases from the blownout shot; but, here, the explanation is dropped. Mr. Verner would have done well to have taken up the explanation at this point and showed what followed the starting of the reverse current at the point *F*.

In my opinion the presentation of any theory should be accompanied by sketches or diagrams to make the intended meaning clear; and should be further supported by references to actual occurrences, as far as possible. In differing with Mr. Verner, in reference to his theory of the reverse current being a factor in the initiation of a mine explosion, I shall endeavor to explain my ideas by reference to observed occurrences, and to illustrate these by brief sketches that will assist the understanding.

ILLUSTRATING MINE-EXPLOSION THEORIES

In practically every mine disaster with which I have had an intimate acquaintance and which was caused by the firing of a shot, I have observed that there was invariably a large cavity or air space in the immediate neighborhood of the blast. Again, I have observed another important feature of such disasters, namely, there is always a considerable area, in the immediate neighborhood of the blast, in which there is little or no evidence of damage having been done such as is plainly observable at a distance more removed from the initial point where the shot was exploded.

Referring now to a case in point, namely, the Altofts explosion, Fig. 3 shows approximately the position of the shot that was the primary cause of this disaster. The shot was drilled in such a direction, in the rib of the west-chain-haulage road, that when it blew out, the heated gases and solid matter were projected *against the air current,* which is shown in the figure by the small arrows. In this case, the nearest large air space was the heading known as "Roper's drift." It was observed, in this explosion, that the men who were killed had taken warning that all was not right and had moved from the manholes where they had gone for shelter. The distance these men moved from their position when the shot exploded, indicates a certain lapse or interval of time between the blowing out of the shot and the second blast or explosion, which killed them instantly. A similar interval of time has been observed on other like occasions, where men have been warned of the danger and sought to escape, but were killed instantly by a second blast. In the Altofts mine, there was little or no damage done, for a distance of about 75 yd. on either side of the shot.

My opinion, based on these facts, is that when a shot blows out, the heated gases and particles of solid matter are projected into the mine roadway where the blast stirs up the dust. At this initial moment, the immediate atmosphere in the vicinity of the shot is quickly rendered devoid of oxygen, which makes an explosion of the dust and gases at this point impossible. I believe the interval of time that intervenes until the expanding and projected gases meet with a sufficient volume of air for their explosive combustion, is the brief period in which the later victims of the explosion attempt to escape and move from their places for that purpose. The real explosion that wrecks the mine, I consider, is that which occurs when these heated gases and dust encounter sufficient air for their combustion.

In support of this conclusion, I want to refer to an incident observed when passing through a blast-furnace ironworks, on an idle day when the men were cleaning out the gas mains connecting the tops of the furnaces with the battery of boilers. In doing this work, the dust and soot accumulated in the mains were scraped to the handholes in the bottom of the tubes (Fig. 4). The men had taken the precaution to dampen the dust inside the tube and never to open a handhole in advance of the portion of the tube that was being scraped. The reason for this was quickly evident after observing what took place when the heated dust fell through the handhole into the air below. A dense black cloud of dust would fall for a considerable distance and then burst into a violent flame or explosion. This, to my mind, is a simple illustration of what happens in a mine when a blownout or windy shot is the cause of an explosion such as that at Altofts.

Unless I wholly misunderstand Mr. Verner, he is at a complete loss to show where his reverse air current would assist in explaining the Altofts disaster, or the explosion of the dust as observed at the ironworks, just mentioned. Neither Mr. Verner nor Mr. Parfitt has shown any reverse current other than that due to the cooling of the heated gases, which occurs in what is properly called the "condensation stage" common to every mine explosion and which is nothing new in respect to such occurrences.

In closing, permit me to say that, whatever new points may be raised in connection with this theory, it has not yet been shown what influence the reverse current can exert at the initial point of an explosion. What follows this is not pertinent to the question. Therefore, what Mr. Verner has called the "counter air current" is still without any clearly defined explanation.

JAMES ASHWORTH,
Mining Engineer.

Vancouver, B. C., Canada.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

PLAN OF MINE

General Requirements—In the planning of a coal mine the most careful consideration must be given to the questions of **ventilation, drainage** and **haulage,** as these arrangements, to a great degree, determine the successful operation of the mine.

In order to insure the safe and economic extraction of the coal, the same careful consideration must be given to ascertaining the extent and character of the seam, its depth below the surface, inclination and thickness, the character of the roof and floor and the hardness of the coal, its cleavages and faults, impurities, etc.

The information thus gained will be of the first importance in deciding on the most suitable method of mining to adopt, in order to secure the largest returns on the investment, the most complete extraction of the coal and the greatest safety in mining the same.

Economy and Efficiency—The **economic ventilation** of a mine premises the circulation of the required air volume, with the least expenditure of power. **Efficient ventilation** requires the circulation and proportionate distribution in the mine workings, of such a volume of air as will not only meet the requirements of the law; but, likewise, produce the necessary velocity in all roads and passageways and at the working faces of all headings and chambers, so as to sweep away the smoke and gases that would otherwise accumulate therein; and to so ventilate all waste, void and abandoned places as to prevent them from becoming a menace to the safety of the mine as reservoirs for the accumulation of gas.

The Main Airways—While two airways, an intake and a return airway of sufficient size, furnish the necessary means for conducting the air current to and from the working faces of the mine, there are other considerations of economy and safety of operation that demand a larger number of main airways.

The **number** of main airways required, in any case, is determined by their size and the necessary volume of air that must pass through them. The limiting factor in this calculation is the safe and economic **velocity** of the air current traveling the main airways.

While too low a velocity of the air is dangerous because of its failure to remove the accumulating gases, too high a velocity, on the other hand, is dangerous by reason of its increasing explosive conditions in the mine air, by raising and carrying in suspension fine dust, and by furnishing an excessive supply of oxygen that invites active and explosive combustion.

The velocity of main air currents in mines can safely vary between 250 and 1200 ft. per min.; and for short distances a velocity of 2000 ft. per min. may be permitted, although high velocities rapidly increase the power producing the circulation. Where the main intake airways are used for haulage roads, it will not be possible or advisable to employ a velocity much exceeding 400 or 500 ft. per min., owing to the annoyance and danger of drivers losing their lights.

The Coal Age Pocket Book

Illustration—In the planning of a mine for an output of, say 2000 tons of coal per working day, in a 6-ft. seam of more or less inflammable bituminous coal (shaft, slope or drift openings), the following data may be assumed as approximating possible conditions, but modified to suit known facts that have been determined, in special cases:

Output per man per day (average)	2½ tons
Number of miners employed (2000 ÷ 2.5)	800
Number of loaders or helpers	400
Number of drivers, trackmen, timbermen, etc.	60
Foreman, assistant foremen and firebosses	20
Total number of men and boys	1280
Number of mules	25

Assuming a gaseous mine requiring, by law, say 150 cu.ft. of air per man, and 600 cu.ft. per mule, per minute, the necessary circulation based on these data would be (1280 × 150) + (25 × 600) = 207,000 cu.ft. per min.; or, to allow for certain leakage, say the necessary air volume is, in this case, 225,000 cu.ft. per min.

Driving 10-ft. openings in a 6-ft. seam and allowing for necessary timbering would leave an unobstructed effective area of, say 50 sq.ft. In this case adopting a 4-entry system for the intake and the same for the return, would give for the total effective intake and return areas, each 4 × 50 = 200 sq.ft., which would make the velocity of the intake air current 225,000 ÷ 200 = 1125 ft. per min., which is a safe and economical velocity, provided these airways are not used as haulage roads.

To provide for the expansion of the return air, owing to rise of temperature and addition of mine gases, which may altogether amount to 6 or 8 per cent., the return airways should be driven, say 8 or 10 in. wider than the intake airways.

Economy of Multiple Main Airways—The economy of driving a multiple system of main airways will not be questioned in the planning of large operations. The same plan should be applied to the opening of mines on a smaller scale, the objective point being to keep the velocity of the main air current so that it will not exceed 1200 ft. per min., for any considerable distance.

The saving in power (fuel consumption, equipment and attendance) will pay for the increased expense of upkeep of entries; and the system affords a large increase in safety by reducing explosive conditions and providing additional avenues of escape in case of accident. There is afforded, besides, room for a double-track haulage system, which will prove a great advantage in the operation of the mine.

Assuming that one-half the power on the air is consumed in the main airways, which more or less closely approximates the fact, and taking the general efficiency of the fan and engine as 60 per cent., a double-entry system, for the main intake and return airways, would effect a saving in fuel of 11.25 per cent.; a triple-entry system, 13.32 per cent., and a 4-entry system, 14.10 per cent.

Inquiries of General Interest

Ventilation Question

The following question, which was asked at a mine inspector's examination held at Pittsburgh, May, 1909, has recently aroused considerable discussion as to its correct answer. We would very much appreciate seeing this question answered in the columns of COAL AGE. It is as follows:

A total of 8000 cu.ft. of air passes through three airways, *A*, *B* and *C*, under a water gage of 1.7 in. All the airways have the same sectional area and their lengths are as follows: *A*, 6000 ft.; *B*, 10,000 ft.; and *C*, 21,000 ft. It is desired to increase the quantities of air passing in the airways *B* and *C*, so that all three airways shall pass the same quantity of air (in other words, the main air current is to be equally divided between the three airways).

(a) What effect will this change have on the water gage? (b) How much will the resistance be increased in *A* and *B* when the change is made? (c) If the airways *B* and *C* were to receive as much air as the airway *A* gets now, what would be the total quantity of air in circulation?

A correct answer to this question will be greatly appreciated by a number of COAL AGE readers.

CHARTER SUBSCRIBER.

Pittsburgh, Penn.

The question is, to a certain extent, incomplete, inasmuch as it does not state that the power on the air remains constant, which is the natural assumption to make, although the conditions in (c) clearly demand an increase of power.

Evidently, the first step in the solution is to determine which of the three airways will be the free or open split, requiring no regulator in the proposed redistribution of the air. This can be found by calculating the relative pressure potentials for the three airways, respectively. Thus,

Split *A*, $X_a = \frac{1}{\sqrt{l}} = \frac{1}{\sqrt{6}} = 0.4082$

Split *B*, $X_b = \frac{1}{\sqrt{10}} = 0.3172$

Split *C*, $X_c = \frac{1}{\sqrt{21}} = 0.2182$

$\Sigma X_p \ldots\ldots\ldots 0.9426$

The airway having the smallest potential value is the one that naturally takes the smallest quantity of air, and is therefore the one having the greatest resisting power; which fact makes it the free or open split, in the redistribution of the air. In the present case, split *C* is the open split, while regulators must be placed in the other airways, *A* and *B*.

In splitting, the pressure is the same for all the splits; and in this case, the pressure and quantity of air being the same for each split, the power on the air will be equally divided between them because the power is equal to the product of these two factors. The next step, therefore, is to find the original power on the air, which is assumed to remain constant after the change. Thus,

$U = Q\,p = 8000\ (5.2 \times 1.7) = 70{,}720$ *ft.-lb. per min.*

The simplest method of solution, now, is to find the quantity of air and the power, for split *C*, before the change was made; and, then, since each split absorbs one-third of the original power on the air, find the quantity of air that will pass in the open split *C*, according to the rule that the quantity of air circulating in an open airway varies as the cube root of the power. The water gage is then found, according to the rule that the water gage varies as the square of the quantity of air in circulation.

The quantity of air in circulation in an open airway being proportional to the pressure potential for that airway, the quantity for split *C* (natural division) before the change, is

$$q_{c_1} = \frac{0.2182}{0.9426} \times 8000 = 1852\ \textit{cu.ft. per min.}$$

But, the pressure being the same for all the splits, the power on the air for split *C* is proportional to the quantity of air passing in that split; thus,

$$u_{c_1} = \frac{1852}{8000} \times 70{,}720 = 16{,}371\ \textit{ft.-lb. per min.}$$

Since, after the change is made, split *C* absorbs one-third of the original power, it then consumes $70{,}720 \div 3 = 23{,}573$ ft.-lb. per min. Then the quantity of air passing in this split, which is open, having no regulator, is

$$q_{c_2} = 1852 \sqrt[3]{\frac{23{,}573}{70{,}720}} = 2091\ \textit{cu.ft. per min.}$$

(a) Since the pressure or water gage is proportional to the square of the quantity of air passing, the water gage, after placing the regulators for an equal distribution of the air, is

$$w.g._2 = 1.7 \left(\frac{2091}{1852}\right)^2 = 2.167\ \textit{in.}$$

(b) For the same sectional area of an airway, the resistance is proportional to the pressure or water gage; and is, in this case,

$$\frac{R_2}{R_1} = \frac{2.167}{1.7} = 1.274\ \textit{times}$$

(c) The quantity of air that was passing in split *A* before the change was made, is

$$q_{a_1} = \frac{0.4082}{0.9426} \times 8000 = 3464\ \textit{cu.ft. per min.}$$

If airways *B* and *C* each get this amount of air, the total circulation will be $3 \times 3464 = 10{,}392$ cu.ft. per min. This, however, would require a large increase of power. Assuming a constant power, as previously, the total circulation after the change is $3 \times 2091 = 6273$ cu.ft. per min.

Examination Questions

British Columbia Examination, May 20, 1914

(*Selected Questions*)

VENTILATION

Ques.—How many cubic feet of air is traveling in an air course which is 8½ ft. wide at the bottom, 7½ ft. wide at the top and 5½ ft. high, when the anemometer shows a reading of 85 revolutions?

Ans.—The average width of the airway is ½ (7½ + 8½) = 8 ft. and the sectional area is, therefore, 8 × 5½ = 44 sq.ft. Then, assuming the anemometer reading is 85 r.p.m., the quantity of air in circulation in this airway is 85 × 44 = 3740 cu.ft. per min. In this answer, no allowance is made for correction of the reading of the instrument, for the reason that the measurement of the velocity of an air current in this manner is only approximate at the best; and, in ordinary practice, this correction is neglected.

Ques.—If, by applying 42,000 units of work, you obtain 31,500 cu.ft. of air per min., what units of work will be required to produce 70,000 cu.ft. per min.?

Ans.—For the same airway, the power or units of work applied to the air varies as the cube of the quantity of air in circulation. In other words, the power ratio is equal to the cube of the quantity ratio, which gives, in this case,

$$\frac{x}{42{,}000} = \left(\frac{70{,}000}{31{,}500}\right)^3 = 460{,}900 \textit{ ft.-lb. per min.}$$

Ques.—Explain the principle of natural ventilation.

Ans.—The principle of natural ventilation depends upon the difference in the density of two air columns that would otherwise be in equilibrium; or, upon any dynamic force, such as wind pressure or the pressure of escaping steam that would give motion to the air in an airway or air conduit. The difference in the density of air columns may arise from a difference in temperature, the warmer air being lighter than air of a lower temperature, volume for volume; or the difference in density may be due to the presence of a considerable quantity of gases that are either lighter or heavier than atmospheric air.

A difference in density causes the heavier of the two columns to sink, by reason of its greater weight, the lighter air column being thereby forced upward. These air columns may exist in a mine shaft or slope or in dip or rise workings in the mine. The result is always a more or less rapid movement of the air from the point of higher pressure toward the point of lower pressure, the movement being due to the natural causes just mentioned.

Ques.—Explain the difference in the methods of producing an air current by a forced fan and by an exhaust fan.

Ans.—As far as the fan itself is concerned, the action is the same in both cases. The revolution of the air within the fan gives to it a centrifugal force that causes it to move from the center toward the circumference of the fan. It is this movement of the air within the fan that results in a depression at the central opening and a compression at the circumference or the discharge opening of the fan.

In the case of a forced fan, the fan drift is connected directly with the circumference and receives the air discharged by the fan, which air is conducted into the mine. Owing to the resulting depression at the central opening of the fan, the atmospheric air enters the fan at this point. In the case of an exhaust fan, the fan drift is placed in connection with the central opening of the fan, which therefore draws the air from the mine and discharges it into the atmosphere at the circumference through the fan chimney.

Ques.—When the barometer reads 23.2 in., what is the pressure of the atmosphere (a) per sq.in.; (b) per sq.ft.?

Ans.—(a) Since 1 cu.in. of mercury weighs 0.491 lb., the atmospheric pressure corresponding to a barometer reading of 23.2 in. is 23.2 × 0.491 = 11.39 lb. per sq.in. (b) This corresponds to a pressure of 11.39 × 144 = 1640+ lb. per sq.ft.

Ques.—In order to secure thorough ventilation in a mine, about what velocity should the current have at the face of the workings, both in gaseous and nongaseous mines?

Ans.—The thorough ventilation of a mine at the working face requires a velocity sufficient for the removal of the gases that would otherwise accumulate. In a nongaseous mine, for the convenience of the men, the velocity of the air current should not exceed 3 or 4 ft. a second, say 200 ft. a minute. At times, a less velocity than this is desirable. In a gaseous mine, assuming the air current is properly deflected by means of brattices, so as to sweep the face of the coal, a velocity varying from 240 to 360 ft. per min. should be sufficient for the removal of the gases, except in special cases in rise or dip workings that often render the efficient ventilation of the working face difficult.

The removal of marsh gas from the face of rise workings or carbon dioxide from the face of dip workings may frequently require a higher velocity of the air current. Under these conditions, proper precaution must be taken not to expose the safety lamps of the miners to the full force of the current, which may have a velocity of 600 ft. per min.

Ques.—How can you tell whether or not any obstruction is in an air course that you have not passed through?

Ans.—Any obstruction in an air course would be indicated by the decreased velocity and quantity of air in circulation and by an increase of water gage for that airway. A decrease in the quantity of air passing, together with a like decrease in the water gage would point to trouble outside of the airways in question, by reason of which the quantity of air supplied to that section has fallen below the normal quantity. Under a normal condition of the general ventilating system in the mine, an obstruction in any section or district of the mine will cause a decrease in the quantity of air passing and an increase of the water gage for that section.

Coal and Coke News

Pennsylvania

Anthracite

Wilkes-Barre—With a view of insuring protection to surface property from mine caves, the Lehigh & Wilkes-Barre Coal Co. has requested the city of Wilkes-Barre to permit the driving of bore holes in the Heights section, the object being to ascertain how near the coal is to the surface, so that proper steps can be taken to safeguard property. Believing that the action of the company will enable the city to protect the section in question from the danger of mine caves, a resolution has been introduced in the City Council authorizing the company to drive the bore holes, but requires it to furnish the city with a copy of the results of the tests.

Harrisburg—Fifty anthracite coal companies have filed appeals from the amount of the anthracite coal tax assessed against them under the act of 1913, in the Dauphin County Court, and probably 100 companies have taken the matter to court. The auditor-general's department went ahead with its making out of bills for the amount of the tax based on the reports of the anthracite producers made on their output last year, some weeks ago. The test of the constitutionality of the tax brought in the Dauphin County Court by the People's Coal Co., of Scranton, in which a dozen or more companies joined, has not been decided, and the companies have determined to take the settlements into court, pending the decision on the case. Thus far but two coal companies have paid, and one of them under protest, so that it may be months before the coal tax is settled. No matter which way the case is decided in the Dauphin County Courts, it will be appealed to the Supreme Court.

Pottsville—Mining men have called attention to a possible shortage in the supply of dynamite, caused by the failure of manufacturers to secure raw glycerine, dynamite's chief ingredient, which is produced in Europe. Since the opening of the war, the price of glycerine has increased 100 per cent., and it is not improbable that traffic in the product may stop until the war has ended.

Peckville—Residents of Blakely Borough are somewhat incensed over the fact that culm is allowed to run in pipes from the breakers of the Mt. Jessup Coal Co. to the Lackawanna River, thus polluting the waters of this stream.

Pittston—After several days of waiting, the expected mine cave at the intersection of William and Ford Sts. occurred at noon, on Aug. 24. This settlement took down 40 sq.ft. of brick pavement, together with the track of the Scranton Traction Co. The sewer and water pipes were also damaged.

Reading—The anthracite market is becoming more active and inquiries are plentiful. The mines of the Philadelphia & Reading Coal & Iron Co., which have been working for three days per week for some time past, are now working five days per week. There is an improvement in the demand for all sizes, and the indications point to a busy fall and winter.

Bituminous

Greensburg—Coal operators in this vicinity are making plans for one of the biggest booms ever experienced in the coal business in this part of the state. According to some of the leading operators, the closing down of the Welsh, German and Belgian mines has created a fuel shortage in Europe that threatens to tie up the industry in neutral countries all over the world. Steamships are seriously affected. The coal operators say they are only waiting for the Federal Government to provide the means of shipping coal to start one of the greatest periods of prosperity in the coal industry in this section.

Johnstown—The much discussed Boswell cut-off of the Baltimore & Ohio R.R. to Johnstown is said to have been suddenly projected into the region of probability. Several representatives have been sent to the vicinity of the proposed right-of-way to investigate conditions, it is said. The proposed line would give the Baltimore & Ohio access to a rich virgin coal field, besides creating an additional rail line out of the city to the south. The developments of coal lands in that vicinity is only a matter of a few years, according to coal experts, as borings have established the presence of rich beds of coal.

Pittsburgh—Because the breadwinners of the family have in many instances returned to Europe, the poor directors of western Pennsylvania counties are being besieged with applications for aid from destitute foreign families. Throughout the coke regions, the task of providing these people with food is becoming acute. The foreign populaaion is here large, and many of the men returned to their home countries before hostilities began.

WEST VIRGINIA

Charleston—Miners who have been on strike at Boomer, Winifrede and Black Betsy have returned to work, under an agreement by which operations will be kept up pending the negotiations now on between the union and the Kanawha Coal Operators' Association. The trouble at these points rests principally on the discharge of miners by the superintendents, for various reasons, and the negotiations are now being conducted with reference to a clause in the three-year agreement specified reserving to employers full right to hire and discharge men. The point is to be settled, it is understood, by an umpire selected by the two boards.

Fayetteville—Several hundred men employed by the Paint Creek Co. in its operations in seven mines on Paint and Brier Creeks have been idle for several days, following the failure of the company to pay them at the usual time. This is said to have occurred before at the company's mines, and the men refuse to go back to work until they are paid. The mines affected are those at Mucklow, Wacoma, Banner, Tomsburg, Hickory Camp and Brier Creek.

Dorothy—The two mines of the Four States Coal Co., located on Coal Creek, near this place, have been closed down for an indefinite period, on account of the inability of the company to arrive at a satisfactory agreement with the miners. About 600 men are affected. There has been trouble at the mine for several weeks, conferences failing to evolve a settlement.

ALABAMA

Gadsden—The Van Zandt Mine No. 2 of the Racoon Mining Co., near Gadsden, Ala., after having been closed down for the past year, has resumed operations. G. T. Schoolar, of Gadsden, is president.

Cullman—The Soutts Mountain Coal & Coke Co., which has been operating on an extensive scale near Cullman, Ala., for the past 15 years, having worked out its territory, has sold its stock and closed down. Robert Stephens, of Birmingham, is president.

Cordova—Sale of the properties of the Oakleaf Coal Co. will be transacted privately, as the auction sale was unsuccessful. This is the order of E. H. Dryer, referee in bankruptcy.

TENNESSEE

Knoxville—A miners' field day will be held in Knoxville, on or about Oct. 15, according to officials in charge of the local mine-rescue station. First-aid, explosion demonstrations and athletic contests will feature the occasion. Elaborate preparations are being made, and it is expected that miners from all over the South will attend.

Jellico—After a day's conference at Jellico, the three Knoxville officers of the United Mine Workers of America and operators in the Jellico district agreed to postpone discussion of the wage scale until Sept. 18. It was stated that the miners officers are preparing a petition for presentation to the Tennessee Legislature at the next session requesting the removal of convicts from the mines of the state.

KENTUCKY

Barbourville—Continued improvement in the coal industry is leading to a full resumption of operations in the southeastern Kentucky fields. In the event of a prolonged European war, local operators believe that they can supply a great part of the Eastern trade, which draws its present supply from the Eastern States.

London—The office and store building of the New Laurel Coal Co., at Pittsburg, Ky., two miles south of here; the office of Captain W. A. Pugh, coal operator, and other structures were destroyed recently by fire. The total loss is estimated at $10,000, only partly covered by insurance.

Jenkins—It is said the Consolidation Coal Co., in its Jenkins-McRoberts coal field, is making increases in its plants and will double its capacity within the next 30 days. Railroads—both the Louisville & Nashville and the Baltimore & Ohio—are taxed to their limit to handle the large tonnage. Additional trains will be added.

Mater—The Elkhorn Coal Co. will make increases in its plant here soon. One hundred extra miners will be put to work; 200 houses are under construction.

OHIO

Coshocton—After a session covering two weeks, with frequent interludes for private conference, the joint meeting of Ohio miners and operators interested in the strike in this part of the field adjourned on the afternoon of Aug. 29 without having come to any settlement. A thousand miners will continue on strike in consequence, unless some means of ending the trouble is quickly arrived at.

Congo—Mine No. 301, at this place, which was badly damaged by fire on Oct. 31 of last year, has been inspected by representatives of the State Mining Department and found to be in shape for the resumption of work, as the fire has been completely smothered. It is expected that it will again be in operation by the middle of September.

INDIANA

Terre Haute—Officials of the United States Bureau of Mines have been here arranging for the contests, Sept. 12, when teams and individuals will do first-aid and rescue work and the bureau will give demonstrations of explosions with its steel room. Teams are being entered from the Eastern fields, and following the contests a training school will be established in this city.

ILLINOIS

Peoria—The Ubben Coal Co. is making arrangements for considerable improvements at its mine on the East Bluff. The installation of electric mining machinery will be one of the changes made, and the interior of the mine is to be lighted electrically.

Danville—Local coal operators recently received announcements of the National First-Aid and Rescue Meet to be held in Terre Haute, Ind., Sept. 12. The Bunsen Coal Co. will have teams entered from both the Westville and Universal (Indiana) districts, and it is believed that these contestants will make a creditable showing.

Herrin—The Roberts & Schaefer Co., of Chicago, which has the contract to rebuild the top works, recently destroyed by fire at Mine B of the Chicago & Carterville Coal Co., is breaking records in getting the property in shape for operation. It is expected that within 30 days from the time the contract was awarded, the property will be in shape to hoist coal.

Marion—The drouth in the southern Illinois mining fields was broken during the past week by several days of heavy rain. In many sections, this is the first rain since last May, and since as early as June, water has had to be hauled to several mines to keep them in operation. The supply is now abundant.

MISSOURI

Kansas City—The district conferences that have been in session for several months have been concluded. Satisfactory settlements have been made in all districts where there have been dissensions between operators and miners, and all the mines are running full crews.

Webb City—For the first time, the mine-rescue car of the National Bureau of Mines, which heretofore has confined its demonstration and lecture work to coal-mining districts, has been sent to a metal-mining section. It is now stationed here, and will remain in this vicinity a month. Its presence is due to the activities of the Jasper County Anti-Tuberculosis Society, which was organized after attention had been called to the high death rate from tuberculosis in the mines. The car is later to be taken to Fort Smith, Ark.

COLORADO

Denver—Thirty-five independent Colorado coal operators on Aug. 29 signed working agreements for the coming year with the district organization of the United Mine Workers of America. All these operators who have conducted their properties during the last few months under agreements with the Union renewed these agreements, the old contracts expiring Sept. 1. Two thousand men are employed in the independent coal mines.

Hayden—The Colorado-Utah Fuel Co. is sinking a large coal mine on what is known as the Wedge seam, in the middle series, and building a large camp, at Harris, near Hayden, Routt County, Colo., on the Denver & Salt Lake R.R. The vein at this point is slightly pitching and shows from 7 to 9 ft. of high-grade bituminous coal, and will be worked by a rock slope about 150 ft. long, which has recently reached the coal. Shipping is expected to begin in about 30 days, and in about a year to reach an output of 2000 tons per day.

WYOMING

Kemmerer—Mine No. 6 of the Kemmerer Coal Co., which was shut down last Spring, has been reopened and will employ 150 men.

MONTANA

Lombard—The Western Coal & Coke Co., owning a valuable coking coal property near Lombard, Mont., on the Northern Pacific Ry., is selling an issue of $150,000 of preferred stock for the purpose of opening a small mine and erecting a coal washer, small battery or byproduct coke ovens, probably of the Mueller type, a few dwelling houses and other equipment necesary for such a plant. Construction work is expected to begin in the early coming spring.

FOREIGN NEWS

Paris, France—Refugees from Frameries, Belgium, declare that when the Germans occupied that town, they stopped all mine shafts and destroyed the machinery. Some go so far as to say that many miners were at work in the mines when the pit mouths were closed. This is, however, hardly probable.

PERSONALS

Edward H. Coxe, of La Folette, Tenn., has just returned from a three weeks' trip to Denver and the Routt County coal fields.

Samuel D. Weakley has been retained by the Alabama Coal Operators' Association to conduct the resistance to the plan of the railroads to make an increase in local coal rates.

W. T. Brown, of Ragland, Ala., has reopened his mines at Taits Gap, the same having been closed down for more than a year. Extensive improvements have just been completed.

Sam Davis, the well known Toledo coal dealer, has a force of men at work on what it is said will be when completed the largest coal yards in Ohio. The initial outlay on the new coal yards will be $30,000.

Kenneth U. Meguire, of Louisville, Ky., president of the Harlan Coal Co. and of the Snead-Meguire Coal Co., recently went to Fairmount, W. Va., to play golf with George T. and James O. Watson in the tournament in which the three coal men are all entered.

George G. Yeomans, formerly assistant to President Delano, of the Wabash R.R. Co., has been elected president of the Monon Coal Co., of Indiana, with headquarters in the Old Colony Building, Chicago. This position was recently vacated by Harry N. Taylor, of Chicago.

William McLaughlin, of Huntington, Ark., was recently elected president, succeeding Peter R. Steward, of McAllister, Okla., resigned, of the United Mine Workers of America of Oklahoma, Arkansas and Texas. Thomas L. King, of Fort Smith, Ark., was elected vice-president.

Thomas E. Byrnes, of St. Louis, Mo., for several years with the Franklin Coal & Coke Co., and the Bickett Coal & Coke Co., and formerly superintendent of transportation of the Missouri Pacific-Iron Mountain Lines, entered the coal business for himself on Sept. 1, with offices in the Wright Building.

John Britt, chief of the mine clerks of the Pittsburgh Coal Co., of Pittsburgh, Penn., has retired from that organization to become identified with the Berwind-White Coal Mining Co., at Windber, Penn., as auditor of the latter company. Mr. Britt has been succeeded by W. C. Fife, of the operating department of the Pittsburgh Coal Co.

Colonel Harvey M. La Follette, formerly president of the La Follette Coal, Iron & Ry. Co., returned last week to La Follette, Tenn., after a protracted absence in New York, where he has been working on a plan to reorganize the above mentioned company, now in the hands of a receiver. After remaining in La Follette a few days, he returned to New York to again take up his reorganization work.

OBITUARY

Thomas B. Heims, formerly a bituminous coal operator at Osceola Mills, Penn., died recently at his home in Philadelphia. He was 64 years of age and retired from business three years ago.

W. C. Lovejoy, aged 36 years, a well known coal man of Birmingham, secretary of the Canal-Export Coal Co., committed suicide at St. Vincent's Hospital, Birmingham, on Aug. 25. Ill health is said to have been the cause.

John Ralston, 84 years old, a pioneer operator of the Middlesboro, Ky., district, and the first inspector sent into this section by the English syndicate, died recently at his home here. Mr. Ralston came from the Pennsylvania coal district 30 years ago, and since then he and his sons have been important factors in the development of the industry in this part of Kentucky.

William Thomas Lewis, first Baron Merthyr of Seughenydd County, Glamorgan, died in London, Aug. 26, at the age of 77 years. He was one of the largest coal mine owners and operators in Wales. He served many years on royal commissions on matters connected with coal mining, trade disputes and various labor questions. He was president of the University College of South Wales and Monmouthshire, formerly president of the South Wales Institute of Engineers, the Mining Association of Great Britain and the Institute of Mining Engineers; vice-president of the Iron and Steel Institute and the Institute of Mechanical Engineers, and chairman of the Monmouth and South Wales Board of Examinations for mining certificates.

CONSTRUCTION NEWS

Philadelphia, Penn.—The Lehigh Valley Coal Co. is making extensive repairs to its big breaker at Beaver Meadow.

Yolande, Ala.—The Yolande Coal & Coke Co. will spend about $30,000 on improvements at Yolande and Abernant mines.

Kittanning, Penn.—The Allegheny River Mining Co. is opening a new mine on the Allegheny River, at Kittanning. This will be known as the Nicholson Run mine.

Euclid, Penn.—The Euclid Coal Co. is opening a coal mine on a 100-acre tract at Euclid station, near New Castle, Penn.. A coal tipple, sidings and a large number of houses for the miners' families will be erected before the winter sets in.

Cincinnati, Ohio—Contracts for the construction of two bridges across the Tug River and two miles of railroad up

Blackberry Creek have been awarded to Boxley, Haley & Co., of Roanoke, Va., by the Norfolk & Western Railway Co., at a cost of $125,000. The construction of this road will add greatly to the coal traffic of the Norfolk & Western, and opens one of the greatest coal territories in eastern Kentucky.

Johnstown, Penn.—The Savan Coal Co., owner of what is known as the Lawry coal tract, near Deckers Point, Indiana County, is pushing work on the railroad from the B. R. & P. Ry. at Savan to the opening, a distance of about two miles, and hopes to be ready to ship coal in the near future. Work on this road was commenced last summer, but was not completed.

Nashville, Tenn.—The Nashville, Chattanooga & St. Louis Ry. has just authorized the erection of a modern steel coaling plant at Hollow Rock Junction, on the Paducah & Memphis Division, and is prepared to expend between $15,000 and $20,000 in this work. The purpose of this coaling station is to take care of the locomotives in this territory as far as Paducah, Ky., also portions of the Nashville Division.

Windber, Penn.—M. E. McNeal is pushing his mining project near Cairnbrook. The tipple and scales are up, the mine is turning out coal, and the railroad line from the mine over the turn of the mountain into Bedford County is being pushed. It will probably be two months before this line is completed over the crest of the hill.

NEW INCORPORATIONS

St. Louis, Mo.—Davis Creek Coal Co., of St. Louis, has been incorporated with a capital of $75,000 by L. L. Brande, J. L. Rowland and J. J. Wells.

Woodsfield, Ohio—The Cambria-Stafford Coal Co. has been incorporated at Woodsfield, Ohio, with a capital stock of $10,000. It will deal in coal lands.

Harrisburg, Ill.—The Oliphant-Wasson Coal Co. has been incorporated here with a capital of $250,000, by C. M. Wasson, G. T. Gaskins and J. T. Gaskins.

Kansas City, Mo.—The Bruce-Cherokee Coal Co. has been organized, with a capital of $2000. The incorporators are J. B. Bruce, M. W. Coulson and V. W. Bruce.

Richmond, Va.—The Himyar Coal Corporation, of Richmond, Va., is increasing its capital stock from $50,000 to $75,000, and changing the common stock from $25,000 to $50,000.

Pittsburgh, Penn.—Announcement has been made of the increase in the capital stock of the Pittsburgh Coal Washer Co. from $12,000 to $50,000. O. J. Tope is treasurer of the company, with offices in the Fulton Building, Pittsburgh, Penn.

Roanoke, Va.—The Carrs Fork Coal Land Co. has been incorporated, with a maximum capital stock of $100,000 and a minimum of $10,000. J. B. Fishburn is vice-president; B. B. Hull, Jr., treasurer, and Leon Neal is secretary, all of Roanoke.

Jackson, Ohio—The Ohio & Indiana Collieries Co has been organized, with a capital stock of $150,000, to deal in real estate, coal, iron and other minerals. The incorporators are E. E. Morgan, Walter McCloud, David Armstrong, M. J. Jones and E. E. Eubanks.

Fairmont, W. Va.—The Liberty Coal Co. has been incorporated with an authorized capital of $2,000,000. The incorporators are Josiah V. Thompson, Robert Howell and H. A. Hibbs, of Uniontown, Penn.; Herman M. Kephart, of Connellsville, Penn., and William H. Burns, of Fayette City, Penn.

St. Louis, Mo.—The Davis Creek Coal Co. has been organized with a capital stock, fully paid, of $75,000. The purpose of the company will be to operate coal mines, buy and sell coal, also to generate and sell electric light and power. The incorporators are J. J. Wells, J. L. Rowland, L. L. Brande, Edwin H. Conrades and R. E. Rombauer.

INDUSTRIAL NEWS

Philadelphia, Penn.—The bituminous tonnage of the Reading Ry. for June, 1914, was 1,230,022 tons ,as compared with 1,293,971 tons for June of 1913.

Connellsville, Penn.—Through a petition recently filed, the Peabody Coal & Coke Co. asked the court to grant it a decree of dissolution. The petition merely set forth that the company has at present neither assets nor liabilities, and that it has been deemed expedient to take this procedure.

Fayette, W. Va.—The heavy coal loadings thus far in the West Virginia and Kentucky fields have led officials of the Chesapeake & Ohio R.R. to feel assured that the coal-loading record of the road will be broken.

New York City—G. A. Kreutzburg, president of the Wolf Safety Lamp Co., is making arrangements to have the Wolf lamps manufactured in this country, in case European hostilities cut off the supply from Germany for any considerable period of time.

Duluth, Minn.—While Duluth coal men are not hesitating to urge customers to buy fuel early, they place no faith in the report of a probable coal shortage. There are more than 8,000,000 tons of coal stored at the Duluth-Superior docks, according to accurate estimates.

Olympia, Wash.—The Public Service Commission recently announced its decision to order into effect the reduced rates on coal shipments from Roslyn to all points named in the recent tentative order. The final order in the case will probably become effective in a few days.

Manchester, Ky.—One of the biggest timber and coal land deals that have been made in this region for some time is being consummated in Clay County. Scranton, Penn., parties have purchased some 40,000 acres of the finest coal and forest land to be found in the Kentucky mountains.

Mobile, Ark.—A voluntary petition in bankruptcy was recently filed in the United States District Court by the Markley Coal Co., a corporation of Mobile, declaring its assets to be nothing and its liabilities $46,777. This company was connected with the well known Markley-Miller operations.

Ketchikan, Alaska—Coal en route to this port on board the Canadian Pacific freight steamer 'Princess Ena," and consigned to the Northland Dock Co., of Ketchikan, was seized by the British Government at Prince Rupert recently, and loaded there on board the Canadian cruiser "Rainbow."

Chicago, Ill.—A substantial increase in the coal tonnage of the Central Freight Association territory accounts for the decerase of 24,738 cars in the surplus freight cars on railroads reporting to this association. On Aug. 15, there were 174,260 cars, of which 75,272 were box, 7189 flat, 56,560 coal and gondola and 35,259 of other kinds.

Halifax, N. S.—The Nova Scotia Government recently sent a message to His Royal Highness, the Duke of Connaught, that Nova Scotia would be glad to deliver 100,000 tons of coal for such purpose as would best serve the interest of the Empire at the present time. Landed at Halifax, this coal tonnage would be worth approximately a half million dollars.

Thurmond, W. Va.—The west end of the Chesapeake & Ohio R.R. bridge over the New River, at this place, was badly damaged a few days ago, when a yard engine derailed two 70-ton steel coal cars on the bridge The structure was temporarily repaired so that empties can be handled over it, but until other repairs are made, loaded cars will be handled by way of Sewell, over the Southside branch.

Pittsburgh, Penn.—Pittsburg coal operators are preparing to resume more activity in mining in the immediate future than at any time this year. During the summer, not more than 35 per cent. of the mining capacity has been employed, owing to the congestion of coal on Northwestern storage docks. Recently, reports have come that the railroads are commencing to move the stock coal in the Northwest in empty grain cars brought to the Lake ports from the West.

Birmingham, Ala.—Alabama coal operators are greatly interested in the announcement from South America that unless the railroads there receive a supply of coal before long, they will have to cease operations. Chile has an inquiry in for 300,000 tons of Alabama coal. As soon as banking arrangements have been perfected, the business will be handled by operators in this district. Ships to handle the coal are already promised through the port at Pensacola. This order will be followed by others, and shipments when once started are to be steady and of large tonnage.

Johnstown, Penn.—The Graff interests recently purchased several thousand acres of coal and coal land in Loyalhanna and Salem Townships, Westmoreland County. These tracts lie about a mile south of Salisburg and five miles north of Andrico. It is confidently believed that the Crabtree Branch of the Pennsylvania R.R. will be extended from Andrico to Saltsburg, where it will connect with the West Penn. The building of this railroad will not only open up a big section of coal land for development, but would give residents of the Kiski Valley direct railroad communication with Greensburg.

Coal Trade Reviews

General Review

Anthracite slows down to a more conservative basis. Much of the West Virginia high-grade bituminous fuels now out of the market. Large contract closed with the Italian Government. Internal business adversely affected by slow industrial conditions.

The heavy anthracite demand of the past few weeks has slowed up to a certain extent, although the market is still active. The Western trade, which anticipated a shortage when the European war developed to such large proportions, started an active buying movement that culminated last week in a situation resembling mid-winter activity. Although still strong, there is a possibility of a relapse before the actual fall business opens up in full blast. All the prepared grades are in good demand at the full circular, with the possible exception of egg.

A large contract business is noted in the Atlantic coastwise trade, particularly as regards the Pocahontas and New River fuels; a big volume of these is either under option or already disposed of, and there are persistent rumors of an impending shortage. As regards the Pennsylvania coals, in the export trade, there seems to be little possibility of these becoming a feature in that business until the West Virginias advance to at least $3.25, or 50c. above the prevailing level. One of the most important developments of the week was the closing of a contract for 350,000 tons for the Italian Government.

The ordinary consumption seems to be reduced to a minimum, and there is scarcely any spot demand at all. On the other hand, shipments to tidewater are heavily restricted and reports indicate that supplies are even lower than usual, while there is a firmness to quotations that is strongly indicative of higher prices later.

In Canada, there are many reports of large transactions at profitable figures, when, as a matter of fact, the regular circular is being maintained with great difficulty; buying is erratic and fluctuating to both extremes. The Ohio market is suffering from the general business depression, steam consumption being light and little money in circulation. The domestic situation is improving, however, and prices are steady at the full circular.

The Southern market reports export inquiries from South America aggregating half a million tons; the business is competitive with West Virginia operators, and the local companies are making a strong effort to secure it. At present, it seems to hinge largely on the question of charters.

Contradictory conditions prevail in the Middle Western trade, substantial advances on the one hand being offset by like recessions on the other. As a rule, the demand seems to be improving as the fall season approaches, and the situation is expected to be materially improved by the close of the current month. The steam market continues the weak department, the restriction in industrial operations having curtailed the demand for these grades.

ATLANTIC SEABOARD

BOSTON

Large volume of Pocahontas and New River sold for export; a shortage expected for coastwise shipment. Pennsylvania grades in strong position and a comprehensive business expected. Georges Creek also in demand off-shore. Anthracite trade good and plenty of orders on hand for September.

Bituminous—Things in Pocahontas and New River have developed sufficiently the past week to cause some uneasiness among New England buyers. Most of the agencies have little coal available at Hampton Roads for September and October, so a large volume is either under option or actually sold for loading off-shore. There is a considerable demand from Mediterranean points and from other directions there is already inquiry for coal that will be mined 60 and 90 days hence.

Coastwise, the movement is still confined to contract business, and while prices have not advanced either f.o.b. or on cars there is a notable firmness that seems to forecast higher prices later. There are practically no cargoes offering on the market, but on the other hand no spot demand of any account has yet developed here.

The Pennsylvania grades continue in a strong position and conditions improve almost daily. Both all-rail and at tide, coal is in better request even than last week and several of the larger shippers are laying plans to handle a comprehensive business this fall. The mines are on better time and no doubt something will be heard on prices before long. Shippers are watching the export market closely and it is more than likely that there will be something of a tonnage to be loaded at Philadelphia for foreign points.

Georges Creek receivers here are beginning to worry over the outlook for sufficient supplies of that grade. Already foreign steamers are being given preference in loading, coal being held for them while coastwise boats wait, and it will not be surprising if New England again runs short of this popular grade. Unquestionably, the shippers are much interested in the off-shore market, with an eye to business in the future, "after the war."

In Water Freights there has been no special development since last reports. Rates are firm but a further advance has not materialized so far.

Anthracite—An unexpectedly heavy demand came on the last of August and practically all the companies are carrying orders over into September. The retailers are beginning to be swamped with orders and they are, in turn, ordering coal freely of the shippers. Stove is expected to be in even shorter supply in a few weeks.

Quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.90@1.50	$1.25@1.70	$1.67@1.77	
Philadelphia*	2.15@2.75	2.70@2.95	2.92@3.02	
New York*	2.45@3.05	2.80@3.25	3.22@3.32	
Baltimore*	.....	.....	2.85@2.95	
Hampton Roads*	.....	.....	.....	$2.85@2.95
Boston†	.....	.....	.....	3.68@3.83
Providence†	.....	.....	.....	3.60@3.68

* F.o.b. †On cars.

NEW YORK

Uncertainties still predominate the bituminous market, though the outlook is favorable. Italian contract for 350,000 tons closed. Anthracite slows down to a more conservative basis. Operations in the mining regions still heavy.

Bituminous—Aside from the active inquiry in export business, which is culminating in an occasional order, the local bituminous situation continues slow. The abnormal conditions prevailing as a result of the European wars, has caused many uncertainties in the business situation here. Some branches of manufacturing are benefited while others have been compelled to curtail or close down completely with the result that the coal consumption is fluctuating widely.

One of the most important developments of the week in export circles was the closing of a contract by the Davis Collieries Co. for 350,000 tons of coal for the Italian Government, shipment to be made in Italian bottoms. While no details are available this is probably for West Virginia coal. It is not generally believed that the Pennsylvania fuels will be able to break into the export business until Hampton Roads prices touch $3.25 to $3.50 or 50 to 75c. above the ruling level.

The situation at Tidewater is considered quite favorable at the moment. Business is slow and orders rather light, but there is no coal of any description reported on demurrage; on the contrary supplies are reported rather short. The movement on the Pennsylvania R.R. is delayed and considerable coal is reported blocked around Altoona. Mines as a rule are working good and prices are steady though at the relatively low level prevailing for the past few weeks as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.55@2.65; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

Anthracite—There has been a conservative slowing down in the hard coal business though the situation is still active. With the gradual development of the war situation, the early

part of last month, anthracite consumers, particularly in the West, began to anticipate a shortage, with the result that by the middle of the month a heavy buying movement developed attaining almost mid-winter proportions. It was purely a psychological condition, but it was instrumental in moving a great deal of coal.

All of the prepared grades are still firm with the possible exception of egg coal which is still occasionally offered at cut prices. The heavy demand for stove coal in all directions has helped materially to move the surplus accumulations of egg and nut coal at the full circular. Pea is growing in demand. In the steam fuels there is little of the individual high-grade varieties offered at cut prices; concessions are still heard on the lower grades though the market is not by any means flooded.

The line trade continues the leader, the Western demand for nut coal being unusually heavy, and the Canadian call for stove and nut being accentuated by the European wars. This may be taken as an indication that there will not be any surplus coal at Tidewater this fall.

Practically all the mines are working on full schedule, and a very active situation is anticipated when the winter demand opens up. The local market is now quotable on the following basis with the new September circular in effect:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.10	$4.60@5.10	$5.05	$4.55@5.10
Egg	5.35	5.10@5.35	5.30	4.95@5.30
Stove	5.35	5.35	5.30	5.30
Chestnut	5.60	5.50@5.60	5.55	5.35@5.55
Pea	3.55	3.45@3.55	3.50	3.20@3.50
Buckwheat	2.80	2.75@2.80	2.50@2.75	2.10@2.75
Rice	2.30	2.30	2.00@2.25	1.60@2.25
Barley	1.80	1.75@1.80	1.75	1.30@1.75

PHILADELPHIA

Better tone to anthracite market. Local conditions improving, and increased operations at mines. Little change in the bituminous situation, but trade looks for gradual improvement.

Anthracite—There is no doubt but what the situation shows a marked improvement. Line and local operators state that they are receiving many inquiries, and the retail dealers report that coal of all sizes is commencing to move. The return of house holders and the almost universal idea that coal is likely to be short the coming winter, is having its effect, and more coal wagons are seen on the streets than has been the case for a couple of months. Most of the dealers are well stocked, however, many of them carrying over considerable coal from the spring months, and it will possibly be a couple of weeks before they begin taking on additional supplies in appreciable quantities. In the meantime, the individual operators still stand ready to fill any gaps at less than circular.

It seems the concensus of opinion in the trade, that the demand will not only come early, but continue particularly strong throughout the winter months, and the dealers are laying their plans accordingly. Outside of chestnut and pea coal, which need the stimulus of a low price to move, the trade is absorbing practically all sizes. Operations at the mines were continued last week at five days, and it is understood that this program is likely to be followed until the market can absorb the full weekly output.

Prices at Tidewater rule about as follows:

	Circular	Individual
Broken	$4.75	$4.75
Egg	5.00	5.00
Stove	5.00	5.00
Chestnut	5.25	4.90 @ 5.00

Bituminous—There seems to be better feeling in the bituminous trade. While mining still continues under a curtailed basis, many operators seem to have optimistic opinions regarding the near future. This is indicated by the almost general attitude of the trade on future business; spot coal is anywhere from 25 to 30c. less than a quotation for future delivery, which certainly spells better conditions to come.

BALTIMORE

Interest centered on export possibilities. Local conditions remain flat, but big change is looked for in the near future. Surplus at tide disappearing.

With home conditions slow it is natural that the eyes of the coal trade should be turned toward the new possibilities in the export business. From every quarter of the globe come inquiries for fuels to take the place of Welsh coals that have been withdrawn as a result of the European war. A number of contracts have been closed on these advances already, and a great field is opening up. This call is for the better grade coals.

Industrial conditions are so poor for the present that there is little doing here for domestic consumption. Cheap fuel is offering freely at the mines. West Virginia gas three-quarter was selling to the trade as low as $5 in places; steam coals are around 95c. In the Pennsylvania regions the medium to poor grades are selling at from $1 to 1.10. First grade coals are showing a little inclination to stiffen, and are selling from $1.25 to $1.35.

Under the growing export movement of both coal and grain, which requires cargo and bunker coal, the big surplus at tide is fast disappearing. Some unexpected coal loadings for Norway and Greece the past week took care of part of the free coal at tide. Charter rates to foreign ports are abnormally high but more bottoms are offering now that Britain and France are in control of the sea. Coastwise bottoms are offering easily and there is little or no change of rate to be noted.

Anthracite men report a little better inquiry. No general awakening is predicted for less than three weeks or a month, however.

HAMPTON ROADS

Export shipments continue heavy. Rumors of sales negotiated at prices above circular. Government transports taking considerable bunker fuel at Newport News.

Shipments from tidewater during the week have been heavy. This is especially true as regards export movement, although coastwise shipments have also shown up well. The demand for all grades shipped from Hampton Roads still continues good, although it is reported that some large lots have been sold at prices above circular it is difficult to get this confirmed.

The market is full of inquiries from various foreign countries. It is understood that about 100,000 tons has been sold to parties in Greece and that this coal will begin to move during the next few days. Export shipments have been made to Havana, Cardenas, St. Lucia, Callao, Para, Bahia Blanca, Rio, Buenos Aires, Manaos, Kingston, Genoa, Naples and Lisbon. There has also been a small movement via schooner to San Juan, Porto Rico.

The United States Government has taken considerable coal at Newport News for transports which are due shortly to sail for European ports.

Both Sewalls Point and Newport News at this writing are within a few thousand tons of the August, 1913, dumpings and unless tonnage due fails to arrive during the next two days the total of these two roads for August, 1914, will be in excess of last year. Lamberts Point figures are not obtainable at this moment.

COAL CHARTERS

Coal charters have been reported by the "Journal of Commerce" as follows:

Vessel	Nationality	From	To	Tons	Rate
Standish Hall[2]	British	Virginia	Rio Janeiro	2544	
Haxby[2]	British	Baltimore	Genoa	2252	
Warren Adams[1]		Philadelphia	Charleston	587	
Kate B. Ogden[1]		Philadelphia	Charlottetown, P.E.I.	541	$1.60
Georgina Roop[1]	British	Philadelphia	St. John, N.B.	423	1.50
Ramazan[2]	British	Norfolk	Rio Janeiro	2211	5.40
Edison Light[2]	American	Philadelphia	Rio Janeiro	1699	
Bratlingsborg[2]	Danish	Virginia	River Plate	1963	4.80
Edith[1]		Baltimore	San Juan, Porto Rico	1051	

[1] Schooner [2] Steamer

LAKE MARKETS

BUFFALO

Conditions mixed in both anthracite and bituminous. Situation not greatly affected by war except in Canada. Home consumption less than normal. Better demand anticipated.

Bituminous—As a rule it is held that the war is going to help this country, but a period of depression is expected before the benefit is felt and it is a question how long that will last. There is a report from Pittsburgh that the war has not improved the export trade at all and there is no prospect of orders on that score. Home business has been injured by it so that the coal business so far has only sustained a loss. Canada has lately bought considerably more coal than it has used but this is no real advantage, as the time will come when that coal must be used and buying will cease. There is evidence that Canadians are much more puzzled over the outlook than is the case with us. Buying is erratic, fluctuating to both extremes. On this account the jobber and shippers hardly know what to do. A Buffalo salesman is just back from a visit to Montreal with the report that there is an over-supply on hand now.

There are many false reports of transactions. Some members of the trade appear to think that every unusual order placed is for use in the war somewhere. There is no change in the semi-official circular. Much of the poorer coal

sells for less but prices continue nominally as follows: $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.15 for slack, the different sizes being fairly on a level as to strength. Allegheny Valley slack is about on a par with Pittsburgh, but sizes are 15 to 25c. lower.

Anthracite—The demand is improving, though neither shippers nor local dealers are sure that the stir is the beginning of the fall rush. Practically all sizes are asked for. Canada has bought so much of late that it will probably drop out when other sections start buying. The big apple crop has created a demand for grate, which is used in the apple evaporators. The independent dealers get a large part of this trade.

There is a good amount of anthracite moving out by Lake, but the rush of June and July cannot be kept up. There is getting to be a very large amount on the Upper-Lake docks and till it begins to sell there will be light shipments. The amount loaded during the week, as recorded by the custom house was 78,000 tons.

TORONTO

Usual fall increases begin earlier than customary. Still considerable stocking.

The usual fall increase in the price of anthracite occurred this season a little earlier than usual. There is a heavy demand for domestic purposes and dealers are very busy making deliveries, many consumers laying in stocks in anticipation of a possible embargo on coal by the United States. The call for steam coal is steady and prices somewhat higher, quotations being as follows: Retail—anthracite, egg, stove and nut $7.75, grate, $7.50, pea $6.50; bituminous, steam, $5.25; screenings $4.35, domestic lump, $6, cannel, $7.50, wholesale f.o.b. cars three-quarter lump, $3.83, screenings $2.89.

TOLEDO

Lake shipping much stronger and considerable coal going to Canada. Some predict stronger prices shortly. The domestic market a little better.

The domestic market is showing considerable strength in these quarters. The steam trade continues light due to the fact that Toledo factories are for the most part only running at about two-thirds capacity. Money is tight and this has a depressing effect on business generally.

Lake shipping is more active than it has been for months and a great deal of coal is going into Canada although dealers do not have much to say about this feature of the business. Some of the railroads are ordering new equipment but it is generally conceded that should there be a very heavy grain movement there will be a severe car shortage. However, farmers are strongly inclined to hold their products in the hope of securing war prices and this may save the day so far as the traffic situation is concerned. There is no change in quotations as yet although higher prices are predicted for domestic grades.

CINCINNATI

Domestic grades slowly improving, strengthened by the foreign demand and the customary increase in local orders. Steam business remains slow, industiral concerns operating on short time.

The situation is more nearly normal, save for the general slackness which has marked the whole year. Returning domestic consumers are making arrangements for their winter fuel, bringing the retail trade better business than it has had for some time, although nothing like the usual volume is yet in evidence; this is being reflected to a certain extent in the demand at the mines. Many dealers are so fully stocked that they appear determined to wait still longer before ordering new supplies in any quantities, but in spite of this fact, the domestic market is in better shape than for some time. Prices are steady at circular, with the possibility of premiums by no means remote.

In the steam market there has been more of a decrease than an increase in the demand. The sluggishness is due to dullness in the numerous industries whose operations normally call for a large consumption of fuel, somewhat emphasized by cancellation of orders from Europe. The expected stimulation, due to increased demand from other markets, has not materialized as yet and many lines of business are running on much slower time than before. The general feeling, however, is optimistic.

On the whole the situation is much improved. Transportation facilities are excellent, and the Lake movement continues steady, although relatively light in volume. There is very reason to believe that production and consumption will be about normal from now on, with prices at a profitable level.

DETROIT

Domestic grades fairly strong and some stocking is noted. Favorable outlook in anthracite.

Bituminous—The steam trade is slow, as is naturally to be expected with industrial conditions generally at such a low ebb. There is a noticeable leaning toward the open market among consumers, and contracts are still slow in being closed up. The domestic grades are the strongest at the moment. The stocking-up season is opening up briskly, particularly on the West Virginia grades, with Hocking Valley also in good demand. The West Virginia splint lump-coal is quoted at $1.60, three-quarter lump at $1.25, Pocahontas lump at $2.50, with mine-run at $1.50, and Hocking lump at $1.60. A general increase on nearly all the grades is scheduled for the near future.

Anthracite—Should the European war result in diverting much of the smokeless coal into the export market, the local anthracite situation will be much benefited. The West Virginia smokeless fuels have made heavy inroads in the local hard-coal market in recent years, and in the event of a shortage of these, the anthracite jobbers will regain much of their lost ground.

COKE

BUFFALO

Coke shippers are unable to see any improvement in the demand. The movement of iron ore is fairly brisk, some local furnaces not having much of a supply, though the receipts are good. This apparent contradiction may mean that someone is storing up ore for future activity, but at the same time they do not try to take advantage of the coke market. Quotations remain on the basis of $4.25 for best 72-hr. Connellsville foundry, with stock coke $3.25.

DETROIT

The demand is increasing, while shipments are coming in rather slowly, with the result that the high-grade cokes are commanding a slight premium. Connellsville 72-hr. foundry is quoted at $3.75, and Solvay at $4, with gas house at $3.50, all f.o.b. ovens. Connellsville retails at $6.50 per ton and Solvay at $6, although it will probably advance to $6.50 by the middle of the current month.

ST. LOUIS

A small amount of byproduct domestic coke is moving in, and in the past week a fairly good tonnage of foundry coke passed through St. Louis. The local demand is light. Local gas house coke for domestic use is in good demand.

SOUTHERN

LOUISVILLE

Increased demand for domestic coals and mines are working stronger. New September circular in effect.

The quickened demand for domestic coal continues the significant thing in the Kentucky market at the moment; steam coals are in no worse condition than they have been for a considerable time. Generally the mines are rather active, working nearly to capacity. September prices, an increase of from 5 to 10c. all along the line, are now in effect.

The market has hardly become adjusted yet to the new conditions occasioned by the war in Europe though that influence is expected ultimately to prove beneficial.

BIRMINGHAM

European war promises renewed activity in South American trade. Lump coal in slightly better condition and blacksmith grade satisfactory.

The local demand for steam coal is just about the same though slightly heavier for immediate shipment. However, the European war is causing a shortage of coal in South America and Alabama operators have been asked to make prices on several large tonnages, one of 200,000 tons for the Argentine Republic and another of 300,000 tons for the Chilean navy. While it is not an assured fact that this district will get these orders it seems reasonable to believe it will. The United States is now the only country which can supply it, and the operators in this district are making a very strong effort to land it. The main obstacle so far seems to be in obtaining charters to convey the coal. The matter is now being vigorously pushed and results are expected shortly. Birmingham capitalists are also talking of organizing a steamship line for this business, but the matter is being held up until definite information is obtained as to whether necessary ships can be chartered. In addition to these two inquiries, Uruguay and Sweden have also asked for prices.

MIDDLE WESTERN

INDIANAPOLIS

Demand for domestic grades improves slightly and will increase as the month advances, operators predict. Prices are also expected to improve, with the fall demand and the running schedule to increase. Industrial demand slackening, due to war. Retail trade handicapped by closeness of money.

The demand for domestic coal keeps improving a little and will grow as September advances; it takes cool weather to put the householder in buying mood. Mines already have a fair number of contracts for September delivery and operations will likely be increased. That there was a little spurt in August is indicated by the fact that the last semi-monthly pay in the Clinton field was the largest of the summer season.

Trade has since fallen off, however, and in some districts is said to be the lightest for five months. The demand for steam coal is apparently below normal, affected by the slackening up of industrial operations on account of the war. Even factories that have no export trade are affected. Prices remain unchanged but operators seem to be of opinion that they will be higher shortly. Retailers say the financial stringency and industrial situation has prevented considerable stocking of winter coal. With money tight, consumers hang on to every dollar until they have to part with it. Mines are operating on about half-time.

ST. LOUIS

An increasing demand for the larger sizes of domestic coal from the high grade fields. Steam market demoralized.

Franklin and Williamson County lump and egg coal have advanced as much as 25 to 40c. a ton. This is caused largely by the fact that there has been little early buying, and business that has usually been placed in June and July is now coming in. To off-set this, several of the large manufacturing plants are running on half time. and some of them have shut down entirely, so that the future is not the brightest. Car shortage is causing the railroads to refuse to give the mines any cars for the larger sizes as long as they have unbilled steam sizes on track. In the Franklin County field during the past week as many as 90 cars of steam coal have been unbilled by one company.

In the Standard market, while the demand for domestic sizes still continues, yet there is an apparent fear on the part of the operators that if they ask more money the demand will cease: 2-in. screenings are selling at from 30 to 40c., but the price of 2-in. lump is still hovering around 90c. to $1, the last being considered a good price.

There has been an unusual demand and exceptionally good movement of Pennsylvania anthracite in the past ten days. Smokeless is absolutely a drug on the market, with no demand. Arkansas anthracite is picking up some.

	Williamson and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	.....	....	$1.25	$0.90@1.00	$1.10
3-in. lump	.....	....	1.30	.....	.....
6-in. lump	$1.50@1.75	....	1.40	1.10@1.20	1.25
Lump and egg	1.85@2.15	$2.25	.....	....	1.15
No. 1 nut	1.25@1.50	....	.....	.....	.....
Screenings	0.70@0.75	....	0.80@0.85	0.30@0.35	0.35
Mine-run	1.00@1.15	....	.....	0.75@0.80	.....
No. 1 washed nut	1.50@1.60	2.25	1.50	....	.....
No. 2 washed nut	1.25@1.35	....	1.35	....	.....
No. 3 washed nut	1.15@1.20	....	.....	....	.....
No. 4 washed nut	1.00@1.10	....	.....	....	.....
No. 5 washed nut	0.55@0.65	....	.....	....	.....

September prices on Pennsylvania anthracite are: Chestnut, $7.50; egg and stove, $7.30; grate, $7.05. Arkansas grate, egg and chestnut is $6.10 and lump $5.85.

KANSAS CITY

Trade continues to improve, though householders are slow in placing orders. Light wholesale trade is offset by bright prospects later.

A cool spell last week helped somewhat to stimulate interest in coal orders, suggesting the nearness of winter. The approach of September and possible higher retail prices did not create the usual rush orders on the last days. Wholesale dealers and mining companies complain that business is not up to the standard for the season, but they are all hoping for a large increase soon.

Kansas City sentiment in reference to the effects of the war is growing more sanguine, and there is a tendency to reach out for the big trade that America may get from the diminution of activity abroad. Most of the mines in the Kansas district are in operation, and an optimistic tone prevails as to the immediate future. Local stocks are said to be small.

PRODUCTION AND TRANSPORTATION STATISTICS

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic from the New River, Kanawha and Kentucky districts for June and the twelve months ending June 30, 1913 and 14, in short tons:

	June				Twelve Months			
Destination	1914	%	1913	%	1914	%	1913	%
Tidewater	322,008	18	253,448	16	3,560,350	19	3,531,202	22
East	172,686	10	192,316	12	2,561,809	14	2,549,552	16
West	1,192,911	65	1,067,682	66	11,554,335	61	9,221,463	57
Total	1,687,605		1,513,446		17,676,494		15,302,217	
From Connections								
Bituminous	135,357	7	91,617	6	1,169,979	6	729,741	5
Anthracite	1,669		1,794		16,263		15,746	
Total	1,824,631	100	1,606,857	100	18,862,736	100	16,047,704	100
Coke	29,392		30,015		388,752		315,474	

NORFOLK & WESTERN RY.

The following is a statement of coal handled by the N. & W. Ry. during July and the past four months of the current year in short tons:

	April	May	June	July
Pocahontas Field	1,156,670	1,239,653	1,245,440	1,314,478
Tug River District	221,344	263,155	244,342	263,240
Thacker District	232,181	280,148	261,248	288,643
Kenova District	96,116	101,768	97,352	100,600
Clinch Valley District	156,502	150,916	156,028	140,751
OTher N. & W., Territory	2,827	2,596	2,337	2,735
Total N. & W. Fields	1,865,640	2,038,236	2,006,747	2,110,447
Williamson & Pond Creek R.R.	79,828	74,875	76,822	90,819
All other railroads	171,818	225,561	232,387	301,796
Grand total	2,117,286	2,338,672	2,315,956	2,503,062

Destination of shipments over this road for July and the first seven months of this year and last year were as follows in short tons:

	July		Seven Months	
Coal	1913	1914	1913	1914
Tidewater, foreign	155,762	140,848	1,032,082	1,062,893
Tidewater, coastwise	321,340	279,708	2,224,658	2,241,934
Domestic	1,805,368	1,082,506	10,457,182	11,714,556
Coke				
Tidewater, foreign	4,358	182	27,199	197
Domestic	122,716	88,325	940,517	668,978
Total	2,409,544	2,591,569	14,681,638	15,688,558

Distribution of shipments for June and July compare as follows:

	June			July		
	Shipped	Tipple	Total	Shipped	Tipple	Total
Pocahontas	1,136,568	14,804	1,151,372	1,212,483	16,138	1,228,621
Tug River	242,208	2,134	244,342	260,141	3,099	263,240
Thacker	214,595	9,968	224,563	235,410	7,633	243,043
Kenova	88,455	8,897	97,352	89,953	10,647	100,600
Total	1,681,826	35,803	1,717,629	1,797,987	37,517	1,835,504

Shipments of coke, entirely from the Pocahontas field, amounted to 59,370 tons in June, as compared with 62,097 tons

BALTIMORE & OHIO

The following is a statement of coal and coke tonnage moved over this system and affiliated lines during May, June and July of this year and last year:

	May		June		July	
	1914	1913	1914	1913	1914	1913
Coal	2,995,812	2,357,119	2,380,795	3,061,929	2,594,407	2,938,723
Coke	301,163	434,898	298,237	396,920	255,650	391,485
Total	3,296,975	2,792,975	2,769,032	3,458,849	2,850,057	3,330,208

I. C. C. Nos. 5558 and 5558 Sub. No. 1—Hughes' Creek Coal Co. and Kelly's Creek Colliery Co. vs. Kanawha & Michigan Ry. C.

In the sub-numbered case, Kelly's Creek Colliery Co. vs. Kanawha & Michigan Ry. Co., the Commission originally held that the defendants should establish through routes and joint rates between stations on the Kanawha & Michigan Railway and its branches and the points specified in the complaint in eastern and southeastern territory on the lines of the Chesapeake & Ohio and its connections, and that as reasonable rates for these routes defendants should apply rates not in excess of those applying to these destinations for shipments from the mines on the Chesapeake & Ohio. Upon reconsideration of the case; **Held**, That there may properly be a slight difference between the rates applicable to the through routes ordered and those applicable to the single movement on the Chesapeake & Ohio.This difference should not exceed 5c. per ton.

Suspension Docket No. 321—Coal rates from Virginia mines.

1. The rates on coal from the mines in the St. Charles, Va., group to points north of the Ohio River within 400 miles from St. Charles should not exceed the rates from the Middlesboro-Jellico group to said destinations by more than 10c. per ton; beyond that the differential should decrease not less than 1c. for each additional 100 miles.

2. The rates on coal from the mines in the Appalachia group and the mines at Benham, Ky., should not exceed the rates from the Middlesboro-Jellico group to points north of the Ohio River by greater amounts than the present differentials, provided that the differentials of Appalachia over Middlesboro-Jellico, should in no case be less than the differentials of St. Charles over Middlesboro-Jellico.

3. The prescribed differentials being maxima, the carriers are at liberty to establish smaller ones whenever commercial conditions may so require.

4. Respondents required to cancel rates exceeding those prescribed in the report, but suspension order vacated as to all other rates named in the tariff under suspension.

FOREIGN MARKETS

ITALY

The Italian imports of coal and coke for the past three years were, in English tons: In 1911, 692,577 tons; in 1912, 770,592 tons; in 1913, 825,293 tons.

Imports of coal by countries for the past three years were as follows:

Country	1911.	1912.	1913.
Austria-Hungary	85,363	177,307	133,838
Belgium	23,160	24,363	4,358
France	100,110	170,565	164,674
Germany	442,935	889,501	949,113
United Kingdom	8,767,352	8,637,219	9,386,159
Netherlands	157,676	75,494	72,564
United States	14,068	68,032	93,529
Other Countries	5,218	14,747	6,625
Total	9,595,882	10,057,228	10,810,860

ENGLAND

Movement very irregular due to the heavy burden on the railroads. Prices fluctuating though a runaway market has been avoided. Considerable stocking for emergencies.

The London coal trade has suffered a good deal from the effect of the war. Business generally has been seriously interfered with, and consignments have been very irregular. The railways have undoubtedly risen in a marvellous way in their endeavors to cope with the enormous military traffic, but it has meant in many cases a sad delay in getting coal traffic forward. The southern lines have had great quantities of empty coal trucks waiting at various points, and in the meantime, very few collieries have had their full complement of empties to work with, besides which loaded wagons have waited sometimes a day or more before they can be removed from the colliery sidings.

Prices continue very irregular, but as a general rule the trend of market quotations is lower this week than last. Many of the Yorkshire collieries are offering both house coal and hard steam coal freely on the London market, and as a rule the natural outlet for these qualities is coastwise, or for export. The tendency last week was undoubtedly towards an advance in pit prices, but the extra quantity offering during the current week has distinctly checked all movements in that direction, and more than balanced the demand and the supply.

The depots still report an enormous quantity of unexecuted orders from the general public, the result of the first rush for coal when the war first broke out, but in many cases merchants are now delivering only the coal that is actually paid for, and making that a condition for entering the larger orders received at the time of the scare. The main object of the offer recently made by Messrs. Rickett, Smith and Messrs. G. J. Cockerell and Co. to place 350,000 tons of coal at the disposal of the Government at $5.76 and $6 per ton for the north and south respectively, of the Thames is to prevent or relieve distress for want of fuel during the coming winter.

One of the most serious aspects of the war as it affects the London trade is the closing of so many of the North London stations to the general public for so many days, whilst the troops and ammunition, together with the horses, baggage, field guns and accoutrements, are being moved from one place to another.

RUSSIA

Imports of coal and coke into Finland for the last two years were reported as follows in metric tons:

From	Coal 1912	Coal 1913	Coke 1912	Coke 1913
United Kingdom	457,385	497,636	10,012	24,342
Russia	278	.....	62	.....
Sweden	918	909	176	.....
Germany	5,190	13,874	13,930	20,150
Netherlands	23,727	22,611	5,055	3,755
Belgium	412	.....	1,565	.....
Total	487,911	536,975	30,801	48,638

FINANCIAL

Delaware & Hudson Co.

This company reports in part for the calendar year of 1913, as follows:

During 1913 this company mined 7,170,553 gross tons of anthracite, out of 69,069,628, including product of washeries, produced in the region, or 731,998 more than in 1912, when production was reduced by suspension of mining from Apr. 1 to May 21. During 1913 there were ten strikes which caused temporary idleness of one or more collieries, loss of time being equivalent to closing of one colliery 491 hr., or 54 5-9 working days.

This company has endeavored to conduct mining operations with adequate regard to protection against caving. Recent discussion, particularly in Scranton, has been accompanied by extreme demands which, if admitted would greatly enhance cost per ton recovered and materially reduce ultimate proportion of total in ground that could be made available.

Causes, some of them legislative, and all beyond control of railway managers, which during recent years have enhanced difficulties attending effort to maintain reasonable margin between revenues and expenses, were not less effective during the year. Increases in wags, consequent on arbitrations which, although nominally requiring voluntary acquiescence of railways, really operate, under ordinary circumstances, with compulsory force, supplemented by reductions in hours of labor and relaxations in conditions necessary to secure from each unit of labor its maximum of reasonable efficiency, and increases in prices of materials and supplies, themselves mainly attributable to higher wages and lower efficiency of labor, have greatly augmented expenses. At the same time the taxing authorities have continued to impose a heavier proportion of steadily rising expenditures of government. Concurrently, the process of attacking rate schedules in detail, reducing here a rate and there a group of rates, has operated to reduce gross.

COAL AGE

Vol. 6 NEW YORK, SEPTEMBER 12, 1914 No. 11

As It Might Be

By Berton Braley

Written expressly for Coal Age

"'Twas a wonderful dream," said Dugan,
"The dream that I dreamed last night,
For I thought I wint to a fancy mine
Where the breaker was painted white
An' the coal on the belt conveyor
Was polished until it shone,
An' wrapped up in tissue paper
An' scented wid sweet cologne.

"An' instead av the breaker huskies,
Was beautiful girls—'tis so—
Wid gloves on their lily fingers
An' uniforms white as snow,
They handled the coal wid tweasers,
An' a boy wid an inlaid tray
He tuck the slate as they picked it out
An' carried it all away.

"They'd gilded the hoisting engine
An' the cables was gilded, too,
An' the cages was finished in blue an' gold
A wonderful sight to view,
An' all of the lady miners
Was natty an' spick an' span,
Wid their handcarved picks an' their jeweled lamps
An' each wid her ivory fan.

"They'd kalsomined all the entries
An' papered most every room,
An' Japanese lanterns was all about
Dispellin' the heavy gloom,
They'd muffled each drill an' cutter
An' carpeted every floor,
An' bouillon was served 'em at half past one
An' tea was at half past four.

"So I says to the lady foreman
(A regular handsome queen),
'Say, who is the boss of this spotless mine
An' what does the whole thing mean?'
An' she says, "Tis an object lesson,
An' its glory shud travel far,
For this mine is run by the Woman's Club
Wid the aid of the D. A. R.!'

"'Twas a wonderful dream," said Dugan,
"I'm sorry 'twas done so quick,
For I hadn't quite—there's the pit boss now,
Say, gimme that bloomin' pick!"

The Ramsay Revolving Car Dump at the Woodward Ore Mines

By H. S. Geismer*

SYNOPSIS—A revolving dump which handles four loaded cars weighing 40,000 lb. gross. The actual dumping requires only about two seconds, while the entire process of weighing the loaded cars, dumping and reweighing the empties requires about one minute.

The announcement that the H. C. Frick Coke Co. has contracted for a revolving car dump (of the type patented by Erskine Ramsay, of Birmingham, Ala.) for its Lemont No. 2 mine, which will be 176 ft. long and will be capable of dumping a trip of 18 mine cars without detaching from the haulage rope, led to the belief that a description of one of these dumps now in operation would be of interest to coal-mine officials.

Fig. 1. A General Side View of the Dumping Plant

The dump shown in the accompanying illustrations was installed by the Woodward Iron Co. at its iron ore mine, Slope No. 3, near Woodward, Ala., about five years ago, and has been in continuous successful operation ever since. It is designed to handle four loaded cars containing a maximum of 30,000 lb. of ore in addition to a tare weight of 10,000 lb., or a total weight of 40,000 lb.

The average time consumed in stopping the trip on the scale, weighing, pulling the cars into the dump, dumping and passing the scale on the return trip is one minute. The actual time required to revolve the dump is only about two seconds.

The loading of the ore at this particular mine is done by contractors and the contents of all of the four cars on any one trip belongs to one man. This simplifies the work of weighing considerably, as the four cars can be weighed and credited by a single entry on the tally sheets and only one check is required to be placed on each trip.

The average length of haul to the various entries off the main slope from the mouth of the mine is ⅜ of a mile, and the average time consumed in making the round trip into the mine, including the time required to do the dumping, is six minutes.

The average output of the mine is 900 long tons, and this is generally handled between the hours of 10 a.m. and 5.30 p.m. Between 7 and 10 a.m., most of the men are timbering and loading, and the hoist is kept busy handling material.

The dump is revolved by means of an air-operated piston in a vertical cylinder, which may be plainly seen in the illustrations. The up-and-down movement of the piston is transmitted to the dump cylinder by means of a wire rope. On the up-stroke of the piston, the dump

*Keiser-Geismer Engineering Co., Birmingham, Ala.

Fig. 2. Another View, Showing Weigh House, Dump, Cable and Operating Cylinder

is revolved about 200°, and then, on the down stroke, it is brought back to normal position.

In some of the dumps now built, the cylinder is designed to receive a complete revolution in one direction on the up stroke, and a similar movement but in the opposite direction on the down stroke. In this way, the coal or ore is dumped into the two sides of the bin underneath, alternately.

The power used in the cylinder of the Woodward dump is compressed air, at about 75 lb. pressure. This is piped from a receiver which furnishes air to the rock drills on the inside of the mine, to a small horizontal receiver shown in Fig. 1, just to the left of the vertical cylinder. The operating power generally used is steam, but at this plant no steam was available near the tipple location.

Only One Man Required for Dumping

One man only is required to operate this dump to its capacity. He weighs the cars first; then, after they have entered the dump, he discharges their contents by ma-

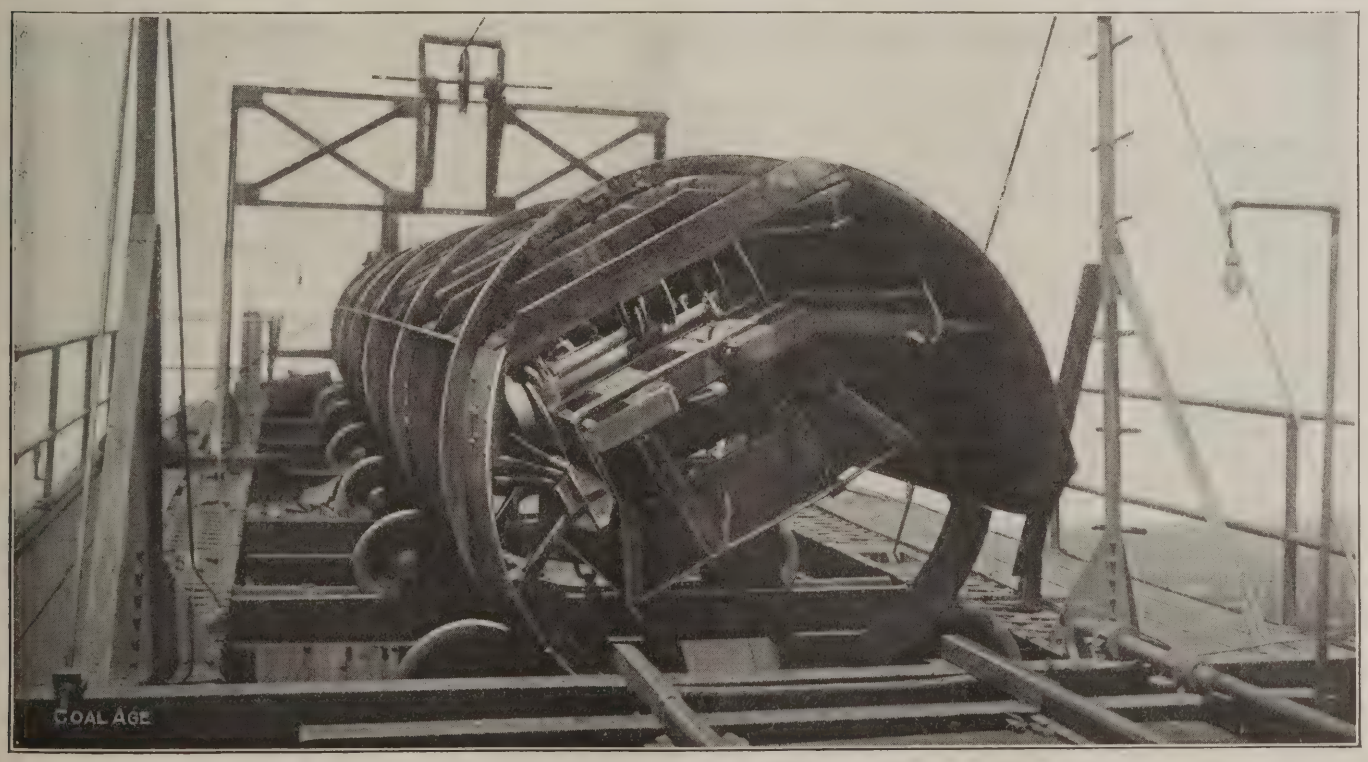

Fig. 3. The Revolving Dump in Operation

nipulating a valve in the weigh house. The dump is built on an inclination of approximately 12 per cent., which is sufficient to start the cars back by gravity, as soon as the hoisting engineer gives slack rope. The hoist is a geared electric machine and is located a few hundred feet from the dump, and exactly over the center line of the slope. As one man operates the hoist, only two men are required to do the hoisting and dumping.

In Fig. 0 the trip of loaded cars is shown standing on the scales; the small building just beyond is the weighman's house, and the scale beams are clearly seen extending horizontally about midway between the ground and tipple floor. The scale is also plainly shown in Fig. 1.

In Fig. 2 the trip of empty cars is seen just ready to start back into the mine. Fig. 3 shows the dumping cylinder revolved 90° and the cars beginning to empty.

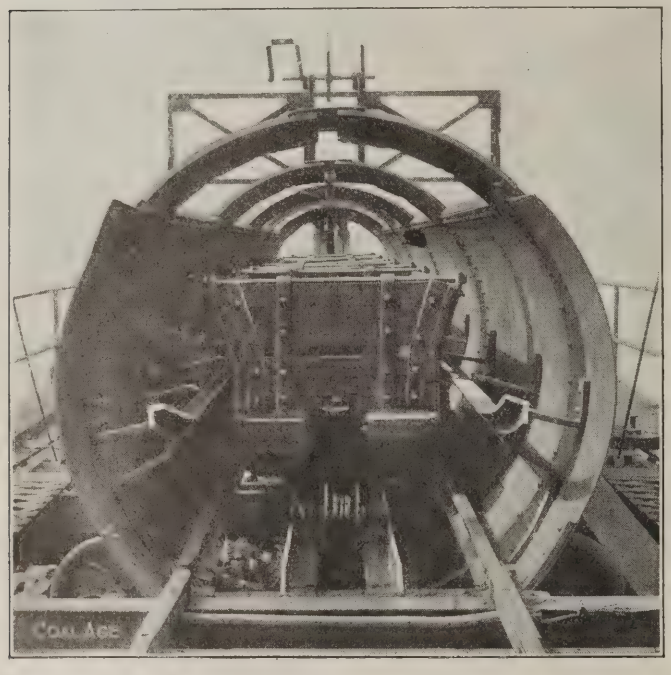

FIG. 4. THE TRIP AFTER DUMPING; READY TO RETURN TO THE MINE

In Fig. 4, the inside of the revolving cylinder can be seen distinctly, also the car wheels on the outside upon which the cylinder is supported and revolves.

By referring to Fig. 1, it will be seen that the ore, after being dumped into bins, is fed by gravity into a gyratory crusher underneath, from whence it drops into railroad cars and is hauled to the company's furnace located only a few miles distant. The entire tipple, with the exception of the siding of the bin, is constructed of steel.

Dumps similar to that employed at Woodward have been installed and are now in operation at coal mines as follows: One in Pennsylvania, two in Tennessee, one in Utah, one in Alabama. Those now in operation were designed for capacities varying from two to six cars.

THE ADVANTAGES OF THIS TYPE OF DUMP AT COAL MINES

In considering this type of dump for coal-mine service, several distinct advantages are apparent. A car without drop bottom or end grates can be used, which eliminates largely the scattering of coal along the haulage ways, due to fine particles sifting through cracks, and also the accidental opening of doors, while the trip is in motion, often at high speed. This reduces, to a marked degree, the liability of dust explosions, and also cuts down the cost of maintenance on haulage ways.

It further eliminates, to a noticeable extent, the number of wrecks on haulage roads and the troublesome delays that follow, especially where mechanical haulage is employed. The solid-end car is also lighter and consequently easier to handle than any other type, and costs less for repairs, as it is much more rigid and will stand more abuse.

Only during the past few years has the importance of keeping haulage ways free from coal dust been fully understood, and, as a result, the demand for tight, well constructed cars is becoming more and more noticeable.

This type of dump is not as hard on cars as the ordinary horn dump, since the cars are not stopped and started suddenly; even while they are being revolved they are held firmly in place, by means of the angles just over the wheels, as illustrated in Figs. 3 and 4.

To reduce the breakage to a minimum, where lump coal is desirable, a bin can be constructed the entire length of the dump, with sides coming up close to the edge of the cars when they are in dumping position.

The Bonding of British Exports

SPECIAL CORRESPONDENCE

The British government is urging the merchants and traders of the United Kingdom to go on with business as usual. They desire especially that the export coal trade should continue to neutral countries, as otherwise thousands of sailors, dock workers, railway employees, and miners will become idle, increasing the number of those for whom relief work must be found. The coal exporters have replied that they are willing to keep their trade going in the face of the serious war risks and the chance of nonpayment, but they cannot undertake the serious handicap imposed by the government in the form of a bond for treble the value of a cargo. The coal exporters feel that the government is putting the responsibility on the wrong party.

If the bond cannot be entirely removed, the coal men feel there ought to be an exemption in the case of British ships with cargos for a neutral port. An affidavit or declaration of destination should be sufficient, with proof of arrival. In the case of neutral ships a bond for a reasonable amount should be required of the owners or masters, with British sureties, and proof of arrival but not of delivery.

The matter is of such vital interest to the coal exporters of the United Kingdom that the shippers of the Bristol Channel, Humber, Tyne and Scotland have made joint representations to the government and have asked them to receive a deputation of representatives of all these districts, so that their case may be placed before the proper authorities.

The electric conducting power of a substance is usually expressed in terms of its resistance, rather than conductivity. A wire that is high in conductivity is low in resistance, and vice versa. Resistance is that property of a conductor, by virtue of its form and molecular structure, which modifies the strength of current flowing through it. It is an inherent property of all electrical conductors. Even the best conductors possess appreciable resistance.

Shaft Sinking in the Central Field of Alberta

By E. I. Roberts*

SYNOPSIS—The machinery and other equipment necessary to sinking operations in this field are enumerated, the organization and method of procedure detailed and an estimate given of the total cost of a shaft per lineal foot.

It is my desire to show some of the difficulties experienced in shaft sinking in the Central Field of Alberta and to explain how they may be overcome.

The methods and expense of sinking operations are controlled by three factors: First, the mine location relative to the base of supplies; second, the condition of the country; third, the class and expense of labor.

In the first place, machinery and supplies are obtained from eastern Canada, Great Britain or the United States, meaning a considerable delay before material reaches the field, therefore with all machinery orders there should be sent a complete order for repair parts.

A good plan for a person considering shaft sinking is to order material and supplies in October, so that operations in the field can be commenced in March or April of the following year, enabling a whole summer's work to be done before winter holds up the work. The spur from the railway to the mine site will also delay operations, and six months has to be allowed therefor.

The second factor is the nature of the country. It may be prairie, or rolling and timbered. On the former, every supply has to be shipped in, and test holes for water bored, while in rolling and timbered localities, sufficient creeks are found, as well as material for temporary structures.

In the estimates, allowance should be made for clearing the mine site and for extra engineering costs, when country is timbered. Camp and boarding supplies may be obtained from neighboring farmers, or if the surrounding homesteads are not settled, all these have to be shipped in.

The last factor is that of labor. This in the Central Field has been unsatisfactory from a mining or sinking standpoint. Competent shaft sinkers and mechanics are at a premium. The class of labor used has to be trained in every particular, and good wages paid. Men may be shipped in, however, giving the advantage of greater sinking speed and the disadvantages of the company paying transportation and being subject to the dissatisfaction of this labor. The other solution of this problem is to reduce the manual question to one of machinery.

These three factors having been met, preparatory work is commenced, consisting of clearing and the boring of a test hole within 100 ft. of the shafts. Hard shales and sandstone formations are usually found, and as pockets of quicksand are liable to be met, this bore hole will make known the actual conditions.

Equipment is the next consideration. This is subject to: First, the intended size of the shaft or shafts, which in turn will determine the size and quantity of sinking material. Second, a time-limit factor, which means an added expenditure for time- and labor-saving appliances; there is also the question as to whether the two shafts are to be sunk simultaneously. Third, the depth of the shaft, upon which depends the nature, quantity and size of shaft lining and hoisting appliances. The size and number of temporary buildings and living accommodations are also controlled by this factor. Fourth, the nature of the strata encountered which will determine the method of drilling shot-holes, size of shaft lining and quantity of water to be pumped.

*Pembina Coal Co., Entwistle, Alta

A Typical Case Considered

Considering a typical example of the equipment for the sinking of two 14x18-ft. shafts, 500 ft. deep, the arrangement of the buildings as shown in Fig. 1, with their respective fixtures, will be taken in order.

The boiler room, engine room, two hoist rooms, supply house, wash house and office are all under one roof, thus making the most economical type of building.

It is suggested that the boiler house be equipped with a 100-hp. vertical boiler. This type is chosen because of the ease of transportation and erection, as well as the little space occupied. The company furnishing the boiler should also supply flanges, piping and connections to the generator, compressor, etc.; also an additional length of smoke-stack or some other blower arrangement. The air receiver can be placed in the boiler house, and the boiler tubes cleaned with a hose attachment.

Adequate preparations are to be made for coal storage and a two weeks' supply kept on hand.

In the engine room is placed a vertical air compressor, a generator and a switchboard. The compressor may be of the type supplied by the Peter Brotherhood, Ltd., of Peterborough, England, or its equal, with a capacity of 300 cu.ft. of free air per minute. This occupies a floor space of 3 ft. 9 in. by 6 ft.

The electrical unit is direct current, compound wound, having an output of 20 to 30 kw. at 220 volts, this voltage being chosen because of the ease of obtaining 110-volt lamps in western towns. The power from the generator is divided as follows: 20 hp. for pumps, 10 hp. for saw and 5 hp. for lights. A 40-hp. turbine (Kerr or its equal) is the most economical driving unit and occupies a little more space than the generator.

The switchboard is equipped with one 100-ampere switch, one 50-ampere switch, one 25-ampere switch (all of the double-pole type), one shunt rheostat, one 150-ampere circuit-breaker, and the necessary fuses, etc.

Installed in the hoist houses are two 8x10-in. reversible hoists, with loose drums 4 ft. in diameter, each bolted to a 7x7-ft. concrete foundation. The indicator on these machines should move 1 in. for each 10 ft. of rope travel, and a balanced type of throttle should be employed in place of the one usually supplied by the manufacturers. Signal code and hoist engineer's instructions should be conspicuously posted. A hammer and plate type of gong is a convenient signal appliance to use. A separate bell for the topmen as well as switches for sending return signals through a lamp cluster to

the sinkers are necessary. No other equipment should be placed in the hoist house.

A little thought proves profitable in equipping the wash room; at all events, it should be fitted with three shower baths, about 50 hooks and chains for the men's clothing, and steam heating coils.

The supply house and its fixtures are often a big question. Having no supplies in the field, it is hard to decide what material and repair parts will be needed for the sinking and construction operations. The following list is therefore given as a basis:

Tools—Round-nosed shovels, clay and miners' picks, steel wedges, 4- to 6-lb. hammers, 8-lb. sledges, axes, crow bars, hand saws, crosscut saws, wheelbarrows, monkey and pipe wrenches, steel levels, plumb bobs and line, files, chisels and small mechanics' tools, spare blasting equipment, cant-hooks and a few carpenters' tools, such as augers, wood chisels, etc.

Repair parts—Spare pump fittings and hose, drill fittings, engine fittings, dies for pipe machine and other spare machine parts.

General supplies—Steam and water packings, oils, two or three safety lamps, coal-oil torches, stable lanterns, carbide lamps and carbide, graphite and white lead, gage-glasses, pipe fittings, sheet tin and brass,

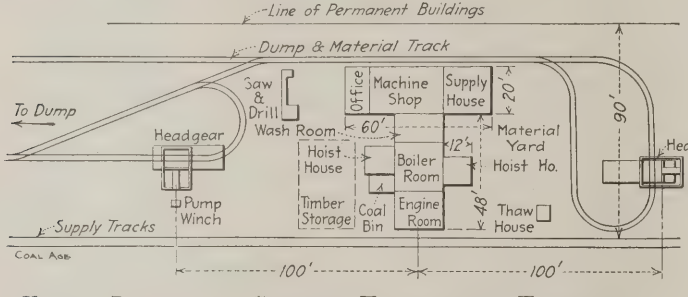

FIG. 1. LAYOUT OF SHAFTS, TRACKS AND TEMPORARY BUILDINGS

babbitt metal, lampwick, waste, iron wire, building paper, 2-in. to 6-in. nails, ½-in. to 1-in. manila rope and blocks for same, one 3-ton triplex block.

Stable supplies must also be stocked.

Iron and steel—Various sizes of bar iron, round, flat and square and drill steel.

A line of piping from ½ in. to 3 in. and a complete assortment of washers, nuts and bolts are required.

Sufficient oil-skins and gum boots should be stocked. Each man wears two suits which will shed water for about two weeks, if large quantities are encountered.

For the economical handling of the foregoing supplies, bins, shelves and boxes must be fitted in the supply house and convenient racks for piping and bar iron placed alongside this building. A desk and card index system for the use of the warehouse keeper facilitate the handling of the supplies.

Adjacent to the supply house is the blacksmith and machine shop. This is to be equipped with forge, anvil, grindstone, pipe and bolt machine, vise and a hand punch and shear. These tools can afterwards be used in the permanent shop. A 3-hp. gasoline engine or an electric motor will drive these appliances. Benches and cupboards should be installed for the carpenters and for small tools.

In the office there should be a drafting table, a master sinker's desk, two cupboards, a blackboard and a leanto desk for the shift bosses. A correspondence file and typewriter are necessary if this is the only office in the field.

A Convenient Headgear

Passing from this building to the headgear, the type usually built is unwieldy. In Fig. 2, a framework is shown which can be built by the blacksmith and erected over the shaft in a short time, and if necessary it is easily moved as a solid unit. The structure is self-bracing and is large enough to handle a 1-cu.yd. capacity bucket.

A self-dumping arrangement is shown in this figure, which works as follows: On the shaft doors, rails are fitted, and after the bucket is hoisted the doors are closed and the car pushed over the shaft top. The bucket is lowered into hooks and is dumped by the hoisting engineer slackening the cable. The empty bucket is then hoisted and the hooks pulled back out of the way of the crosshead. A good speed of hoisting can be attained by having two or three empties stored upon the tracks.

The tracks from each shaft to the dump are shown

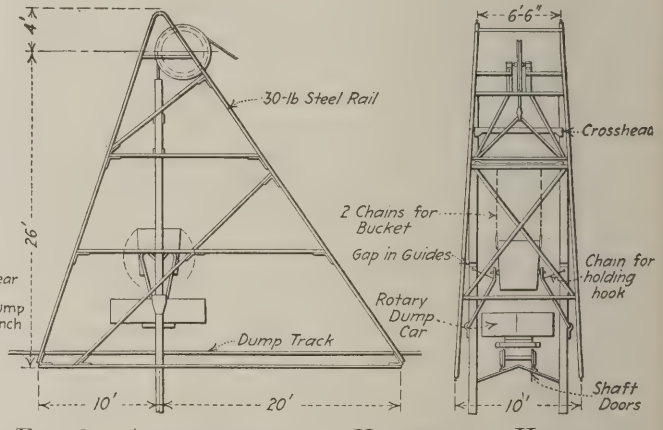

FIG. 2. ARRANGEMENT OF HEADFRAME, HOISTING BUCKET AND DUMP TRACK

separate. By this means, in the event of a derail or trouble with either shaft's dumping arrangement, the other is not affected.

Dump cars of 2 to 2½ cu.yd. capacity are used, and for this size of car, 25-lb. rails are necessary. For a haul of 300 yd., three dump cars per shaft are required. One horse per shift is necessary for each shaft. For these horses a stable must be erected.

A powder house must be supplied sufficiently large to accommodate 50 to 100 cases of explosive. A thaw-house 6x6 ft. has also to be built. It is sunk 3 ft. into the ground and steam heated with the exhaust from the turbine or compressor. Two cases of dynamite can be here stored, arranged in racks for thawing.

In the material yard is set a circular saw and a boring machine for wood working. The timber is so stored that it can be moved, sawed, trimmed and then loaded on a level track leading to either shaft with the least possible handling. With a few conveniences, such as a traveling cradle for use in sawing timbers, four or five carpenters can keep the two shafts supplied with sets.

A ditch to take away the discharge from the pumps is required and has to be figured on along with the other surface arrangements.

From the surface we pass to the shaft equipment.

The formation usually encountered in this district being soft sandstone or shale, churn drills will work well.

Air drills of the shaft-bar type have been tried, but they took too long for setting up and stuck in the holes, causing much delay. It is suggested that drills of the Jackhamer or Hardy Simplex type are much more speedy. Six to eight of these machines should therefore be purchased, with one or two extra lengths of hose.

For water removal, steam sinking pumps of the Cameron type may be used. Considerable delay, however, is experienced with this type of pump owing to sand and grit wearing away the valves, spindles and packing. As an alternative, two- or three-stage centrifugal pumps may be installed, driven by electric motors or steam turbines.

The pump and driving units are bolted between channel irons having a sheave wheel at the top, around which runs the rope for lowering or raising. A safety chain must be employed to prevent excessive swinging in the shaft. A winch may be placed at the shaft top, separate entirely from the main hoist, to raise and lower the pumps; this is advisable to prevent delaying operations. The suction hose should be of the inclosed-spring type and be marlin or chain wound to prevent cutting by flying rocks or by picks. Immediately above the pump, a hose 50 ft. in length is attached to form a flexible connection to the discharge pipe. This and the suction hose must be equipped with quick-coupling joints.

For lights in the shafts, two four-lamp electric clusters may be used, by the light of which all mucking and drilling operations can be carried on. For timbering, however, as well as for placing packing and lagging, two or three torches are necessary.

For placing the guides, a cradle consisting of a platform swung from four ropes should be supplied. This avoids much trouble in lining up and measuring.

Having thus chosen the equipment, the operation of sinking will be considered.

The first question in beginning actual sinking is the disposal of the men. For this size of shaft, eight men including the shift boss can be used to best advantage.

The Shaft Is Started Large

The shaft is started 18x22 ft., thus allowing for a 2-ft. shaft collar. For the first 10 ft., spading the dirt to a platform and then into the car will be the procedure, and with clay soil as usually found this can be continued until a depth of 20 ft. is reached, or until the hardpan upon which the concrete collar rests is encountered. It is seldom, however, that the surface soil will hold back a sufficient time to permit this depth without timbers.

The bearing timbers are then placed, each overlapping the sides of the excavation at least 4 ft. The whole set is lined up with a transit, and where bearing timbers cross one another they are securely bolted. The first shaft set is then swung immediately below this, skin tight to the bearers. Hanging bolts are placed and wrought-iron washers of ⅜-in. or ¼-in. plate used under the nuts. Cast-iron washers will break and ordinary washers pull through the timbers.

The second and third sets are hung on 5-ft. centers. Posts are put in the corners, buntons placed and center posts set, and the whole structure drawn tight with the hanging bolts. Lagging is then nailed on, the 2 ft. of room outside of timbers permitting this to be done. By means of brackets lined up accurately in place at the corners of the top set, the remainder of the sets are plumbed and wedged to the sides of the excavation, the surface soil being shored back with planking to prevent caving in. At least three plumb strings are to be used for lining up timbers, for although the sets are trimmed to templates, a slight discrepancy is noticed when notches are fitted together, and this can often be taken out in the plumbing.

Excavation is then resumed until another set of timbers can be placed. This is put in and the operation continued until a sufficient depth of shaft collar is reached, after which sinking is conducted with the neat size of 14x18 ft. below this depth.

The concrete for the collar is poured all around the shaft. Reinforcement is hung vertically on 18-in. centers and concreting continued until the surface is reached. The collar is built at least 2 ft. above surface level to prevent water running into shaft. The hoisting arrangements are now erected and the headgear set on the collar. When this is completed, the sinking is continued, but no blasting should be permitted until the shaft is sufficiently far below the collar so as not to injure same.

For shooting, it will be found most economical to drill eight 6-ft. holes around the sides of the shafts and four 8-ft. sump holes at an angle of 20 deg. from the vertical. More muck can be hoisted and faster footage made with this depth of holes than if they had been drilled 10 or 12 ft. deep. The constant tramping of the men packs the shale so hard that pick work has to be resorted to, and this takes time. When the holes are finished, six men go to the surface, while the shift boss and a helper stay down to charge the holes. When this is done, they go to the surface and the shots are fired. The shaft is then examined, the débris scraped off the timbers and the men resume mucking. When sinking has reached the depth of 100 ft., it is advisable to make preparation for blowing out powder smoke. This can be done when air drills are used, by opening the manifold at the foot of the air pipe, controlling the same with a valve on the surface.

The carpenters should have a set of timbers ready trimmed, lagging sawed to length and wedges and packing handy when the dirt is mucked out the required distance for the timber. This set is then lowered, lined up, wedged and lagged in place. The strata will not usually hold back sufficiently long to enable the timbers to be built up on hitches, therefore sets are placed as soon as sufficient room is made. A clevis should be used in lowering timbers, and a definite method of lowering wall plates, end plates, etc., understood between the shift boss and the topmen. The center bunton is usually left out in the last set of timbers, so that the bucket can be swung to the shaft side.

It is possible with a well trained crew to timber and lag a shaft set in 3 hr., although if large holes are made inside the shaft, the packing of same will take much longer.

Hitch timbers are to be placed every 80 to 100 ft., and if possible these should rest on a hard pan or rock strata. Heavy shots must not be fired immediately below a hitch set, and the shaft set under this should be particularly well wedged and packed.

Water rings are cut in the shaft at every spring encountered, and the water piped from ring to sump, preventing excessive spraying in the shaft. A ring must be placed over the door set leading to the coal seam; this prevents water from traveling back over the entry timbers.

The door set should be 12 ft. in height and one side of the shaft should be beveled off to permit 30-ft. lengths of rail to enter the mine.

Loose Leaf

FIG. 3. FORM OF DAILY COST LOG

Before operations in the seam are commenced, sinking should be continued down to the bottom of the sump; this is timbered and the last shaft set placed on the bottom and securely wedged and blocked underneath, so that when the landing timbers are placed upon it, the drop of the cage does not affect it.

A FAIR STANDARD OF SPEED

This gives the general operation, and it is considered good progress if a round of holes is shot, mucked and one set of timbers placed in three shifts.

The estimated number of men necessary for sinking two shafts will be as follows: One master sinker, one clerk, one warehouse keeper, four 12-hr. shift bosses, forty-two 8-hr. muckers, two 12-hr. pumpmen, four 12-hr. hoist engineers, two 12-hr. firemen, four 12-hr. topmen, eight 12-hr. dumpmen, including drivers; five 10-hr. carpenters, two 10-hr. blacksmiths and two 10-hr. laborers.

It is necessary that a good system of cost keeping be used and followed to prevent excessive expense for labor and supplies.

Forms as shown in Fig. 3 are suitable for keeping these costs and will enable a daily log of the sinking operations to be kept.

ESTIMATED COST OF EQUIPMENT REQUIRED

Boiler House, 20x24 Ft.	
Vertical 100 h.p. boiler	$2,000
Concrete foundation	80
Building and erection	500
Air receiver	120
	$2,700
Engine Room, 20x18 Ft.	
Vertical compressor	$1,800
Turbine and generator	1,200
Concrete foundations	150
Building and erection	300
Erection of engines	250
	$3,700
Hoist Houses, Two, 12x15 Ft.	
Two hoists	$3,000
Foundations	100
Buildings and erection	300
	$3,400
Wash-House, 12x20 Ft.	
Building and erection	$150
Equipment	200
	$350
Supply House, 20x20 Ft.	
Building and erection	$300
Equipment	200
Tools and supplies	1,500
	$2,000
Blacksmith Shop, 20x30 Ft.	
Building and erection	$500
Blacksmith's tools	130
Peerless drill	80
Grindstone	30
Pipe threading machine	500
Punch and shear	70
Shafting	50
Motor	150
Extras	100
	$1,610
Foreman's Office, 20x10 Ft.	
Building and erection	$300
Engineering equipment	500
	$800
Outside Equipment	
Two headgears	$1,000
Ropes, ¾-in. non-twist	500
Dump arrangements	500
Tracks	500
Dump cars	1,000
Stable	300
Powder house and thaw house	150
Circular saw and motor	250
Boring machines	100
Gearing, etc.	100
	$4,400
Shaft Equipment	
Air drills and hose	$1,600
Two centrifugal pumps with motors	2,000
Pump winches and equipment	500
Crosshead and cradle	250
Water tank or reservoir	250
	$4,600
Summary	
Boiler House	$2,700
Engine room	3,700
Hoist House	3,400
Wash-house	350
Supply House	2,000
Blacksmith Shop	1,610
Office	800
Outside equipment	4,400
Shaft equipment	4,600
Boarding House	1,000
Total	$24,550

Say $25,000 would be necessary for equipment, and a fair charge to the shafts for this item would be $8 per foot.

The cost of timber would approximate $10 per foot, thus bringing the cost of dead supplies to $18 per foot.

	Per Foot
Explosives will cost about	$4
Coal	6
Labor	50
Making a total estimated cost per foot of shaft of	$78

The accompanying table shows a rough estimate of the cost for equipment and material required for such sinking operations as have been above described. It will of course be understood that local conditions may greatly alter various figures here presented. It is believed, however, that the estimate here given is a fair one and reasonably represents the majority of cases.

Plant of the Glen Alum Coal Co.

By W. J. Darley*

SYNOPSIS—This article describes the plant in which is installed what is believed to be the longest double-chain retarding conveyor in use at the present time.

Located on a short branch of the Norfolk & Western R.R., about 3½ miles north of Genalum Junction, in Mingo County, W. Va., in one of the most beautiful ravines draining to Tug River, is the newly completed plant of the Glen Alum Coal Co.

Although several distinct coal beds underlie the company's property, only the most promising one is at present being worked. This is 6 ft. thick and the outcrop on the mountain side has an elevation of 1564.25 ft. above sea level. The elevation of the railroad tracks at the tipple is about 1089.25 ft., so that the coal must be lowered approximately 475 ft. from the coal bed to the coal car.

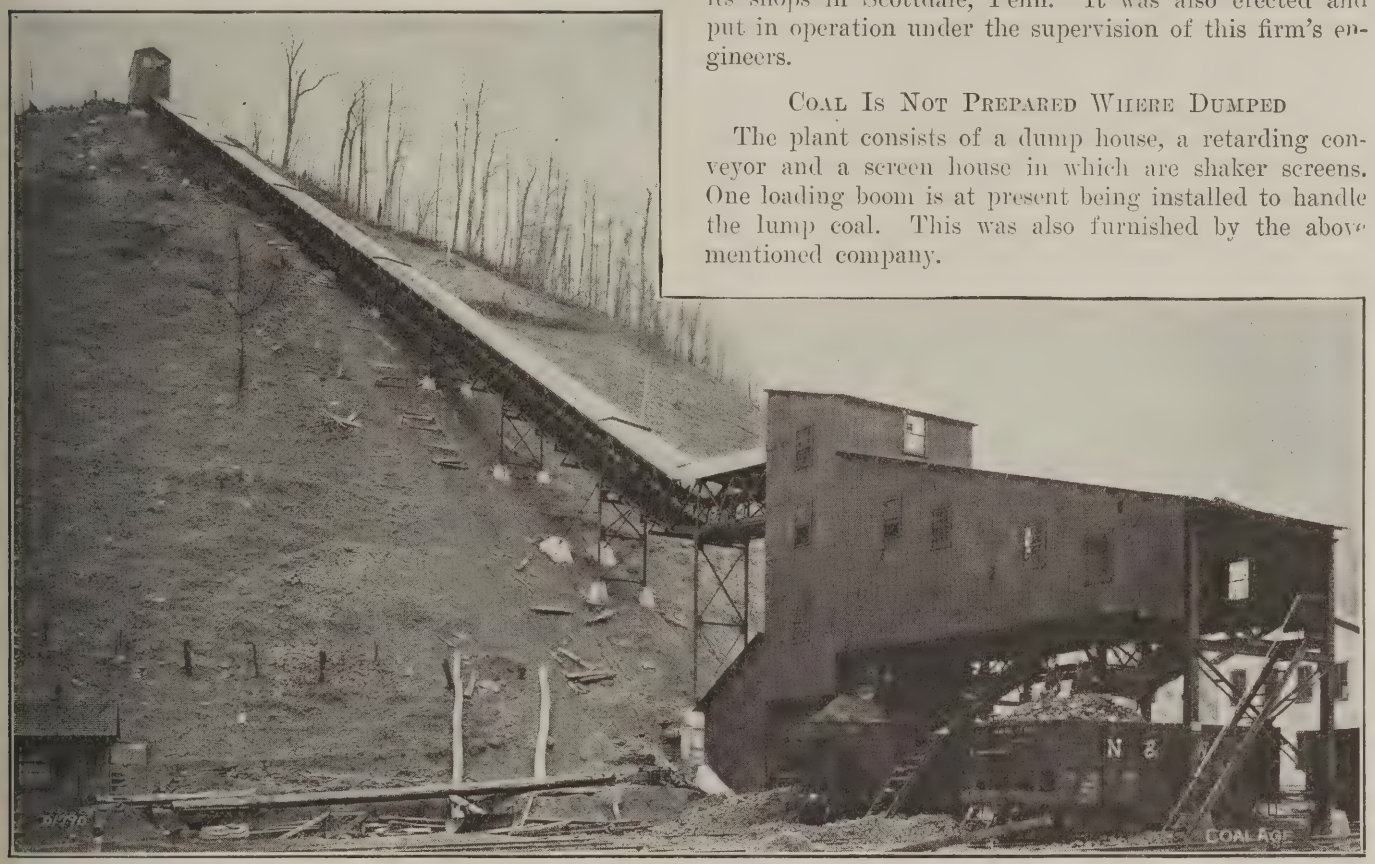

Fig. 1. General View of Dump House, Conveyor and Tipple

The coal received at the drift mouth in two-ton cars is transported by Jeffrey locomotives down a tramroad with a 2½% grade which skirts the mountain side for almost a mile to the dump house. Opening the drift mouth almost a mile away from the tipple served a double purpose, first bringing the opening as near as possible to the center of the coal field, and second, in reducing the vertical distance between dump house and preparation plant, consequently lessening the distance which the coal has to travel between the pit cars and the railroad cars.

As this company has had previous experience with a wooden tipple burning down and throwing the whole operation into idleness the present building is constructed fireproof. The only wood entering into this structure is a few nailing strips, the necessary platforms around the screens and the treads on the stairs. It was considered advisable to employ wood treads, as these give a surer foothold to the workmen than those constructed of steel or iron.

The dump house and entire coal-preparation plant was built by the Scottdale Machine & Manufacturing Co. at its shops in Scottdale, Penn. It was also erected and put in operation under the supervision of this firm's engineers.

Coal Is Not Prepared Where Dumped

The plant consists of a dump house, a retarding conveyor and a screen house in which are shaker screens. One loading boom is at present being installed to handle the lump coal. This was also furnished by the above mentioned company.

The dump house is 16x28 ft. in dimensions. It is provided with a 3-in. oak floor, and the structural steel frame is covered with corrugated sheeting. Cars are lowered one at a time from the loaded trip, pass through a kick-back dump and return to the empty track by gravity. The contents are deposited in a hopper of 18 tons capacity, from whence the material is sent to the retarding conveyor by a reciprocating plate feeder making approximately 30 strokes per minute. The length of the stroke may be varied from 2 to 18 in. to suit any desired capacity.

The feeder is driven by a 7½-hp. Westinghouse direct-current motor, which, together with the driving machinery, is mounted in a steel frame made of heavy channels and plates.

The angle of inclination of the retarding conveyor is 30 per cent. and the linear speed 100 ft. per min. The conveyor trough is made up of ¼-in. steel plates, is 3 ft. 2 in. wide and 12 in. deep. The links of the double

*Scottdale Machine & Mfg. Co., Scottdale, Penn.

conveyor chain are made of ¾x3-in. strap steel containing 0.004 per cent. of carbon. These are joined by 1½-in. pins pitched 24 in. apart, upon which revolve rollers 4 in. in diameter with a 2-in. face. Between the two strands of chain thus constructed, ¼-in. pressed steel flights 36 in. wide and 12 in. deep are spaced 4 ft. apart. A view of the lower end of this conveyor may be seen in Fig. 2.

The Longest Conveyor of Its Kind

While it will be readily conceded that conveyors of the rope and disk or of the monobar type are in existence much longer than this one, it is believed that this is the longest retarding conveyor of its kind in existence, measuring 712 ft. from center to center of the sprocket wheels. The normal capacity of the apparatus is 300 tons per hour, but observations taken on the second day after the conveyor was put in operation showed that this capacity might be increased approximately 65 per cent. Upon this occasion a 50-ton railroad car was loaded with run-of-mine coal in 6 min. without overtaxing the machinery.

The coal is received on the lower strand of the conveyor from the reciprocating feeder above mentioned, and brought down the hill with the least possible breakage and discharged to the shaker screen or to the run-of-mine bypass chutes.

In order to prevent the chain from sliding down the conveyor and possibly wrecking in case the former should break, safety dogs are located every 42 ft. upon the top strand. It is impossible for this part of the chain to run back more than 12 in. before one or all of these dogs automatically take hold, and each one is made sufficiently strong to hold the entire upper part of the conveyor chain.

The dogs are so constructed as to be automatically raised as each roller passes under, but the instant the direction of travel of the chain is reversed the rollers come in contact with and are held firmly by the dogs until the chain can be repaired. The lower portion or "part" of the conveyor travels on $3\frac{1}{2}x\frac{5}{16}$-in. track bars over which is placed an angle-iron guide to prevent the chain from buckling and piling up in case it should break.

The Details of the Conveyor Drive

The conveyor is driven by a 50-hp. Westinghouse direct-current motor, the voltage being 230 and the speed 750 r.p.m. The power is transmitted through three sets of reduction gears, of cut steel, semisteel and cast steel, respectively. The head sprockets are also of cast steel, while the tail sprockets are of cast iron. Each of these carries 7 teeth of 24-in. pitch and are 4 ft. $7\frac{5}{16}$ in. in diameter. The head shaft is 7 in. in diameter and runs at 6.8 r.p.m. This machinery is mounted on a heavy structural frame which prevents the running parts from getting out of line.

The foundation for the driving machinery required about 275 cu.yd. of concrete, which is anchored to the bedrock by a number of steel dowel pins, which were placed in holes drilled in the rock before the concrete was poured. All of the important foundations for the conveyor were anchored in a like manner.

The frame in which the conveyor is carried is 8 ft. wide and 8 ft. high and is built up of angle trusses 48 ft. 6 in. long. It is covered on top with No. 20 corrugated ingot-iron sheeting, while provisions are made for closing in the sides in the future should this be found necessary. In order to prevent the snow from sliding down the 700-ft. roof of this conveyer and wrecking the screen house, deflectors are spaced about 120 ft. apart, which divert snow or rain water over the sides of the conveyor roof. Steps are provided upon either side of the conveyor throughout its entire length.

Three Expansion Joints Are Provided

On account of the extreme length of the conveyor and frame, it was necessary to provide some means of taking care of the expansion and contraction, which amounts to about 3 in. for each 100 deg. change in temperature. The conveyor housing was accordingly made in three sections, the upper end of each being anchored firmly in place, while the lower is allowed to go and come, the joints being made in such a way as to allow the entire structure, including the roof, to move freely for a distance of 2 in. at each expansion joint.

As the coal will naturally pile up behind the flights on a slope of 30 deg. and thus not discharge in an even and constant stream, the lower end of the conveyor was made on an angle of 5 deg. for a distance of approximately 30 ft. This allows the material to distribute itself to

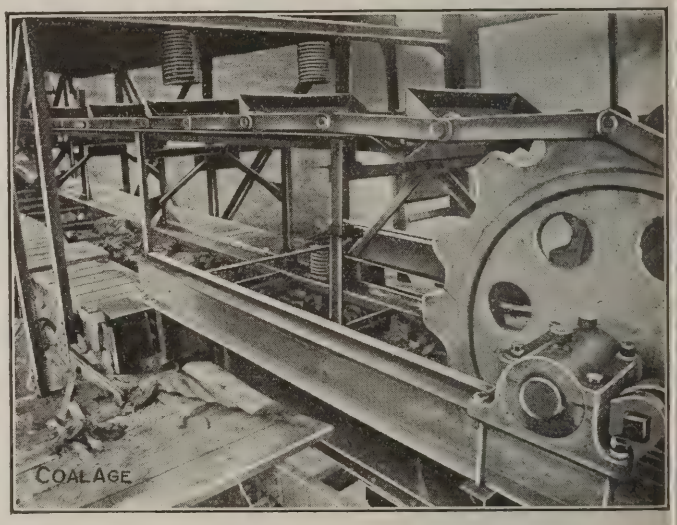

Fig. 2. Lower End of Conveyor, Showing Tail Sprocket

an even depth, thus insuring a constant stream into the shakers.

The shaking screens, which are carried on rollers, are 6 ft. wide and double decked, the upper deck alone being perforated. No veil plates are used, the screens being so designed that run-of-mine, lump or a mixture of lump and egg coal may be loaded on the lump track. Similarly, slack and egg or egg alone may be loaded on the egg track, and run-of-mine or slack on the slack track. In order to reach the slack track, however, the run-of-mine is sent through a bypass chute independent of the screening machinery. It is thus unnecessary to operate the screens when loading run-of-mine coal.

A Separate Structure Supports the Screens

A separate steel frame not connected in any way with the housing or conveyor structures supports all the oscillating parts. This segregates vibration to the supporting structure, there being no possibility of it being communicated to the screen house proper.

The screen motor is controlled by the shaker man, and the conveyor and feeder motors are so wired that by pressing a button he may stop either of these machines. These latter cannot be started again until an electric current in the circuit-breaker is switched on by the shaker attendant. The conveyor should always be started before the feeder, and the motors are so wired as to render any other procedure impossible.

This firm manufactures its own electric energy at a power plant near the old mine about one mile farther up the hollow from the plant in question. The expectation is, however, that a large new power plant as well as a repair shop will be constructed in the near future.

The equipment above described was installed under the direction of Maurice Watts, general manager of the company, to whom I am indebted for the general data above given.

The Increased Coal Output of Arkansas

The production of coal in Arkansas in 1913, according to E. W. Parker, of the U. S. Geological Survey, was 2,234,117 short tons, valued at $3,923,701, as compared with 2,100,819 tons, valued at $3,582,789 in 1912, or a gain of 133,288 tons in quantity and $340,912 in value. The increased production is attributable to a larger railroad consumption, caused partly by a decrease in the supply of fuel oil and partly by increased business. This was offset to some extent by decreased domestic consumption, particularly in Texas, owing to an increased use of natural gas in that state.

The prolonged drouth in August and September had an adverse influence on coal production, as it cut down the wheat crop in Kansas and the cotton crop in Oklahoma and Texas. Transportation facilities were improved over those of previous years, and a reduction in freight rates put into effect in the latter part of the year is expected to have a beneficial effect on the industry by enabling larger quantities of coal to be shipped to the Northwest, where Arkansas semi-anthracite has established a market that has already to some extent replaced West Virginia smokeless coal. The conditions at the close of 1913 represented a more hopeful outlook for the future than has existed in Arkansas for several years.

The number of men on strike for one cause or another in 1913 was 1321, or a little more than one-fourth of the total number employed, while the average number of working days lost by each man on strike was 27. The average quantity of coal produced per man was 480 tons, as against 463 tons in 1912. According to the Bureau of Mines there were 12 fatal accidents in 1913, or just double the number occurring in 1912. The death rate per thousand was 2.58, while 186,176 tons of coal were mined for each life lost. In 1912 the death rate was 1.3, and the coal produced for a life lost was 350,137 tons.

Weak Props That May Cause a Fall

The Purchase of Coal on Specifications--II

By F. R. Wadleigh*

SYNOPSIS—In this second installment, the fallacy of emphasizing the importance of the moisture and volatile content is taken up. Specifications are often exceedingly rigid on these points, when, as a matter of fact, they are either beyond control of the producer or are insignificant insofar as actual heat values are concerned. Ash and clinkers are also discussed, the latter in considerable detail.

Taking all of the different properties and constituents that may enter into coal specifications, a discussion of the advisability and practicability of their use will be made, eliminating every item not absolutely pertinent. It is hoped in this way to work out contract specifications that are easy to understand, practical in operation and fair to both the seller and buyer.

Moisture

The determination of moisture and its part in coal specification demand careful consideration, as there are some differences of opinion on the subject.

The actual heat loss due to moisture as shown by analysis has often been greatly exaggerated. In the first place, there is nearly always a large possible variation in moisture, which sampling cannot always correct. Next, the coal when it reaches the furnace is almost always drier than when it is unloaded. Then the heat necessary to vaporize the moisture and raise it to flue-gas temperature will lower the percentage heating value of the coal only about 0.1 of one per cent. of the moisture in the coal.

For these reasons, the percentage of moisture allowed in a specification contract should be sufficient to take care of all these various items.

For instance, the contract (290,000 tons) for the coal purchased by the London, England, County Council calls for an allowance of 10 per cent. moisture. In case it runs below this, the quantity of coal paid for is increased beyond the actual weight by a percentage equal to the decrease in moisture; but when the moisture runs over 10 per cent., the amount of coal paid for is decreased in a like manner. Moisture is a factor often impossible to control, as when coal is wet by rain or snow after it has been shipped from the mines.

Volatile Matter

The volatile matter of coal is made up principally of:

1—Hydrocarbons of varying composition.

2—A part of the total sulphur.

3—Nitrogen.

4—Combined water.

It should also be remembered that a part of the volatile matter is noncombustible, the amount ranging from 1 to 15 per cent. of the coal.

Specifying a limited percentage of volatile matter and basing the premiums or penalties on such percentage are only justified where the question of smoke enters in.

The method of determining the percentage of volatile matter in coal is an arbitrary one, and the accuracy of the result depends largely upon handling conditions. Two different chemists, in different laboratories, both trying to follow the same method, may, according to Sommermeier, easily obtain results differing 2 to 3 per cent. But a good chemist working in a fixed way with the same crucible, same height of gas flame and same burner, can obtain duplicating results within a few tenths of 1 per cent., and the results, on coals of approximately similar nature, should be comparable within 1 per cent.

"White's Gas and Fuel Analysis" says: "Most of the volatile material (evolved from coal) is a decomposition product where the amount varies with the rate of heating, the maximum temperature attained, the character of the flame, the sizes of the crucible and other conditions."

Messrs. Fieldner & Davis, chemists of the U. S. Bureau of Mines, investigating the question of volatile matter in coal, found that using the ordinary water gas at the Washington laboratory gave a maximum temperature of 970 deg. C. inside the crucible. This was 120 deg. higher than they could obtain with Pittsburgh coal gas or natural gas. The conclusions formed from their experiments are as follows:

> Two laboratories are likely to vary 2 per cent. in volatile matter, both using the official method (of 1899). The percentage of volatile matter obtained from the same sample of coal varies with the temperature and rate of heating. This is not sufficiently defined by height of flame. Temperatures ranging from 160 deg. C. to 890 deg. may be obtained with a 20 cm. natural gas flame, when the gas pressure is varied from 1 to 13 in. of water; variations of 2 per cent. volatile matter are thus produced. Differences in height and sizes of burner influence results from 0.3 to 1.5 per cent. Polished crucibles become hotter and yield about 1 per cent. more volatile matter than dull gray ones.
>
> Laboratories using natural gas are apt to get results on volatile matter that are considerably lower than those using coal gas, unless the following precautions are observed: (1) Gas should be supplied to the burner at a pressure of not less than 10 in. of water. (2) Natural-gas burners admitting an ample supply of air should be used. (3) Gas and air should be regulated so that a flame with a short, well defined inner cone is produced. (4) The crucibles should be supported on platinum triangles and kept in a well polished condition.

Volatile Matter in Specifications

In 1913, the committee on coal analysis, appointed by the American Chemical Society, made its report and recommended the following alternate methods for determining volatile matter in coal. One of these two methods should be specified in all coal specifications where penalties or premiums are enforced on percentage of volatile matter:

> It is recommended that for volatile matter determinations a 10-gram platinum crucible be used having a capsule cover, that is, one which fits inside of the crucible and not on top. The crucible with 1 gram of coal is placed in a muffle maintained at approximately 950 degrees C. for seven minutes. With a muffle of the horizontal type, the crucible should not rest on the floor of the muffle but should be supported on a platinum or nichrome triangle bent into a tripod form. After the more rapid discharge of the volatile matter, well shown by the disappearance of the luminous flame, the cover should be tapped lightly to more perfectly seal the cover and thus guard against the admission of air.
>
> One gram of coal is placed in a platinum crucible of approximately 20 c.c. capacity (35 mm. in diameter at the top and 35 mm. high). The crucible should have a capsule cover which will readily adjust itself to the inside upper surface of

*Consulting engineer, 426 Real Estate Trust Bldg., Philadelphia, Penn.

the crucible. The crucible is placed in the flame of a Meker burner, size No. 4, having approximately an outside diameter at the top of 25 mm. and giving a flame not less than 15 cm. high. The temperature should be from 900 degrees to 950 degrees C. determined by placing a thermocouple through perforated cover which for this purpose may be of nickel. The junction of the couple should be placed in contact with the center of the bottom of the crucible. Or the temperature may be indicated by the fusion of pure potassium chromate in the covered crucible (fusion of K_2CrO_4, 940 degrees C.). The crucible is placed in the flame about 1 cm. above the top of the burner and the heating is continued for seven minutes. After the main part of the gases have been discharged the cover should be tapped into place as above described.

For lignites a preliminary heating of five minutes is carried out, during which time the flame of the burner is played upon the bottom of the crucible in such a manner as to bring about the discharge of volatile matter at a rate not sufficient to cause sparking. After the preliminary heating the crucible is placed in the full burner flame for seven minutes as above described.

The accuracy that should be obtained by a reliable chemist is shown in the accompanying table, taken from the report to the American Chemical Society of its committee on coal analysis, 1913:

	Allowable Variations, %	
	Same Analyst	Different Analysts
Moisture, under 5%	0.2	0.3
Moisture, over 5%	0.3	0.5
Volatile matter, bituminous coals	0.5	1.0
Volatile matter, lignites	1.0	2.0
Ash, no carbonates present	0.2	0.3
Ash, carbonates present	0.3	0.5
Ash, more than 12%	0.5	1.0
Sulphur, in coal	0.05	0.1
Sulphur, in coke	0.03	0.05

Further, a variation in volatile constituents affects the manner and rate at which the gases are given off during combustion, and two coals varying in volatile content may act in the same manner on distillation in a furnace or coke oven. On the whole, the composition of the volatile matter of coals is so varied and our knowledge of some of the constituents so incomplete that it is advisable, as a general rule, to avoid the use of it in coal specifications.

We must call attention here to the fact that, when considering the effect of volatile matter on combustion, especially with regard to smoke production, it is not always the *quantity* that is important, but also its composition. There is always some incombustible volatile matter in coal, such as carbon dioxide, water and nitrogen, that lowers its heating value; varying percentages of the hydrocarbons also affect the heating value and tendency to produce smoke.

Oxygen in combination is also detrimental to the heat of combustion, diluting and rendering ineffective the equivalent combining weight of carbon, hydrogen or sulphur. According to Dr. David White, oxygen has about the same anticalorific effect that the same percentage of ash would have. He says:

"In other words, with respect to their efficiency as fuels, oxygen is an original impurity in coals, which improve according to the extent of its removal." (U. S. Geological Survey Bulletin, 382.)

Ash

The ash of a coal consists of the ash content of the vegetable matter from which the coal was formed and the earthy matter from the strata above, below and in the coal, together with the various substances deposited by water running through the coal seams. Analysis of the ash will yield, in varying quantities, silica, alumina, oxides of iron, lime, magnesia, potash, soda, sulphuric and phosphoric acids.

The following tables give: (1) Ash analyses as showing the variations in constituents of ash; (2) analyses giving also the fusing point of the ash:*

ASH ANALYSIS OF SOME AMERICAN COALS

	Pocahontas	New River	Reynoldsville	Fairmont	Pittsburgh	Ziegler

Clinkers

The amount and kind of clinker is of such importance in plant operation that it seems obvious all specifications for coal purchase should contain some provision for handling the question, omitting restrictions as to the firing methods used.

Ash Analysis—To analyze the ash is not always practical, for several reasons:

1st—It will not tell us with any certainty whether a coal will clinker readily or not, under furnace conditions.

2d—Such analysis is too costly and too difficult to make.

3d—It is difficult, if not impossible, to get an average sample of the ash.

Color of Ash—The color of the ash has often been considered as an indication of its fusibility. A reddish or iron-colored ash was supposed to indicate a clinkering coal, and a white or yellowish color, the reverse. This, however, is not always true, as some coals with a reddish colored ash do not clinker readily and some white-ash coals do.

Actual Burning of Coal—This, of course, will always tell whether any coal will clinker, and the nature of the same; but to determine on a standard for specifications from such tests would obviously be impossible.

Ash-Fusing Temperature. Determination of, as Indicating the Clinkering Property of a Coal—The formation of clinkers is due to the temperature of the fuel bed reaching the temperature at which the ash will fuse; or it depends upon the fusing point of the ash and the temperature to which it is subjected. This question as applied to coals was first taken up actively on a commercial basis as far as I know about five years ago, the Fuel Testing Co., of Boston, being the pioneers in the movement. This company, in its Bulletin No. 3, published in 1910, on "Clinkers and the Fusing Temperature of Coal Ash," gave some findings and results from its experiments. It had at that time the only laboratory in this country equipped to do this work on coal ash. Since then, a few other chemists have started similar work, and the U. S. Bureau of Mines is now experimenting along these lines, although as yet it has not given out any results, and does not include the ash-fusing temperature in any of the government coal specifications. The value to the consumer of accurate information on

*Rogers & Auberts "Industrial Chemistry," page 439.

the clinkering of coals can hardly be overestimated, and is of vital importance in steam-plant operation. The amount of clinker made is not of so much importance as is its nature and the temperature at which it is formed. A coal of great purity as regards total ash often has a low fusing point and may make a thin, sticky clinker that is difficult to remove from the grates. This same coal may also have a high B.t.u. value, and yet give unsatisfactory results in burning. It is also a fact that coals with the same amount of ash may have entirely different clinkering qualities.

As a matter of actual fact, the coals that give the most trouble with clinkers are usually quite low in total amount of ash. As the clinker is merely a mass of melted or fused ash, it follows that the ash must have a fusing point at which it begins to melt. If we know this point of fusion and the average temperature to which the ash is to be exposed, we have an accurate means of determining the liability of various coals to clinker under the same furnace and firing conditions.

There is often a great difference in the quantity and quality of clinkers formed from different coals, either from different seams or from the same seam, or sometimes in different shipments of coal from the same mine. Such difference must be due to or dependent upon the temperatures at which the ash of the different coals will fuse.

For further data on the clinkering of coals, see *Engineering News*, Vol. 64, No. 23; COAL AGE, Vol. 1, No. 37; Bulletins Nos. 3 and 5, Fuel Testing Co., Boston, Mass.; COAL AGE, Vol. 2, pages 862, 111, 218.

In the use of the ash-fusing point in coal specifications, it must be remembered:

1st—That the amount of ash fused increases rapidly as the fusing point falls below 2500 deg. F.

2d—That with low-fusing temperatures, the character of the clinker is altered, so that more grate-surface is covered per pound of clinker; in other words, the clinkers will run and spread more rapidly and be harder to remove.

Next in importance to buying the kind of coal best suited to the conditions under which it is to be burned is the ash and clinker question, as the amount present seriously affects the efficiency, capacity and operation cost of the steam plant. No matter what kind of coal is bought, low ash means high B.t.u. value, and conversely. It is a dead loss as far as fuel value is concerned, and when present in a certain proportion it makes the fuel useless.

Summing up the bad effects of ash, we have:

It lowers the heating value in the furnace, as its temperature must be raised to that of the fuel bed.

It must be removed at a more or less high temperature, carrying with it heat, together with some combustible, the amount depending upon the grate and furnace design, working of boiler and skill of the fireman.

A greater percentage of ash increases operation costs and decreases the fireman's output of useful work, making this work harder, and causing dissatisfaction.

It decreases possible boiler capacity and efficiency, by clogging up the grates, heating surfaces and furnace settings, thus retarding combustion.

It increases the wear of grates, furnaces and ash-handling apparatus.

The nature of the ash, whether it has a low or high fusing temperature, and the character of the fused ash or clinkers have more to do with plant capacity and efficiency than any other single element in coal; in fact, more than all the others put together, when considering coals of similar nature.

Knowing the ash-fusing temperature of a coal, we do not need to bother about any analysis of the ash, which at best would only give an approximate idea of its behavior. The ash-fusing determination, on the other hand, gives us definite information which can be embodied in coal specifications and made a basis for payment. To illustrate, two tables of ash-fusing determinations are given below, the first taken from the Fuel Testing Co.'s Bulletin No. 5, on Fusing Temperature of Coal Ash, and the second from my own practice, all of the determinations in the latter, with two exceptions, having been made by the same chemist:

	Character of Coal	Fusing Temperature of Ash Deg. F.	Percentage of Ash in Coal	Percentage of Sulphur in Coal	Percentage of Iron Oxide in Ash

To apply these figures of ash-fusing temperatures to actual furnace temperature determinations, we give the following figures showing observed furnace tempera-

Coal	Furnace Temperature[1] Average	Highest	Lowest
High volatile (53 tests)	2470	2864	2091
Low volatile (12 tests	2435	2785	2059

[1]Degrees Fahrenheit.

All of the above temperature observations were taken at the rear of the combustion chamber, with a Wanner optical pyrometer, and are therefore probably lower than the actual temperatures, especially with low-volatile coals and when running with low boiler capacity. With low-volatile coals also the hottest point will be closer to the grates.

Clinkers are the *bête noire* of the power-plant operatives; a badly clinkering coal will add 50 per cent. to the labor of the fireman and discourage any efforts at economical firing. It may be said, however, that clinkering is often due to the misguided or careless methods of the fireman himself, when he allows his fire to burn in holes and uses the slice bar continually raising the clinkers on the grates to the hottest zone of the fire and lowering the greatest heat down to the grates through holes in the fire.

Extracts from a Superintendent's Diary

It is discouraging to think of the amount of trouble that two or three miners with a grouch can stir up if they are possessed of a little imagination and go about the task with enough determination. I remember an instance where they nearly shut down a mine by systematically stealing powder from their "buddies" until everyone had become disgusted by the annoyance and threatened to move to another camp. Almost the same result was achieved by swapping miners' checks on the tram cars, only this resulted a little more seriously as several of the victims resorted to fist fights before they found out that the ones whose weights were running long were profiting innocently.

Just now we are taking part in a bitter dispute with one of the railroads that uses our coal for passenger locomotive service because some of our men, for reasons best known to themselves, have been sending out cars half loaded with rock so cleverly topped that they have passed through the tipple without being noticed.

Eventually it will transpire that the two or three men who are at the bottom of this planned the ruse very carefully, even to choosing a critical time when the particular railroad effected would be sure to receive the coal intended for them. And if we succeed in placing the blame we can only discharge the offenders.

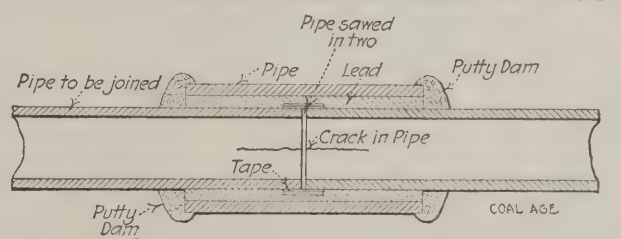
The motive department of the railroad notified our general office that several of their passenger locomotives had "gone dead" because of inferior coal received from our mine and demanded an immediate inspection of our entire plant and loading facilities. They would welcome an opportunity to cancel our present contract, since the price of coal is lower now than it was when the contract was made. The plotters were probably aware of that fact also.

During the next few days while everything about our tipple is inspected, each one of our weigh-bosses, dumpers, slate pickers and car trimmers will perform his task with fear and misgiving, knowing full well that a shut down at the present time means short rations for all to say the least.

Their anxiety is not without foundation; during a similar dispute with a railroad several years ago I learned that it is not an easy matter to uphold the mine's side of a controversy where quality of coal is the cause of complaint, because although it would seem easy enough to describe quality of coal accurately in a contract, as a matter of fact it is almost impossible to choose words that will prove binding if one of the party really desires to renege.

And to think that this sea of troubles can probably be traced back to some inexcusable misunderstanding originating in a short word passed between a commissary clerk and one of the miner's daughters, or to a gruff answer from a check clerk to a miner who thought he had a certain amount on the payroll when in reality he had nothing.

There's one consolation, however, in all this grim performance, and that is we will get rid of the guilty parties, because even if we don't succeed in finding them out they won't be able to resist for long the temptation to crow to some of their "buddies" about what they did. That's better than having them around indefinitely with a festering grudge, liable at any time to incite our entire community into a strike.



Repairing a Split and Dented Pipe

By N. G. Near

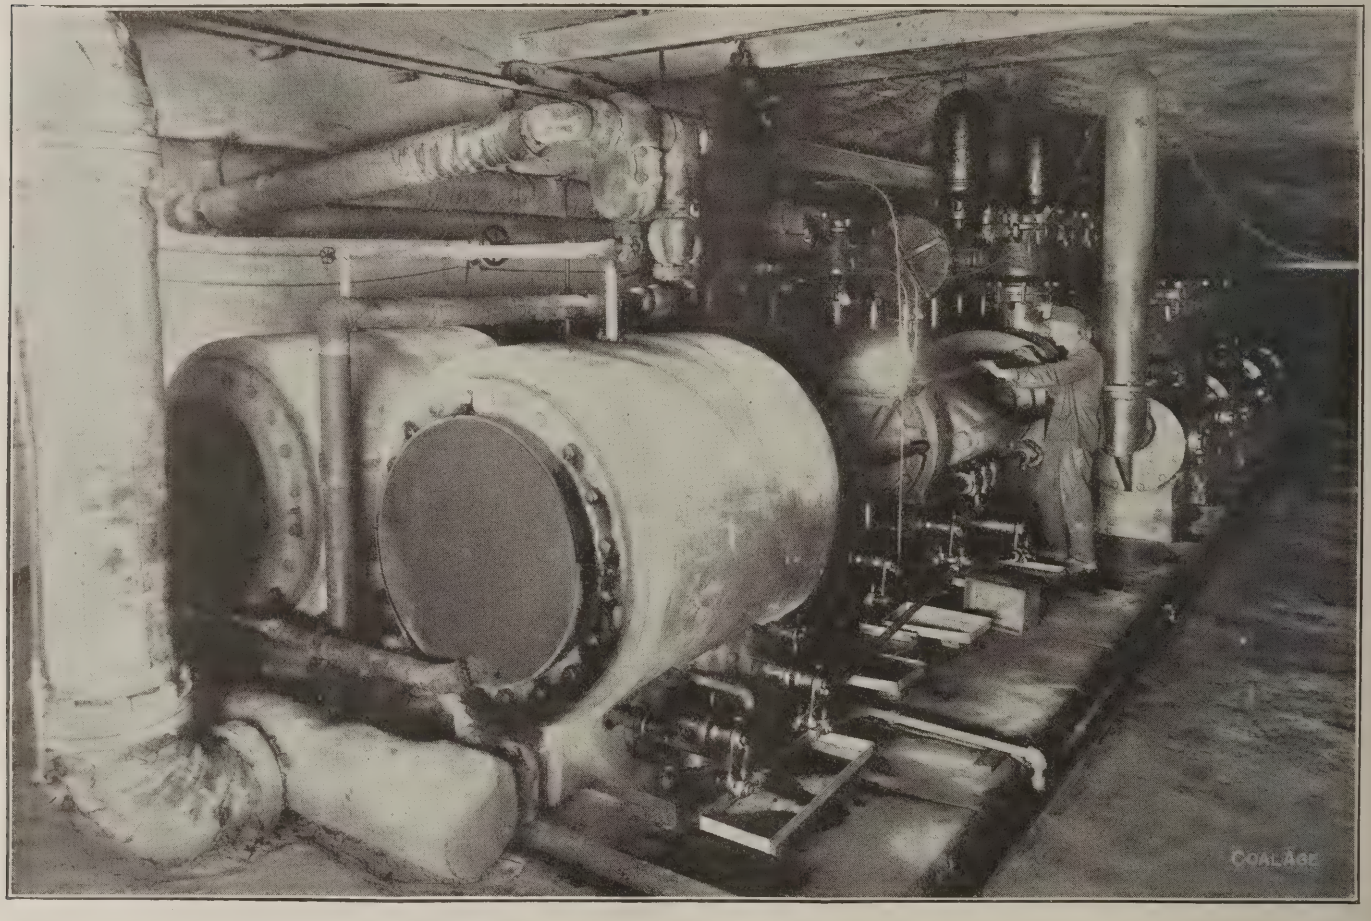
The repair of a broken, split or badly dented pipe may not be a serious problem provided the injured portion is accessible.

Recently a pipe under my supervision got a severe jam, cracked lengthwise and leaked badly. No amount of wrapping with cloth or tape proved effective, and it was evident that some other means would have to be taken to stop the leak.

Accordingly, I sawed the pipe in two at the break, and forced out the dent which had caused the metal to

Cross-Section of Pipe, Showing Method of Repair

split. I then slipped a short section of larger pipe over the break, carefully taped the sawed ends of the pipe together, placed the pipe section in a central position with regard to the break, puttied up the ends and poured lead into the space between the pipe and the covering section.



The method of procedure may be clearly seen in the accompanying drawing. The entire process did not require any great length of time and so far as leakage is concerned, there is no sign of a break. While a joint of this kind can be regarded only as an emergency repair, its strength and efficiency are nevertheless surprising.

Electricity may be transmitted through any substance, though in widely varying degrees. The conducting power of any material depends largely upon its physical state. For instance, the conductivity of air decreases rapidly as the pressure increases, while rarified air makes a fairly good conductor of electricity. The conductivity of all substances varies decidedly with change of temperature.

Two Reliable Mine Pumps

SYNOPSIS—Two compound pumps, each weighing 85 tons, that have been handling 3500 gal. of water per minute, 24 hr. per day, practically ever since their installation in July, 1908.

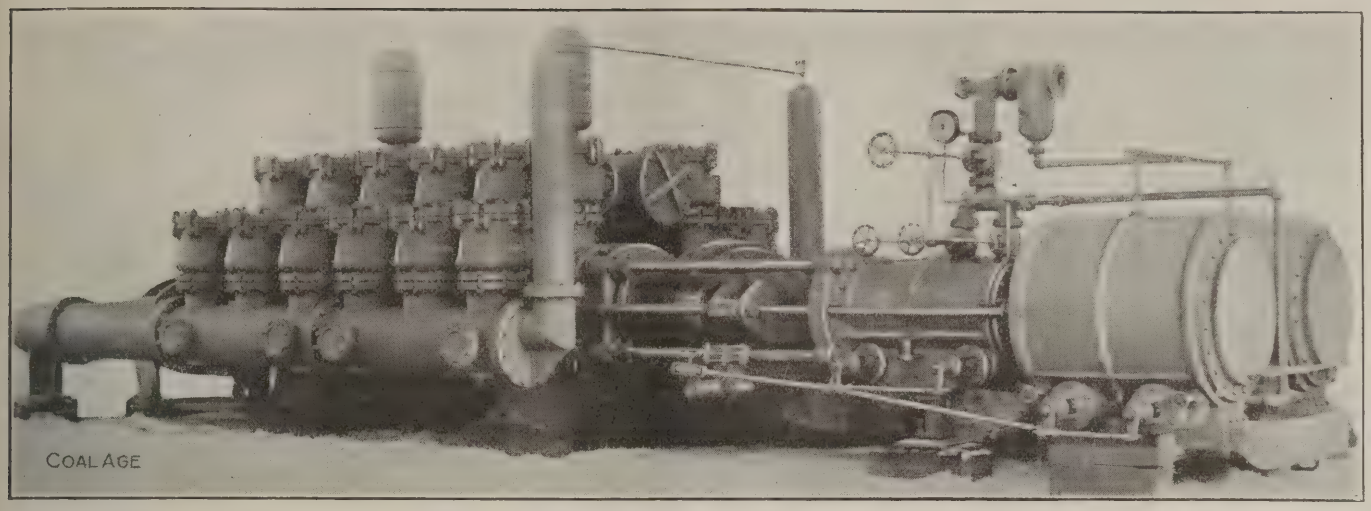
Few people not familiar with the business of coal mining realize the magnitude of the side issues that must sometimes be met. Dewatering a mine may be said to have no direct bearing upon coal digging, yet it frequently happens that unless the water is removed from an operation as rapidly as it enters, the production of coal ceases. In some instances the amount of water pumped or baled from the workings is many times the coal tonnage secured.

THE TWO PUMPS AS THEY APPEAR AT WORK UNDERGROUND

It will be recalled that the first successful steam engines ever built were mine pumps employing a walking beam and long vertical pump rods. While the English have tenaciously clung to a form of machine wherein the power-generating element is on the surface and the pump proper underground, the two being connected by vertical rods working in a shaft, Americans have developed a type wherein the steam and water elements or "ends" are in close proximity, the steam piston rods being rigidly connected to the pistons or plungers of the pump.

In the Jermyn mine of the Delaware & Hudson Coal Co., located at Jermyn, Lackawanna County, Penn., there are installed two compound duplex plunger pumps built by the Scranton Pump Co., of Scranton, Penn. Each of these machines is 41 ft. 3½ in. long over all, 13 ft. 1½ in. wide and 11 ft. 3 in. high to top of air chambers.

These pumps are placed end to end, in an underground pump house. The water ends are adjacent to each other, so that the two suction pipes lead direct to a single sump into which the mine water drains by gravity.



EACH PUMP WEIGHS 85 TONS

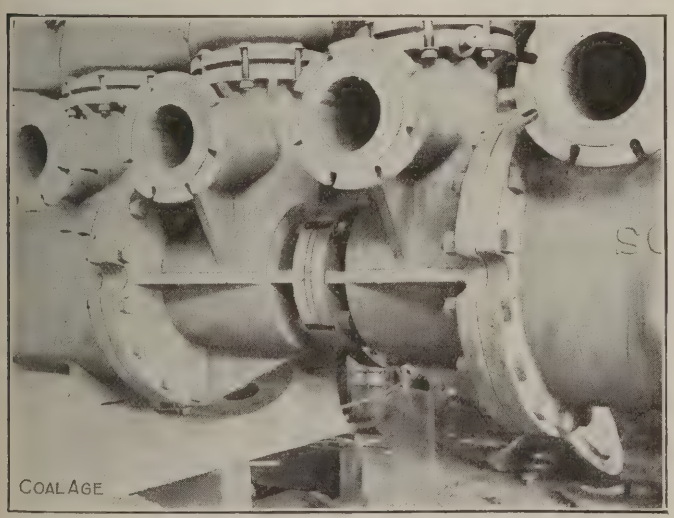
Each machine weighs approximately 85 tons and the capacity of each is 5000 gal. per min. The high- and low-pressure steam cylinders are 19 in. and 36 in. in diameter, respectively. The plungers are 21 in. in diameter and the stroke is 36 in. The suction pipe is 21 in. in diameter and the discharge is 18 in. The vertical head against which these pumps work is 300 ft.

Steam which is carried at the boilers at 120 lb. pressure is conveyed to the pumps through piping 350 ft. long. The steam admission opening of each pump is 5 in. in diameter, while the exhaust from the low-pressure cylinder is 10 in. in diameter.

Exhaust from each unit is made to a 12x18x18-in. single independent all-bronze jet condenser, about 6000 lb. of bronze being used in each of these machines, which were also built by the Scranton Pump Co.

Two semirotary steam valves are placed at the bottom of each steam cylinder. These strongly resemble the ordinary corliss valve, but of course are given a

ONE OF THE PUMPS ON THE ERECTING FLOOR



positive motion by the valve-rods. Furthermore, each valve serves both for admission and exhaust. The seats within which they work are bushings with milled ports. These seats are pressed in and doweled, but may be easily removed and renewed should necessity therefor arise. The low-pressure cylinder and both of its heads are jacketed with the drain from the eliminator.

The water end of each pump is provided with 24 bronze pot-valves working on gridiron bronze seats. These machines are believed to be the only ones now in use in the anthracite region supplied with this number of valves.

WATER-BARREL EXTENSIONS ARE EMPLOYED

These pumps embody an improvement upon ordinary pump design in the form of water-barrel extensions. Instead of lengthening out the water barrels to accommodate the 24-pot chambers and using an intermediate flange which acts as the wall partition, the barrels are made for the accommodation of only 16 pots and an elbow in the form of an extension is bolted to each barrel to which the remaining pots are secured. A small blind flange is fastened between each pair of elbows with four bolts and is doweled in place.

In making repairs or inspections, it is only necessary to knock out two dowel pins and remove four bolts, and the partition flange may be taken out. Removal of this flange allows the disengagement of the male and female connection between the barrel and the extension, and either extension or either barrel may be removed, together with the attached valve-pots or other parts, without interference with the balance of the pump.

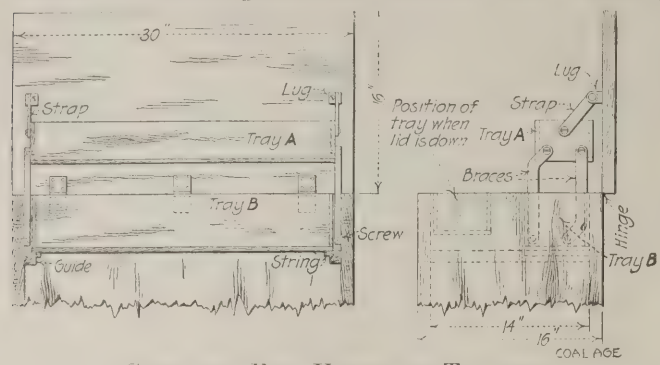
THE TWO WATER-BARREL EXTENSIONS AND PARTITION FLANGE

The entire water end, so far as possible, is wood lined. Where this is impracticable, bronze lining is employed. The steam and water ends are connected by four 3¾-in. steel rods upon each side. These are shouldered and provided with split collars to facilitate repairs.

As stated above, the capacity of each pump is 5000 gal. per min. Under ordinary circumstances, however, they are run at reduced speed and each handles about 3500 gal. per min. 24 hr. per day. They were installed in July, 1908, and have been in practically constant operation ever since, which speaks well for their design and general "dependability."

Mining Coal in China

The wages paid to coal miners in China are very small compared with those paid in European and American countries, being approximately as follows:



Foremen of mines, and coolies...	$10.00 to $17.50 per month
Mechanics	7.50 to 22.50 per month
Miners	12c. to 20c. per day
Coolies	6c. to 14c. per day

The low standard of skill counteracts much of the economy of the low wages in China, for the following reasons: (1) Greater amount of direction and supervision is necessary; (2) greater waste of material; (3) more ground has to be kept open for accommodating a larger number of men, which increases the cost of repairs; (4) more time taken in lowering and raising a larger number of men in and out of the mine; (5) want of ability to take care of themselves in an emergency, whereby the accident rate will naturally be high.

The cost of production at the pit's mouth in China, without considering interest and redemption of capital, is $1.25 to $1.50 per ton of coal. The miners are generally respectful and faithful to their superiors; they will work in narrow and badly ventilated, as also badly supported workings, and accept their lot cheerfully. They have a lack of thrift and thought for the future, and amuse themselves by attending theaters and gambling.

A Convenient Tool Box

A novel arrangement of tool-box trays has been introduced by C. C. Payton, of the Republic Iron & Steel Co., Sayreton, Ala. This consists in arranging one tray to rise and fall with the tool-box cover. The other tray is arranged to slide backward or forward in the ordinary manner. The arrangement and operation may be readily

SIDE AND END VIEWS OF TOOLBOX

understood by reference to the accompanying drawing.

The advantage of this tray arrangement is obvious, since upon raising the cover the contents of the entire tool box is immediately accessible.

Don'ts for Foremen and Assistants

Don't forget that your position and responsibility demand strict sobriety, and do not hire or allow to remain in your employ any subordinate official addicted to the use of liquor.

Don't forget that you have charge of all matters pertaining to ventilation.

Don't forget to post a notice at the fan engine house, stating the number of revolutions per minute the ventilator shall run.

Don't fail to have every working place examined at least once each day, and if practicable have a second examination made.

Don't fail to direct that the duty of the safety inspector is to look only after the safety of the employees during working hours, and that he is not to relieve the assistant foreman or fireboss of any of his duties.

Don't fail to have a report from each safety inspector every day, and if for any reason he is given other duties to perform, see that a competent person is put in his place.

Don't fail to read carefully the daily report of each assistant mine foreman, fireboss and safety inspector not later than the following day.

Don't fail on your daily inspection tours to see that General Rule No. 12 of the mine law is being complied with and that props are placed and fastened securely.

Don't fail to examine at least once a week all accessible parts of every abandoned portion of the mine in which explosive gases have been found, and immediately remove all dangers existing therein.

Don't fail to examine or see that daily examinations are made, in old sections of the mine being reopened, notwithstanding that these workings were formerly considered nongaseous.

Don't forget that thorough and efficient examinations and inspections before accidents bring better results than the same work after an accident.

Don't forget that we expect you to help us educate the employees to take care of themselves, and this can be best done by personal instruction and attention.

Don't wait for the general inspector to point out dangerous conditions.

Don't fail to take every precaution to insure the safety of the workmen in any portion of the mine that is dangerous or unsafe, and if necessary, withdraw all persons except those required to remove the danger.

Don't fail to see that every person is properly checked out of the mines, or accounted for, before you leave.

Don't allow a light other than a locked safety lamp to be used in any working approaching a place where there is likely to be an accumulation of explosive gases.

Note—Taken from Susquehanna Coal Co.'s book of instructions.

Don't allow anyone, except a duly authorized person, to have in his possession a key or any other contrivance for the purpose of unlocking any safety lamp in any place where locked safety lamps are used, nor to carry matches in said part of mine.

Don't fail to have an examination made before a blast is fired in a district where locked safety lamps are used.

Don't forget that whenever a place is likely to contain a dangerous accumulation of water, the workings approaching such place shall not exceed 12 ft. in width and that bore-holes shall be constantly kept in advance.

Don't fail to have an empty trip hoisted in any shaft or slope where the engine has been standing idle for one hour or more before men are hoisted or lowered.

Don't allow any person to ride upon any loaded car, cage or gunboat in any shaft slope or plane.

Don't allow more than 10 persons to be hoisted or lowered at any one time in any shaft or slope, unless more are allowed by the mine inspector.

Don't allow an accumulation of gas to be removed by brushing where it is practicable to remove it by brattice.

Don't fail to have investigated at once any dangerous conditions reported to you by the officials or workmen.

Don't fail to impress on the miners the importance of reporting any misfire, and after doing so, they shall go home for the day.

Don't fail to have safety holes made at the bottom of all slopes and planes and be kept free from obstructions.

Don't allow employees to travel on any slope or gravity plane while cars are being hoisted or lowered thereon.

Don't employ any person in a mine or section of a mine evolving explosive gases who is not competent to understand the rules and regulations.

Don't forget that not more than 75 persons shall be employed at the same time in any one current or split of air.

Don't fail to have all doors used in assisting or in any way affecting the ventilation hung and adjusted so that they will close automatically.

Don't fail to see that all main doors shall have an attendant, unless a self-acting door is used which is approved by the inspector of the district.

Don't fail to have all main doors so placed that when one door is open, another shall remain closed.

Don't fail to have an extra main door so placed and standing open, so as to be out of reach of accident, and so fixed that it can be at once closed in the event of an accident to the doors in use.

Don't fail to provide a substantial fastening for securing the door while being opened to pass the trips.

Don't fail to have the framework of all main doors substantially secured in stone or brick, laid in mortar or cement, having sufficient clearance between the car and frame on one side.

Don't fail to ascertain, once a week, the quantities of air in circulation, and enter same in the colliery report book.

Don't allow face of breast to advance more than 60 ft. beyond heading. Drive new heading.

Don't neglect to have a heading driven at the face of each breast when finished, to prevent an accumulation of gas.

Don't fail to enter in your report any danger observed in making your examination as required by law.

Don't fail to see that all dangerous or abandoned places in the mines are properly fenced off across the opening so that no persons can enter, and that danger signs are posted.

Don't fail to withdraw men immediately from affected portion of mine in case of accident to a fan.

Don't allow any miner or other person to carry matches where it is necessary to use locked safety lamps.

Don't fail to see that locked safety lamps are used when any others would be a menace to life and property.

Don't fail to see that all safety lamps are properly locked when used in gaseous districts.

Don't permit drill bits to be used unless at least one-eighth (⅛) of an inch larger than the diameter of the cartridge in use.

Don't fail to have doors and stoppings constructed as required by the mine law.

Don't forget that all gangways and main haulageroads driven hereafter where employees travel shall have a clear space of two and one-half (2½) feet from top of car to rib, and also to timbers, always on one side if conditions permit. Otherwise, provide ample safety holes on same side. Both to be always kept clear of obstructions.

Don't fail to keep the distance between prop and top rails of cars used in breasts at least three (3) feet, and space kept free of obstruction.

Don't allow platform, where used in gangways, to extend over top rail of car.

Don't allow chutes to extend more than twelve (12) inches over top rail of car unless they clear top rail at least sixteen (16) inches.

Don't neglect to remove or saw off all the chute or platform when a breast is finished or abandoned.

Don't forget to have examined, each working day, the shafts, slopes, travelingways, etc., as required by the mine law.

Don't fail to provide miners with a sufficient number of sawed up cap pieces of suitable size.

Don't fail to insist that the miner remain at work with his laborer, and do not allow the laborer to remain at work without the miner.

Don't fail to provide special cars in slopes for lowering and hoisting men.

Don't fail to direct and see that efficient safety blocks or devices are placed and maintained in good working order for preventing cars from running into shafts, slopes or planes where used by employees.

Don't fail to see that all hoisting ropes, safety catches, chains or bars, and all other hoisting apparatus are inspected, cones readjusted and bridle chains annealed.

Don't fail to observe the law relating to sinking new shafts.

Don't fail to have all permanent structures inside fireproof, including permanent air bridges.

Don't fail to correct any man you may see handling or using explosives in a faulty manner.

Don't fail to place danger signs when you find gas.

Don't keep a miner in your employ who opens a keg of powder with a pick, or who tamps his charge with an iron drill or needle.

Don't use, or allow to be used, open lights for testing brattice or stoppings for leakage.

Don't fail to notice any dangerous conditions when entering a working place, especially the "top."

Don't employ a man for work with which he is not familiar without giving him instructions, and also call his attention to the rules relating to his work.

Don't fail to keep mine telephones and signals in working order between the surface and all important parts of the mine.

Don't fail to instruct all persons in your employ to close all gates in shafts and slopes.

Don't fail to put up signboards indicating the direction of outlets to the surface.

Don't permit the storage of hay where the smoke may be carried into the main intake in case of fire.

Don't ride or permit others to ride on motors except for the purpose of making an examination.

Don't fail to observe the law governing the qualifications and duties of hoisting engineers.

Don't allow any person in a state of intoxication to enter any mine.

Don't fail to report all accidents as quickly as possible.

Don't fail to have an efficient alarm attached to the front end of every trip pushed by a motor.

Alabama Rate Increase

Following in the wake of the 5 per cent. increase in freight rates granted the Eastern lines, the Southern railroads, operating out of the Birmingham district, have petitioned the Alabama Railroad Commission and the Interstate Commerce Commission to be allowed to increase their freight rates on coal to practically all points in Mississippi, and some in Alabama, Tennessee and Louisiana, 10 to 33 per cent.

From the standpoint of both the Alabama operator and the consumer, this is one of the most important matters ever presented to these bodies; to the operator because it will undoubtedly reduce his territory, which has gradually grown smaller year by year, due to excessive freight rates from this district and more advantageous rates from other districts; and to the consumer because, should he be situated where he cannot get coal from another district, he must stand the additional freight.

It is a well known fact that Alabama in recent years has lost practically the entire state of Georgia, due to the low rates from Tennessee, Virginia and West Virginia, and now the railroads, instead of coming to the assistance of the operators, are asking that they be allowed increases in their rates that will still further curtail the Alabama production. What is true of the territory east of Birmingham, just mentioned, also applies to that north and west. Northern Alabama, on the edge of the Alabama coal fields, gets most of her coal from Tennessee, due to the already too high freight rates from the Birmingham district. Mississippi, just west of these fields, gets most of her fuel from Illinois and Kentucky, for, notwithstanding the fact that the distance is at least 50 to 75 per cent. greater from Kentucky and Illinois fields, the freight rates to practically all Mississippi points are the same from Illinois and Kentucky as from Alabama. And yet the railroads request that they be allowed to raise their Alabama rates.

There are contracts now with Alabama operators amounting to hundreds of thousands of tons of coal from the railroads traversing the Atlantic seaboard, and should the freights be raised, these contracts would be placed in Tennessee or West Virginia. This also applies to the lines in the Mississippi Valley, as they will probably draw their fuel supply from the Illinois and Kentucky mines.

While the proposed rates cover practically all points, a few of the most important are as follows:

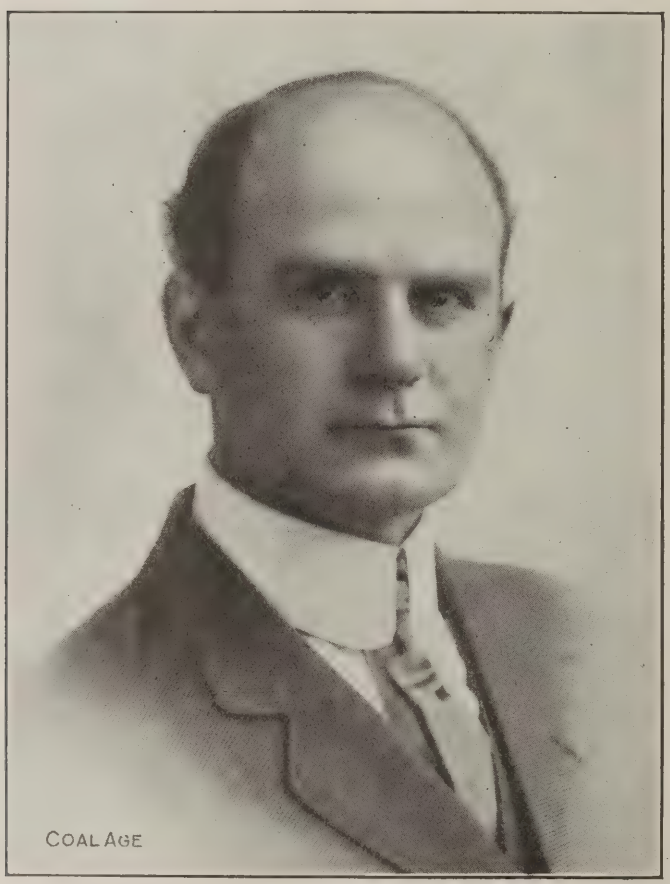
To:	Present	Proposed	To;	Present	Proposed
Birmingham, Ala....	$0.30	$0.40	Memphis, Tenn.....	$1.10	$1.25
Birmingham, Ala....	0.40	0.50	Columbus, Miss.....	0.95	1.10
Anniston, Ala.....	0.50	0.70	Gulfport, Ala.....	1.25	1.40
Gadsden, Ala.....	0.50	0.70	Jackson, Ala.....	1.45	1.60
Alabama City, Ala...	0.50	0.70	Meridian, Ala.....	1.10	1.25
Sylacauga, Ala.....	0.50	0.70	Natchez, Ala.....	1.55	1.70
Attalla, Ala.....	0.50	0.70	Vicksburg, Ala.....	1.45	1.60
Talladega, Ala.....	0.30	0.70	West Point, Ala.....	0.95	1.10
New Orleans, La.....	1.25	1.40			

The Chamber of Commerce of Birmingham has taken the matter up, as well as the Alabama Coal Operators Association, and is preparing to make a strong fight at the hearing before the Alabama Railroad Commission, on Sept. 16.

It is estimated that should these increases be allowed, the Alabama production will be curtailed 10 to 15 per cent. annually.

Hungarian Coal Industry in 1913—Despite the unfavorable condition of industries in general, 1913 was a good year for the coal-mining industry, owing in part to the greater demand for coal by the Royal Hungarian state railways. There was a slight increase in the imports of hard coal, briquettes and coke and a decrease in the imports of brown coal. The total imports of brown coal, coke, hard coal and briquettes amounted in 1913 to more than 5,200,000 tons, against 4,870,000 tons in 1912. Exports of these articles in 1913 amounted to slightly more than 390,000 tons, a decrease of about 40,000 tons from 1912. The production of Hungarian coal mines in 1913 is estimated at 10,568,000 tons. Hungarian coal deposits are estimated to contain over 350,000,000 tons in sight, plus available resources of 1,358,000,000 tons.

The coal mines owned and operated by the Hungarian Government have not been profitable. The balance sheet of the Vodnik coal mine showed a net loss of $82,215 at the end of 1911 and of $129,920 at the end of 1912. The books of the Komlo coal mine, likewise operated by the Hungarian Government, showed at the end of 1911 a net loss of $25,578, and at the end of 1912 a net loss of slightly more than double that amount. Other mines owned and operated by the government have also been operated at a loss. It is estimated that the net loss to the government on all the coal mines it owns and operates will be at least $300,000 in 1914.



Pure copper possesses many physical properties of great engineering value in addition to its high electric conductivity. It has, to a marked degree, the qualities of malleability and ductility, which make it an ideal metal for wire drawing. Its strength and hardness are greater than that of any other base metal, except iron. It has the power of resisting oxidation, takes a high polish, is easily worked, and can be forged easier than iron.

Who's Who in Coal Mining

George Watkins Evans

Coal mining in the Northwest is becoming quite an industry, and in keeping with the progress of the business itself, a number of engineers are advancing to positions of prominence in the great industrial life of our Pacific Coast country. One man who has rendered valuable services to the fuel industries of Washington and neighboring states is George Watkins Evans, consulting mining engineer of Seattle.

Mr. Evans was born at Abercarn, South Wales, in 1876. He comes of a line of coal-mining men, all of

GEORGE WATKINS EVANS

whom have been connected with the coal industry of Wales since its beginning. His education was obtained in the Washington State College, where he graduated from the mining school with a B. S. degree in the class of 1903.

His experience in the mines dates back to a period previous to his university work, and covers more than 12 years of service in various positions. He also spent five years in Geological Survey work, and for three years was geologist in charge of coal surveys for the Washington Geological Survey.

Following his work for the State of Washington, Mr. Evans did consulting mining work for the U. S. Navy, making a report on the "Alaska Coal Situation." Finishing his work in Alaska, he spent some time as examining engineer for Canadian capitalists, and at the present time is serving as consulting mining engineer, coal division, of the Northern Pacific R.R. He is also consulting mining geologist of the Carbon Hill Coal Co. and mining engineer of the Hyde Coal Co.

Mr. Evans has done a considerable amount of technical and engineering writing. One of his most important works is "The Coal Fields of King County." His report on the Ground Hog anthracite coal field of British Columbia, and his Report to the U. S. Navy on the Matanuska coal field, are authoritative documents and have been read with interest by all coal men interested in the fields covered.

Mr. Evans is an active member of the American Institute of Mining Engineers and was recently appointed by the Institute to serve on the newly created "Coal and Coke Committee." Few men are better acquainted with conditions in the Western coal fields of this country and Canada than Mr. Evans, and there is no doubt but that the character of his work entitles him to rank as one of the principal coal authorities of the Pacific Coast.

The Contraband Question on the Great Lakes

On the matter of coal shipping on the Great Lakes, the United States government has issued the following instructions to collectors of customs:

1. You will permit foreign-bound vessels in your district to clear only after they have filed with you their full and final manifests.

2. You will notify all merchant vessels in your district that they will be subject to inspection and examination of documents, ships, and cargoes by United States authorities before clearance is given, and will be subject to further examinations after clearance, and while such vessel remains within the territorial waters of the United States. Such vessels shall stop and lie to for examination when signaled by a United States vessel.

3. Any foreign-bound vessel whose character as a merchant vessel is established to your satsifaction is entitled to clearance (under the above conditions), no matter what the character of her cargo, or what her destination.

4. You will not refuse clearance to merchant vessels, whether of the United States or other neutral power, or whether of a belligerent power, solely on the grounds that the vessel contains contraband of war.

Coal Mining in South America

None of the South American countries rank as important coal producers. Chile mines about 1,000,000 tons of coal annually for steamship purposes at Lebu and Tolcahuano. Peru mines 330,000 tons annually, while Brazil, Argentine, Venezuela and Colombia produce no coal of consequence.

In Peru, the coal industry is controlled by an American (U. S.) concern, the Cerro de Pasco Mining Co. Their fields are at Goyllarisginsga and Quis-Knarcancha.

Colombia has most extensive beds of coal adjacent to the Panama Canal. These fields would seem to have a bright future, and are worthy the attention of American capital. Practically all the lowlands on the entire north coast of Colombia are underlaid with a good grade of fuel.

The practical unit of electrical resistance is the international ohm, which is the resistance offered to an unvarying electric rurrent by a column of pure mercury at a temperature of melting ice, 14.4521 grams in weight (0.51 oz.) of a constant cross-sectional area, and 106.3 cm. (41.85 in. in length). To obtain a concrete idea of this unit, it should be remembered that a copper wire, having a diameter of $\frac{1}{10}$ in. has, at 68 deg. F., a resistance of approximately 1 ohm per 1000 ft.

Editorials

When the present war commenced, great alarm was felt by American coal operators over the possibility of an exodus of alien miners to Europe to serve in the armies of their native countries. Much of this fear was unfounded as subsequent events have proved. Here and there, we find instances where a dearth of labor has handicapped operations, but generally the expected outflow has not materialized to such an extent that vacancies in the ranks of labor could not be filled. In fact, taking the country as a whole, and considering all its varied industries, careful estimates show that of the 40,000,000 workers in the United States, less than 800,000 have citizenship in the nations at war.

However, where the European war does cause a scarcity of labor in this country through aliens returning to fight, the industry affected will necessarily be obliged to turn more earnestly to the use of machinery, and there could be no more happy solution for the problem. A demand for more mechanical appliances means greater prosperity for our factories and mills that supply such equipment. The history of every recent war shows that inventive genius has supplied the machinery needed to do the work of absent men.

So far as precedent is concerned, there is no basis for the belief that the European war will prostrate business throughout the world for long. During the American civil war, this country entered a period of record production in many of our factories and mills. It is also interesting to note the effect of the Napoleonic wars on the trade of the United States. All Europe was fighting while America was at peace. During the 15 years covered by the European struggle, American foreign trade increased nearly 500 per cent., and the tonnage of American ships even more.

Mine Fires

During the past year there have been a number of serious fires on the surface and underground at various coal mines. These disasters should teach all coal men the advisability of adopting measures to prevent such accidents. A mine fire always has dire possibilities, because of the great number of men who are likely to be affected.

Practically all mine managers realize the dangers that may result from the use of timber in the construction of headgears at colliery plants. It cannot be long before the laws of all coal-producing states will rule against the use of wood in structures adjacent to mine shafts.

We are also coming to recognize the necessity of having a trained fire brigade of colliery employees at every mine. Such a corps of experienced men could render prompt service in overcoming any fires that might occur. This is an age of specialization and men who are quite familiar with improved methods of rescue work are frequently ignorant concerning the best practice in extinguishing a serious mine fire.

One lesson taught by recent fires is the great importance of being able to reverse the mine ventilation. Not so very long ago a fire occurred in the workings of a European mine. At a critical moment the fan stopped, and it appeared impossible to save the lives of the men underground. Fortunately, the downcast shaft contained a number of steam pipes, and the presence of these caused the air to automatically reverse—the downcast shaft becoming an upcast. Many other instances might be cited where the reversal of ventilating currents saved the lives of men.

If you haven't a trained fire brigade at your colliery, organize one immediately and arrange for a course of instruction for the men which will cover the very latest practice and include all modern ideas with reference to the successful handling of mine fires.

The Union's Attitude to Safety

The miners' unions are favorable to safety and first-aid. It is true that occasionally the miners, as at the Delaware, Lackawanna & Western R.R. Coal Department mines, object to the patrolmen but much of that feeling is due not so much to a lack of interest in safety as to an objection to the personnel of the patrol corps or because of a dislike of close supervision. The persons selected for the inspectional patrol are middle-aged and active men of training who are suited for advancement in official capacities and the older miners irk at the authority given them by the company.

Most of our managers would not like to have men at their elbow always nagging them about safety. A little irritation should not be unexpected, at least until the men get accustomed to the unwonted interference. The operator, if we rightly recall, has been known at times to find that important functionary, the state mine inspector, an annoyance and as to some operators' opinions of certain clauses of the mine law, the less said the better.

Indeed, perhaps the operator is sometimes right and the law wrong and even at the face, the miner of many summers may be sometimes correct in his judgment and middle-aged patrolmen wrong. Still laws are good and so are mine inspectors and we believe patrolmen will also serve a good end. Meanwhile let us keep our perfect balance, for the man behind the desk and the man at the face on the whole are at one in wanting to see a safe mine, and perhaps if there is any difference between them, the latter is the man most interested for if the roof falls it is his head or his back which is broken.

We know the old rhyme about "all the bigger fleas have little fleas to bite 'em and little fleas have littler fleas and so *ad infinitum*." The miner must not think he alone is hectored. When the operator is told that he must put in a larger fan, he is as much heckled as the man who is sent out to get his auger made to gage and some operators act in the same petulant manner as the men they employ and say they will shut down rather than comply.

So the operator must "sit tight" on this subject. The probabilities are that he has in his mine, a lot of sympathizers with his safety notions. It is interesting to note that at Charleroi, Penn., when subdistrict No. 3 of district No. 5 of the United Mine Workers of America held an annual outing of miners, the main features were first-aid speeches and field practice.

The unions are giving prizes for first aid and several of them have indorsed the movement and a certain enthusiasm is spreading fast; only there is, of course, a natural feeling against it because the operator will persist in publishing that the miner is to blame for most of the accidents. Of course he is. What else could be expected? There are 200 or 300 men in a mine. If the operator is to blame as often as his men, he is taking more than his due share in making the mine unsafe.

Though the miner is frequently to blame he is probably filled with a due sense of responsibility, but he does not like to be always reminded that the operator thought of safety before he did. After all, it is doubtful if the operator has a patent or even a copyright on "Safety first." This only is probably true: That when the idea did light on him, he had the time and the money to make his wish a general practice.

Let us wait and we shall see that the unions and the individual men will do their part. Sometimes we are apt to think that all they care for is to puzzle out expensive legislation for the operator. But there is another kind of activity and who will say they do not exhibit it?

Ventilation Rules

A study of the laws of the various countries regulating mine ventilation is an enlightening occupation. In no country have the authorities covered the subject in a more comprehensive manner than in France. The French laws aim at three things, (a) a supply of air sufficient to insure hygienic conditions, (b) enough air to avoid an excessive rise of temperature, and (c) sufficient ventilation to guarantee the absence of danger arising from foul gases or smoke.

In French mines the speed of the air current in the shafts and entries must not exceed 26 ft. per sec., except in such places as are not ordinarily used for the transport of material or the traveling of persons. The law only requires that each man be supplied with 1.77 cu.ft. of air per sec., and inspectors satisfy themselves as to the mine owners compliance with this latter requirement by measuring the quantity of air at the intake, and then dividing that quantity by the number of men underground. They further endeavor to see that the bulk of the air reaches the faces of the workings.

The French idea of dividing all mines into three classes; namely, distinctly fiery, slightly fiery and non-gaseous, is a good one. The decision as to which class a mine belongs is left to the local inspector in conjunction with the mine owner and a representative of the workmen. This classification of a mine may relate to the workings as a whole or only to an independent section. The classification of mines in respect to coal dust is on lines similar to that on firedamp.

Another interesting rule of the law is that which fixes a maximum temperature in which men may work underground. This prescribed temperature is 95 deg. F. on dry bulb, or 86 deg. F. on wet bulb.

There is much that legislators who busy themselves in writing laws to control operations in American coal mines might learn from a perusal of mining regulations of some of the European countries. What we need in America is not so much quantity in mine laws as quality. It is inadvisable to enact measures that cannot be enforced at all, or to pass laws that greatly burden operators, without resulting in the attainment of any desirable end.

Animal versus Mechanical Haulage in Mines

Several humane societies, especially in Europe, have as their real object the removal of horses, mules and ponies from mines. We are pleased to note, however, that their original views and aims are somewhat modified. Investigation showed that the evils attendant upon the use of animal haulage in coal mines cannot be abolished at one fell stroke.

The investigators had little trouble in proving that mechanical haulage, as a general rule, is cheaper, faster and more sanitary. It was further shown that where conditions such as suitable gradients, continuity of seam and absence of faults are found, it would be possible for mechanical haulage to entirely supersede horses in new mines, and also in the extension of some old mines where there is a source of power available at a convenient point.

On the other hand, it was evident to those conducting the research that at certain old collieries it might be possible to adapt the workings for mechanical haulage, but at a prohibitive cost. It is interesting to note the conclusions arrived at by the National Equine Defense League officials in England, which organization recently collected data covering the subject of animal haulage in coal mines. Following their research this policy was announced:

(1) To secure by legislation the best possible conditions for the horses and ponies that must be employed in mines.

(2) To insure that no more horses than are absolutely necessary shall be used in mines at the present and for the future.

(3) To promote the use of mechanical traction wherever possible.

Prevention of Breakage

In many places, the question of breakage in loading and handling coal is an important problem. A considerable number of mechanical appliances have been installed to meet the needs of each case. No one solution is of greater value than the belt conveyor. At one mine where rapid dispatch and careful handling were essential, the owners supplied themselves with a coal-belt elevator capable of dealing with 700 tons of coal per hour.

This particular conveyor was 207 ft. long and 42 in. wide; it was carried on a fixed steel girder, and delivered the coal by means of a telescopic shoot provided at its outer extremity with a revolving lip. The entire belt was driven by electrical power.

Under certain conditions, there is nothing that equals the belt conveyor as a means of handling large outputs of coal when the product is easily liable to fracture.

Legal Department

Power of Legislature to Regulate Coal Mining

By A. L. H. Street*

In sustaining the validity of the law enacted in Ohio, Feb. 5, 1914, which regulates the weighing of coal at mines where miners are paid according to quantities produced, and which empowers the Industrial Commission to fix the standard for compensation in case of dispute between operators and miners, the United States District Court for the Northern District of Ohio said in the recent case of Rail & River Coal Co. vs. Yaple, 214 Federal Reporter 273:

"Without determining the soundness of the argument that the act, indirectly at least, establishes a minimum wage, in that it insures the miner full pay for all coal mined in accordance with the prescribed regulation, it may not be said that, in supplying an incentive for more effectually securing the removal of fine coal and coal dust to the surface, and thereby minimizing or dissipating the danger arising from their continued presence in the mines, the act does not provide for the health, safety and general welfare of employees. Furthermore, section 36 was designed to limit, by appropriate legislation, the freedom of contract as regards the methods of mining, weighing and measuring coal. We are not prepared to hold that the Legislature, acting within the scope of that section, may not say that the business of mining coal is so far affected with a public interest as to justify appropriate regulation of the manner of paying employees when they are to be paid according to the quantity produced, and when such regulatory statue will operate to allay discord and strife and conserve the coal supply. The Ohio act does not restrict the right of contracting for the labor of miners by the day, week, month, or year, or in any other manner (except as to quantity) that the operator may deem proper. If the miner or loader by the terms of his employment is to be paid by the ton or weight, the right of contract is then curtailed to the extent that he shall be paid according to the total weight of the coal contained in the mine car, such contents to include, however, no greater percentage of slate, sulphur, rock, dirt, or other impurities than is unavoidable, as determined by the Industrial Commission. If the employee should send to the surface an excess of such impurities, or any of them, the operator is not required to accept the car or pay for its contents as delivered, but is at liberty to agree with him as to the deductions to be made on account of impurities. If no agreement is made, the offending employee may be prosecuted for his violation of the Commission's order as for a misdemeanor. If he be unable or unwilling to pay the fine imposed, he may be imprisoned in the county jail until his fine and costs are paid, or secured to be paid, or he is otherwise legally discharged, provided he be given credit upon his fine and costs at the rate of 60c. per day for each day's imprisonment. He is thus subjected to penalties which are neither obscure nor uncertain. The act does not require the operator to mingle the contents of such a car with the other coal produced, or prevent his removing, by screening or otherwise, the excess of any impurities. It must be presumed that the Industrial Commission will perform its official duty and fix a standard which will exclude all slate, sulphur, rock, dirt, or other impurities, except such as is unavoidable. The operator, if given the unrestricted right of contract, could do no more. If dissatisfied with the Commission's order, which by statute is made *prima facie* reasonable and lawful, he may petition for and obtain a hearing before the Commission as to those features, and may thereafter have a speedy review of its action by the Supreme Court of the state. * * * The law permits the employer and employee to stipulate as between themselves what percentage of coal commonly known as nut, pea, dust and slack shall be allowed in the output of the employer's mine. It is only in case of their disagreement that the Commission may designate such percentage, and its orders in that behalf must possess the same characteristics as those above mentioned, and are likewise subject to rehearing and review."

*Attorney-at-law, St. Paul, Minn.

Recent Legal Decisions

When Contract to Sell Coal Property Will Not Be Enforced—Suit cannot be maintained to compel performance of a contract to sell coal underlying land, when it appears that the purchaser took the contract for speculative purposes and was unable to perform his part of the agreement until he found a purchaser, and where he delayed four years in demanding a deed. (West Virginia Supreme Court of Appeals, Wilkinson vs. Poling, 82 Southeastern Reporter, 47.)

Oklahoma Gross Revenue Tax—In a decision recently handed down by the Oklahoma Supreme Court, in the case of McAlester-Edwards Coal Co. vs. Trapp, 141 Pacific Reporter, 794, the validity of the following tax law of that state is sustained: "Every person, firm, association or corporation engaged in the mining or production, within this state, of coal . . . shall within 30 days after the expiration of each quarter annual period expiring respectively on the first day of July, October, January and April of each year, file with the state auditor a statement under oath, on forms prescribed by him, showing the location of each mine . . . operated by such person, firm, association or corporation during the last preceding quarter annual period, the kind of mineral . . . the gross amount thereof produced; the actual cash value thereof, and such other information pertaining thereto as the state auditor may require, and shall, at the same time, pay to the state treasurer a gross revenue tax, which shall be in addition to the taxes levied and collected upon an ad valorem basis upon such mining . . . property and the appurtenances thereunto belonging, equal to 2 per centum of the gross receipts from the total production of coal therefrom." Plaintiff mining company is operating under leases from the Federal Government made for the benefit of the Choctaw and Chickasaw tribes of Indians, and unsuccessfully sought to have the law declared invalid as to it on the following grounds: That it does not specify the purpose for which the tax was levied. That it violates the federal constitution in that the United States Government has sole control over the land where the coal is mined, and has granted the company the right to mine such coal, and that the law constitutes an attempt to tax its rights under its leases.

The Lehigh & Wilkes-Barre Co.'s Meet

First-aid teams from the four districts of the Lehigh & Wilkes-Barre Co. competed at Sans Souci Park, near Wilkes-Barre, on Monday, Aug. 31, that being the company's fifth annual field day.

A general holiday was declared for all men engaged in first-aid work, and about 800 men and boys were gathered on the field when the opening event started. Each year there has been increasing interest in these contests, but this year's competition eclipsed that of former years, and while the rivalry was along spirited lines, a friendliness was manifested among all competing teams which indicated that the men in general are striving for proficiency and that they put service to fellowman above all else.

The teams in each of the four districts competed with each other in four different events. The boys, moreover, had an event of their own. Then the winning teams of each district contested for supremacy with each other. The Parrish inside team carried off the chief prize, each member of the team receiving a bronze medal. In the preliminary event this team made the splendid average of 99, and the work in the final event was so well done that the judges awarded them a rating of 98. The boys' event was won by the team from the Wanamie colliery, with a rating of 96. This team carried off that event last year.

THE LEHIGH & WILKES-BARRE CO.'S LITTER SQUAD

Dr. G. W. Geist, of Wilkes-Barre, was in charge of the program. He is at the head of the company's first-aid work. Edward Griffith, secretary to President Charles Huber, of the L. & W. company, rendered efficient service in working out the details. The judges were Dr. D. H. Lake, in charge of the first-aid work of the D., L. & W. R.R. Coal Department, and Dr. J. H. Hughes, of Nanticoke, Penn. After the events were over the remainder of the day was spent socially.

Event No. 1—This event was for all first-aid teams of the outside and inside corps of the Wilkes-Barre district. The problem given was as follows: "Treat a simple fracture of middle right thigh, a burn of left hand, wrist and forearm and an injury to right eye. Treat for shock, dress fracture with long and short splints and triangulars; dress for burn. Use gauze, cotton or waxed paper and circular roller; dress the eye. Use compress and 2-in. roller."

The judges made the following rating on this event:

Hollenback colliery—Outside corps, 95½; Inside corps, 93½; South Wilkes-Barre colliery—Outside corps, 93½; No. 3 shaft corps, 93; No. 5 shaft corps, 91½; Stanton colliery—Outside corps, 98; Inside corps, 89; No. 4 slope corps, 94; No. 4 shaft corps, 93; The Stanton Outside corps was declared the winner of this event.

Event No. 2—The second event was for all teams, inside and outside, of the Plymouth district, and the problem given was as follows: "Treat a simple fracture of middle of right leg, simple fractures of both forearms and a cut over right temple. Treat for shock. The dressing for the leg should be short splints extending from middle of thigh to 1 in. or more below the foot using triangular bandages; dress cut, using compress and Gibson roller; dress forearms, using anterior and posterior splints and roller bandages."

The judges awarded the following points: Lance colliery—Outside corps, 94½; Inside corps, 98; Nottingham colliery—Outside corps, 93½; Inside corps, 90½; No. 16 Inside corps, 9?½; Buttonwood colliery—Outside corps, 98; Inside corps, 88; Parrish colliery—Outside corps, 87½; Inside corps, 99; the Parrish Inside corps was declared winner of this event.

Event No. 3—All outside and inside corps of the Ashley district competed in the third event. The problem follows: "Treat a compound fracture, 2 in. below middle of left thigh. Much hemorrhage of bright-red blood supervenes; victim has a punctured wound of the chest between third and fourth ribs on the right side, and a laceration of the left temple. Treat for shock; dress for fracture with long external and short internal splints and triangular bandages, using tourniquet to stop bleeding. Dress wound with compress and 2-in. circular roller bandages from chest to waist with suspender over the right shoulder; dress for cut with a cravat bandage with middle of bandage and knot over wound and the turn on opposite side.

Points scored by the various teams in this event follow: Sugar Notch colliery—Outside corps, 85; Inside corps, 95; Wanamie colliery—Outside corps, 96½; No. 2 slope corps, 89½; No. 3 slope corps, 93; Maxwell colliery—Outside corps, $92; Baltimore shaft corps, 94; Red Ash shaft corps, 94.

Event No. 4—This event was for all outside and inside corps of the Honey Brook Division and the problem was as follows: "Treat a simple fracture, 1 in. above the middle of left thigh; fracture of jaw bone and lacerations of middle

Scranton Outside Corps
Winners of Event No. 1

Audenreid Outside Corps
Winners of Event No. 4

Wanamie Outside Corps
Winners of Event No. 3

finger of right hand and thumb of left hand. Treat for shock, using dress compress over wounds; stiffen fractured thigh with long external and short internal splints and secure with triangulars; dress finger and thumb with Spica bandages and the jaw with a Barton roller. The points allowed by the judges were: Honey Brook colliery—Outside corps, 94½; No. 15 slope corps, 97; No. 20 slope corps, 93; Audenried colliery—Outside corps, 98; Inside corps, 97.

Event No. 5—All breaker-boys corps competed in this event and the contest created much interest, not only for the boys, but for the adults also. The problem in this event follows: "Bandage fingers, hands, wrist, elbow, arm and shoulder with 2-in. rollers, using spiral reverse and spica as best adapted to different portions of limbs; also make a Barton bandage of the head."

Points allowed by the judges follow: Hollenback colliery, 94½; South Wilkes-Barre colliery, 92½; Stanton colliery, 93; Sugar Notch colliery, 95; Lance colliery, 93; Nottingham colliery, 93½; Wanamie colliery, 96; Maxwell colliery, 88.

Event No. 6—The Litter Squad of the Lehigh & Wilkes-Barre Co. gave an exhibition drill as the seventh event. For 15 minutes the members of the team held the strict attention of the crowd as it executed various moves and showed its thorough training in litter work.

Event No. 7—This was the big event of the day. The winning teams in the first four events were competitors in the final. The problem was as follows: "Bandage foot, ankle, leg, knee, thigh and hip with 2½-in. rollers, using spiral reverse and spica as best adapted to different positions of the limb; and also make a Gibson bandage of the head."

Points were scored as follows: Stanton colliery—Outside corps, 93; Wanamie colliery—Outside corps, 93; Parrish colliery—Inside corps, 98; Audenreid colliery—Outside corps, 94.

When the last event was over the 800 employees and friends of the Lehigh & Wilkes-Barre Coal Co. went to the upper pavilion of the park and a dinner was served. An orchestra and a glee club from Plymouth rendered several selections. Many of the favorite songs of the day were sung by the guests and Attorney A. H. McClintock, of Wilkes-Barre, was introduced as the speaker of the day. He had just returned from Europe, having had much difficulty in leaving the Continent. He was arrested as a German spy, and many of the stirring events that had taken place on the Continent were fresh in his mind.

Attorney McClintock then presented pennants to the captains of the Stanton Outside, the Parrish Inside, the Wanamie Outside, and the Audenreid Outside teams as a sign of leadership in the events in which they had competed. Then the members of the Parrish Inside team were presented with bronze medals. The captain of the Wanamie Boys' team also received a pennant.

Boys' Corps at Wanamie Colliery
Winners of the Boys' Event

Mining Education in Anthracite Region

The fourth annual report of the Nanticoke district Mining Institute shows a membership of 821 as against 679 last season. There were six meetings of the Nanticoke mining classes with an average attendance of 432. Last season this average was 199. The enrollment of the classes increased from 657 to 841. At the state examinations for mine foreman's and assistant mine foreman's certificate 6 members passed the examinations for the former and 24 passed those for the latter

The fourth annual report for the Shamokin-Mt. Carmel District Institute shows a membership of 788 as against 571 last season. There were seven meetings of the mining classes with an average attendance of 313. Last season this average was 127. The enrollment of the classes increased from 763 to 1016. At the state examinations for mine foreman's and assistant mine foreman's certificates 2 members secured the former and 32 secured the latter.

The first annual report of the new Williams Valley District Institute shows a membership of 332 and ten meetings with an average attendance of 244. The fourth annual report of the Lehigh Valley Coal Co.'s mine schools at Centralia and Lost Creek shows that the enrollment increased from 51 to 65. Two students secured mine foreman's certificates and 9 obtained certificates as assistant mine foremen during the present year.

The Lehigh Valley Coal Co.'s mine schools are not under public-school board control, yet they are open to all, and 13 of the students this year were not in the employ of that company. In addition the company maintains at Drifton an apprentice school where attendance is compulsory, but the students are paid at their regular rate for the time engaged. This school has completed its sixth successful year.

The Philadelphia & Reading Coal & Iron Co. also privately maintains schools for its miners at Mahanoy City, Shenandoah, Minersville and Pottsville, and many of the students from these passed the state examinations for the coveted mine foreman's and assistant mine foreman's certificates. The state reimburses two-thirds of the annual expenses of those schools under public-school control.

Garden Awards in Colorado

By Fred W. Whiteside*

The second annual contest for the Victor-American Fuel Co.'s lawn and garden prizes was held early in this month. Three prizes of $25, $15 and $10, respectively, are offered annually in each town where a contest is held.

The only conditions imposed are that there be three or more contestants, and that those competing for the awards be *bonafide* residents of the town in which the Victor-American Fuel Co.'s mine is located.

The superintendent, doctor and mine clerk are excluded from receiving awards in the contest; although the judges are pleased to give anyone of them honorable mention, should he deserve it. A noticeable improvement was observed this year over that of last, when the first contest was held, many more participating, and of those who entered in 1913, a marked advance was attained in nearly all cases.

*Chief engineer, Victor-American Fuel Co., 307 Ernest & Cranmer Bldg., Denver, Colo.

First Prize Winner at Chandler, Colo.
(Gus Hutter)

In order to make the contest general, no distinction was made between lawns, flower or vegetable gardens. If the plot contained but cabbages, turnips and onions, it received the same consideration and rank as a lawn or garden of flowers, provided it showed the effects of culture, design, neatness and care. And, while this may appear to some a very general classification, it must be borne in mind that the fundamental idea of the founder of the movement is to encourage the people in an effort to develop neat, healthful and sanitary surroundings, to abolish the ash heap, the rubbish pile and the tin can. If a miner is of practical mind and sees greater value in cabbages than grasses or flowers, he has the privilege of planting cabbages and of being qualified to enter the contest. His standing, when the judges make their awards, will be equal to that of the man who cultivates a lawn or plants flowers.

Of the miners who competed, the following received prizes:

Second and Third Prize Winners at Ravenswood, Colo.
Robert Nelson (Second Prize) Joseph Watson, Sr. (Third Prize)

Chandler
First prize, $25, Gus Hutter, House No. 47.
Second prize, $15, Jos. Cherry, House No. 39.
Third prize, $10, W. H. Mulnix, House No. 8.
Edward McMullen, judge.

Delagua
First prize, $25, Mrs. Jas. G. Young, House No. 458.
Second prize, $15, Nick Martella, House No. 471.
Third prize, $10, John Ban, House No. 460.
E. C. Stream and W. Givens, judges.

Hastings
First prize, $25, Mrs. R. Roberts, House No. 6.
Second prize, $15, W. H. Cunningham, House No. 96.
Third prize, $10, W. H. Rinker, House No. 111.
E. C. Stream, judge.

Ravenwood
First prize, $25, Wm. S. Smith, House No. 56.
Second prize, $15, Robert Nelson, House No. 52.
Third prize, $10, Jos. Watson, House No. 62.
Prof. I. E. Stuttsman, judge.

PRIZE WINNERS AT THE SECOND ANNUAL CONTEST AT DELAGUA, COLO.
Mrs. James G. Young (First Prize) John Ban (Third Prize)

On the remaining properties of the company, on account of the scarcity of water and other local conditions, no contests were held.

The Union First-Aid Meet at Charleroi

The fourth annual outing of the miners of subdistrict No. 3 of district No. 5, United Mine Workers of America, was held at Eldora Park, Charleroi, Penn., on the afternoon of Aug. 22 and the miners participated in some first-aid contests.

In the open and closed events the Toms Run Mine team of the Pittsburgh Coal Co. won first place with a percentage of 98 in the open, and 99 in the closed event. The winning teams received silver loving cups to hold till the honor is wrested from them. It will take three victories to entitle a team to permanent possession.

In the open event seven teams were entered. The contest was close and the Toms Run team, with Michael Quinn as captain, only beat the Cokeburg team of the Ellsworth Colleries Co. by a fraction of a point. The team from Cokeburg, under the captaincy of Albert Roth, made a mark of 97⅞ per cent.

The Toms Run team was not so narrowly victorious, however, in the closed event. The Ellsworth team took second honors in this contest under the captaincy of Fred Gulick. It earned a percentage of 96.

Cups and individual gold and silver medals were presented by President Van Bittner of District No. 5. Prof. E. E. Bach of Ellsworth was marshal of the contests, and the judges were Dr. G. H. Hays, Dr. R. V. Stewart, Dr. H. F. Bailey, all of Monongahela, and Dr. J. V. Wilson, of West Elizabeth. The recorder was W. L. Manice, of Pittsburgh.

About 5000 miners and their friends were present to witness the events of the day. The chief speakers at the meet were James W. Paul of the United States Bureau of Mines, Philip Murray of Monongahela and President Van Bittner. At the last moment Dr. J. A. Holmes, chief of the United States Bureau of Mines, sent word from New Mexico, that owing to ill health he was unable to be present and address the meeting.

The Ellsworth Liquor Problem

Much interest was evidenced in the courts of Washington County, on Aug. 15, when the grand jury presented to the court a petition, asking for permission to investigate in detail the charges that the Ellsworth Collieries Co. and prominent men were fostering violations of the liquor laws at Ellsworth and Cokeburg, leading coal towns in the bituminous region.

The court refused to do as petitioned, on the ground that the petition was irregular, and that if such violations existed those aware of them should lay their complaint before the duly appointed officers. The court also declined to grant the petition that the grand jury investigate the possible violations of the law by the coal company.

In the petition regarding the coal town, it was alleged that the Ellsworth Collieries Co., backed by the Lackawanna Steel Co., the Bentleyville Brewing Co. and the Charleroi Brewing Co., and E. E. Bach, sociological superintendent of the Ellsworth Collieries Co., who is recognized as an expert in this work, had conspired to violate the law. It was pointed out that the towns of Ellsworth and Cokeburg were denied liquor licenses at the last term of license court. At that time, when evidence was being heard in favor of license applicants for the two towns, E. E. Bach, the sociological expert, made an extended statement to the court and attorneys, in which he dwelt upon the difficulty of regulating the liquor business in a mining town, and emphasized the necessity for a well ordered and carefully regulated tap house or similar institution.

He gave some details about the liquor-order business, regarding which the grand jury is now making complaint. The jury classes beer agents as "devices to evade the law." The court, however, stated it had not the power to grant such a license as that desired, and since that time it is understood Ellsworth and Cokeburg miners have been getting their beer through an agency which the grand jury states is under the supervision of Mr. Bach.

He who has lost his reputation, is a dead man among the living.

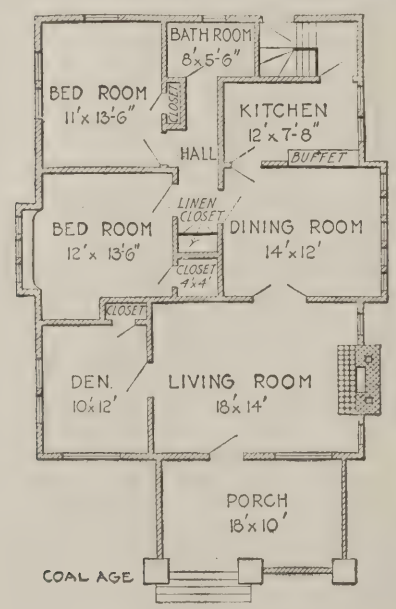
Mine Houses

If the mine owner knew what the public thinks of the average mine house, he would refuse to let his mining engineer or his building contractor do any more designing. And this applies not only to the small companies, but to the large. The buildings are all of the same type of unattractiveness, and money is rarely saved in a degree commensurate with the monotony which has to be endured. And when an attempt is made to plan houses of different design, there are only a few, at most three designs, and the effect is still dissatisfying.

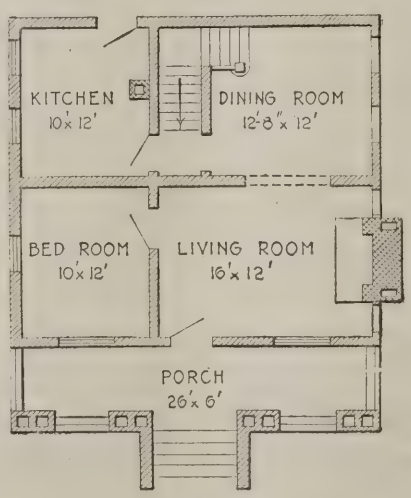
The same is as true of material as of appearance. The mining engineer is not an architect. He has some knowledge of siding, flooring, lathing, plaster and shingles, and he usually satisfies himself with this. But new material and new methods are on the market. What are good and what are bad, he has no chance of knowing, and what is more, he is afraid to take the risk of recommending them to the operator in case of failure. He consequently plays safe and builds on old lines, thus avoiding responsibility.

Buying Houses "Knocked Down"

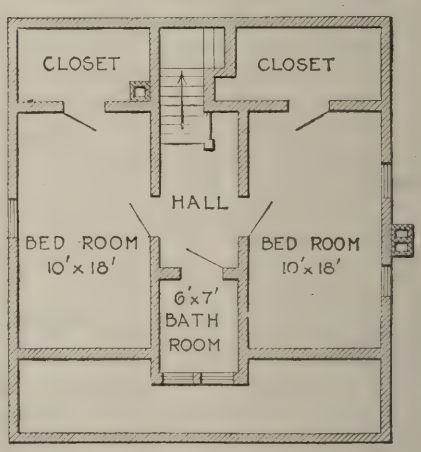
For this reason, it might be well to select the houses for a town from a catalog and have the materials shipped. There are places, of course, where the freight rates would make this prohibitive, but to save this the North American Construction Co. ships every piece cut, so there is no waste. The saving in lumber from this method is also an item, and the cost of carpentry is reduced, for all the sawing is by machinery. The waste of lumber in an ordinary building is claimed to be 18 per cent. of the whole lumber bill. Everything is planned in these houses so that waste will be avoided, and as all parts are purchased or manufactured in large quantities, the manufacturer of the houses should be able to supply them at reasonable cost ready for erection.



We would advise the coal operator to send to the North American Construction Co., Bay City, Mich., for a copy of "Aladdin Houses." Even if he decides against a purchase, the book in itself is full of interesting suggestions.



A Comfortable Bungalow with Modern Conveniences



A Two-Story Cottage

Plan of Bungalow

Ground and Second-Floor Plans of Cottage

Long spans in high tension current transmission lines cannot always be made with copper cables, since hard-drawn copper has a strength of only about 50,000 lb. per sq.in. When it is necessary to cross over rivers, lakes or bays with power transmission lines, the current may be conducted through an extra galvanized strand of special steel wire of such size and strength as to possess a factor of safety of at least five. In fact, an entire power transmission line of extreme high potential could be economically constructed with extra galvanized Siemens-Martin strand, the adoption of which in place of copper cables would reduce the number of supporting towers, which are frequently the cause of energy loss and trouble.

The Labor Situation

SYNOPSIS—Much pressure is being exerted by the merchants of eastern Ohio to bring about a labor settlement, and as a result a conference has again been called, though with little hope of a result. The Paint Creek Collieries Co. has a strike involving all its men.

In eastern Ohio, the merchants have been urging a further conference of operators and miners, alleging in the letters to the latter that by reason of the credits extended, the merchants have borne the brunt of the battle.

So conferences have been resumed at Wheeling, W. Va. The Pittsburgh scale is suggested as a compromise basis for settlement. It is said that both parties are willing to accept an exactly equivalent scale, but, as we said last week, there is little evidence of this willingness on either side. The operators desire as liberal terms as the Hocking Valley miners have granted, while the men desire a virtual increase over last year's scale. But both sides proclaim their adherence to the principle that there is no increase or decrease of wage demanded, and try in that manner to obtain public confidence.

Father McEachen's Appeal

The extent to which the public is being brought into the controversy may be judged by the fact that Father Roderick McEachen's lucid statement of the miners' case has been circulated in galley form to the press. The appeal is largely for larger wages in general for miners and for the run-of-mine law; the justice or injustice of the equivalent as offered by the operators is not considered. In fact, we believe we represent the views of the writer in saying that if he had his way, the price would be doubled.

One of his interesting arguments, however, for the equivalent as the miners would have it, is as follows: "For the past 20 years, the screenings have been rated in all the agreements between miner and operator as two-sevenths of the total coal mined. The companies sometimes took a certain amount of coal for their own use. This was not screened. For this they always paid five-sevenths of the screened-coal price. Hence the miner has always worked upon the theoretic basis that five-sevenths of his coal was lump and two-sevenths screenings. Upon this basis, the present rate of mining should be 71c. per unscreened pick-mined ton and 49.64c. per unscreened machine-mined ton. Since, however, the actual amount of screening was greater than 28 per cent. in some districts, the miners made a compromise. They averaged the amount of screenings at 32 per cent. Upon this they base their price of 47c. per unscreened ton of machine-mined coal."

The Other Side

We would point out to the divine, and his statement shows his willingness to admit that the amount of coal, thus paid for at a rate of five-sevenths of the lump coal, comprised but a small portion of the whole product. Any injustice to the operator in the rating of this small quantity of coal could be borne, as it was not likely to cause bankruptcy or any marked exclusion from markets. Moreover, much of the coal mentioned was probably sold to local wagon trade and was marketed at a really fair profit. It is a different proposition to apply this to the whole product, especially to that part where competition is more fierce.

Moreover, we wish to point out that his reference to the price at the market is not a matter at point, unless freight rates and profits to retailers are considered. If the coal trade is groaning under excessive freights and high charges for retailing, the mine operators are only chargeable with their own shortcomings, not with those of railroad men and dealers whose iniquities, if iniquities they are, they are powerless to control.

The operators, in a published statement, invite an inspection of their payrolls that the public may know that the miners are not underpaid. They make the statement that in the first half of July, 1913, the average wages of the loaders of the Roby Coal Co. for each day worked were $3.75 per day. In the second half of that month they were $4.65 per day. The earnings in the first half were reduced by the reduction in tonnage due to a national holiday. Naturally, the operators strenuously object to rumors that miners in eastern Ohio make only a dollar a day.

Conditions in Eastern Ohio

The fans and pumps were restarted at the Fort Pitt mine on Aug. 26. While the engineer at the mine on the 26th was investigating, gas in the engine room exploded, but no harm was done. The mine is full of water, and it will be about six weeks before the workings will be in running order. The pumps have been idle for an equal length of time.

The Coalburgh Coal Mining Co., on Aug. 20, and on Aug. 21, the Bixler & Ohio Coal Co., both of Baileys Mills, near Barnesville, signed the scale agreeing to pay 47c. for machine-mined run-of-mine coal. It is hardly a sufficient defection from the operators' ranks to show even a tendency. The shutting down of the Blockhouse mine, as announced last week, is as reliable an indication in the other direction.

It is understood that Charles I. Albasin, the subdistrict president in eastern Ohio, has secured a large loan from the Illinois operators, by means of which the miners in his subdistrict can continue the resistance to the demands of the operators.

That part of the Pomeroy Bend field which failed to arrive at a settlement in the earlier negotiations, as mentioned in our issue of Aug. 22, p. 299, has now signed up, a compromise having been arranged. In the Bergholz district, an understanding has been reached, but notwithstanding that fact, some of the mines are still idle.

West Virginia Troubles

The Paint Creek Collieries Co. again has a strike at its mines, involving this time seven collieries, Mucklow, Wacoma, Banner, Tomsburg, Hickory Camp and Briar Creek. The mines employ from 1000 to 1200 men. The cause of the suspension—for the miners do not call it a strike—is the failure of the company to make its semimonthly pay at the appointed time.

The miners of the Four States Coal Co. mine at Dorothy, W. Va., in the Coal River field, have withdrawn their demand for an increase in wages, according to Thomas Cairnes, the president of the district (No. 17). The men are still demanding a modification of certain working rules, the check-off and some other concessions. The miners are hopeful that the management will grant their demands.

Governor H. D. Hatfield, acting as an umpire, has decided that the New River and Winding Gulf board of arbitration can hear complaints made by persons who are not themselves aggrieved, but who present the grievances of other parties. It is not necessary for those who are entitled to relief from onerous conditions to bring charges against their employers.

Colorado Labor War

In answer to our inquiry, we learn from W. W. Wothuspoon, major-general, chief of staff, of the War Department, that the men recently hired who are allowed to work for coal companies in Colorado, must be residents of the state, and further, that the order does not specify that they must be citizens. The statement made editorially that all "recently hired" miners must be citizens was taken from an apparently verbatim copy of the notice said to be posted by T. Waterman, lieutenant-colonel, 12th cavalry, at mines in the Boulder-Louisville district. A letter appeared in the "Rocky Mountain News" containing this document as part of its contents. Inquiry is being made as to the correctness of the quotation.

Governor Ammons, of Colorado, after 88 days' delay, has made public the findings of the court-martial regarding the militiamen who took part in the action at Ludlow. Twenty-one men were tried and have been completely vindicated.

The United Mine Workers of America are about to ask the civil courts to declare the court-martial illegal, and to bring the soldiers to trial on charges of murder. Only by changing the venue is there any possibility of the courts finding the soldiers guilty, for the unanimous opinion of the law-abiding public in southern Colorado is that the union has fallen into bad hands and that the militia merits public approval and acclaim.

Twenty prisoners are in jail in Trinidad for offenses alleged to have been committed in the Colorado mine war. William Diamond, a national organizer of the United Mine Workers; James Davis, marshal at Aguilar; Frank Miner, president of the Trinidad Trades Council, and Robert Uhlic, former president of the Trinidad Miners' Union, are among the prisoners.

The federal troops have arrested Helen Schloss, of Denver, for picketing. She was in charge of the miners' hospital at Ludlow.

Discussion By Readers

Gasoline Mine Locomotives

In the answer to the question, "Is there any danger in the installation and use of a gasoline motor in a mine," COAL AGE, Aug. 29, p. 358, it is stated among other details that "A gasoline motor is not an ideal motor for use in a coal mine." The answer goes on to state that "the discharge from such a motor rapidly vitiates the mine air; . . . . the handling of a highly explosive oil, as gasoline, is always a dangerous factor in a mine, owing to the liability to fire or explosion; . . . . the danger of their use is greatly increased by the possibility of a mine wreck when the gasoline tank might be injured and its contents take fire."

I want to say that experience in the development and construction of this class of motor has made it an ideal machine for use in a coal mine. As is true for every other type of haulage locomotive designed for mine use, the success of the gasoline motor depends much on the conditions of service. The gasoline motor has a great many advantages that recommend it for mining use, chief among which are its ability to operate in deep-vein coal mines; in mines with low roofs; under bad roof; in wet mines; on heavy grades; and, last, but not least, in mines which are so gaseous that an electric locomotive could not be installed with safety. This type of locomotive possesses, also, the additional advantage of being able to go anywhere on the main roads and extensions, without incurring the additional expense for wiring or piping, which is necessary in the use of either electric or compressed-air motors.

The further statement that the exhaust from a gas-driven engine vitiates the mine air is not true when this type of locomotive is used for haulage on main or cross-entries, because the exhaust has now been deodorized so that it is not perceptible in a mine where these locomotives are installed. The odor of the gasoline cannot be detected even in the main-return entries of such mines. The only reason that the motors cannot be used for gathering work in rooms or chambers is that the carbon monoxide given off in the exhaust requires to be diluted by an air current in order to render it harmless.

Again, referring to the statement in reference to the danger from fire in case of a mine wreck, permit me to say that, in the improved type of gasoline locomotive, the gasoline is carried in steel, indestructible tanks. The tank is filled and sealed on the surface, and is then taken into the mine and placed on the locomotive when the mine is idle, the other tank being at once removed and taken to the surface to be filled. There is practically no danger of this tank being damaged in a mine wreck, owing to its being located on the locomotive, in such a position as to withstand any kind of a blow.

In closing, permit me to briefly summarize the important advantages of this type of locomotive as follows:

1. Because the gasoline locomotive is a self-contained unit, it does not require for its operation a power house and coal pile; extra boilers; a compressor or generator; a high-pressure pipe line and charging stations; feeder and trolley wires, rail bonds and other electrical connections and equipment, including a specially well laid track, to preserve the bond connections intact; or any separate traveling ways for men and mules, to avoid contact with live wires.

2. Because the gasoline locomotive is a self-contained unit, the following results are obtained in its use: When the locomotive throttle is closed, all expense of operation stops; boilers do not have to be kept under pressure all day to enable the locomotive to handle a few trips at varying intervals; each locomotive generates its own power according to the work it has to perform, which avoids the waste common to other systems, due to generating more power than is actually required; as the length of haul increases, there is no extra expense required for extension of pipe lines or feed and trolley wires.

In my opinion, these advantages are sufficient to recommend the use of gasoline locomotives in coal mines, under such regulations and restrictions as are necessary to eliminate the dangers to which reference has been made.

E. W. HAMILTON, Engineer,
Milwaukee Locomotive Mfg. Co.

Chicago, Ill.

The Foreigner in Mining

Letter No. 3—Mr. Bailey's letter, in reference to the need of educating the foreign element, so largely represented in the coal-mining industry, today, COAL AGE, Aug. 22, p. 315, is interesting, pertinent and suggestive, not only to the coal industry but to the American people at large.

It is clear that the unrestricted tide of emigration from Latin-European countries has foisted upon the American national existence an element whose principles of social, political, industrial and religious life are antagonistic to the basic principles upon which American institutions are founded.

The assimilation and amalgamation of this class as an integral part of American social life could, under ordinary circumstances, be effected by the second method suggested by Mr. Bailey, were it not for the fact that, as a class, they possess a dominant characteristic that is the result of centuries of association with a type of civilization that is wholly un-American, and that forms an insuperable barrier to education along the lines suggested. It is unnecessary to be more specific with respect to the nature and origin of this characteristic trait, as the careful student of race peculiarities will readily perceive the nature of the charges made.

Coming from lands of restricted personal liberties, to a country where the highest degree of freedom consistent with the maintenance of order and the preservation of rights, is assured, it is natural to suppose that these privileges would command their respect and veneration. In-

stead, however, these people regard liberty as unrestricted freedom for the indulgence of the animal propensities of primeval man.

The law under which they have been raised is a menace to their own physical and spiritual life, impelling them to the cultivation of cunning, subterfuge and duplicity—qualities that are not merely detrimental to but destructive of the only element in man, the cultivation of which will elevate him to the high plane of life that his creator designed him to occupy.

While it is true that every normal human being is endowed with the faculty of reason, it is equally true that if this faculty be restricted in its operation, the moral nature of man will become useless as a factor in the attainment of civilization, which is the measure of the standard of morality for every individual, nation or race. Though an individual, nation or race may cultivate physical and mental qualities so as to become giants in these respects, they are no farther advanced in civilization than primitive man. If this is not true, why are the so called civilized nations of Europe engaged in the most barbaric struggle of destruction that has ever disgraced the history of mankind?

The instruction of these people and the cultivation of their mental and moral natures is not, in my opinion, the question that confronts us. To do that is, I believe, an impossibility. That which is in a state of adolescence can be educated and trained, but that which is perverted is beyond redemption. If it were possible to completely separate these people from their environment; disabuse their minds of their perverted ideas of justice, morality and law; demolish the superstitions that constitute the barriers to progress, there would be a possibility of inculcating in them the principles of freedom that form the basis of our social institutions. The task is more than herculean; it is impracticable and the time and labor devoted to its accomplishment is energy wasted.

Many foreigners come to our country with no intention of making themselves American citizens, or submitting themselves to American laws; and, although some go through the formality of taking out naturalization papers, many regard it as an intimation that our customs and institutions are superior to their own. Is this not the case? For the most part, they make no effort and express no desire to be educated in our methods of government. They import their customs and, taking advantage of the extreme liberality of our laws, graft them upon American institutions. The governments of which they are representatives, in their efforts to oppose the establishment of representative governments in Europe, have indelibly impressed upon the minds of the people that earthly rulers exercise their authority by divine appointment.

Such a subversion and enslavement of the masses could be accomplished only by the connivance and coöperation of the ruling powers in state and church. The method adopted was to limit or restrict education; to subjugate the mind by encouraging belief in the supernatural; and to impress upon the mass of the people, by spiritual instruction, the idea that they occupy an inferior position in life through divine will.

Such is the education and training of the people we are importing without restriction and injecting into the industrial and social life of this country. Well may we ask, are they a menace to our social, political and industrial welfare? This question needs no better answer than the incidents quoted by Mr. Bailey in his letter; but if further evidence of the danger is required it may be found in the fact that the sentiment of this class toward our institutions has already been recognized by the introduction of a bill in our national congress, providing for a stringent regulation of immigration along lines in accordance with the facts I have rehearsed. As a rule, our legislators are slow to perceive the existence of a serious or critical situation and when they do recognize such fact the public at large can take it for granted that the conditions actually exist.

Let me say, then, that Mr. Bailey's first suggestion is the only practical solution to the question; namely, "the exclusion of the morally uneducated and mentally undeveloped immigrant." If such a bill could become operative, as a law, there would certainly result a termination of immigration from these countries, since such a qualifying condition would exclude both the governed and the governing classes—the first through being morally perverted, and the second by being moral pervertors.

I. C. PARFITT.

Jerome, Penn.

Letter No. 4—I was much pleased, in reading this week's issue of COAL AGE, to note the great interest taken in the foreign-speaking miner. Truly, there is no subject that should interest the mine foremen of this country more than that of the foreign-speaking miner who, it must be acknowledged, is here and here to stay.

So often we hear the remark, "They all want shipping back to the old country." But, anyone making such a remark simply does not know what he is talking about. It must be remembered that, in coal mining, we depend almost wholly on this class of labor; and, take them as a whole, they are good workers. The better they are treated, the better men they become. I know this to be a fact by experience, having dealt with them for a number of years. I have taken these men right into the mine, as they come from the old country fresh from following the plow, and have watched them grow to be good miners and good citizens generally.

I acknowledge that the majority of this foreign element employed in the mines are illiterate and come from the lowest classes in their respective countries where they never had a chance. On coming to this country, their conditions are so much changed that it often proves too much for them. The man who has been brought up from his boyhood, on the farm where he has found it barely possible to make both ends meet, and has rarely had the sight of money, finds himself almost bewildered on coming to this country and receiving his first pay of a few dollars. Could we put ourselves in their place and imagine that we were in a strange country where we could not see a familiar face or understand a word spoken and where the ways and customs were wholly different from those to which we were accustomed, we would have more sympathy for them in their present situation.

It is, of course, often annoying and very trying for a busy foreman to be obliged to explain a simple thing, in a number of different ways, before he can make them understand what he wants to tell them. But, as foreman, it matters not what these men want to say, I always hear them and, though it takes considerable time and trouble, I try to give them an answer and make them understand. I have always noticed that they are quick to appreciate this treatment. Another feature of the foreigner, is that

he is quick to notice any favoritism shown to another. For this reason, I try to treat all alike. I have noticed, also, it is a hard matter to regain their confidence if this is once lost. A foreigner seldom forgets an injury.

The foreword, COAL AGE, Aug. 29, p. 329, contains much truth in regard to the treatment of miners; but I think this refers more to the mine foreman than to the timekeeper. Where a timekeeper is asked one question by these men, the boss is asked 50 or more; and it is even more important for him to give a civil answer in return, than for the timekeeper who is not responsible for their work. What sounds better than to hear a boss, when going into a place, sing out, "Good morning, boys, what is it going like today." Such a kindly greeting of the boss encourages the men and makes their troubles lighter because of the interest shown in their welfare.

In the daily visits of the boss, to the working places of the men, many matters come up for him to decide; and it is hard for him to know what to say or do, as between the men and his employers. If, however, he is guided by a kind heart. He is sure to come out right in the end. When a man has done something that is wrong, it is generally easy to tell whether he did so, knowingly, or acted in ignorance; but, in either case, no good will come from calling him hard names. Talk to him quietly and show him his mistake and the danger.

In closing, let me say, never be above speaking to your men as you meet them. It pleases them to know that you remember their first name. Because a foreman's wife is with him is no reason why he should not speak thus familiarly to the men he meets. Nothing is more pleasing to them than to be recognized at such times. While giving men all the liberty possible, a foreman should not fail to respect his position, for by that means he will be respected. The American foreign-speaking miner seldom fails to respect his boss when properly treated.

THOS. HOGARTH.

Heilwood, Penn.

Thomas R. Pierce

[Contributors to the Discussion Department will regret to learn of the death, July 9, of Thomas R. Pierce, Scranton, Penn. Mr. Pierce had worked in the mines from a boy. By his devotion to his work, he had contracted disease that, for 19 months previous to his death had kept him out of the mines. His spare hours were spent in reading and writing. His article on The Coal Miner, COAL AGE, Aug. 29, p. 355, published before learning of his death, was one of his best productions, as was also his article on Working Coal under Sandstone Cover, Letter No. 10, COAL AGE, Vol. 4, p. 949.—ED.]

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

Drainage—Economic mine drainage requires such a disposition of the openings driven in the seam for the extraction of the coal, including all passageways, headings and chambers, that the water coming from the strata will flow by gravity, either to the main sump at the shaft or slope bottom, or to certain gathering centers from which it can be readily siphoned to the main sump or pumped directly to the surface.

In practically level seams or seams having slight inclination, the question of drainage does not materially affect the general mine plan. In this case, good roadside ditches afford the necessary waterways by which the underground water flows to the sumps provided to receive it. Such sumps or catch basins are located at one or more convenient low places or "swamps," in the mine, where it is possible to install a pump of sufficient size to handle the water of that section at all times.

The rooms or chambers, in practically level seams, are turned off both entries of a pair, which greatly reduces the expense of entry driving and necessary maintenance of roadways and air courses.

In inclined seams the direction and amount of pitch are controlling factors in determining the general plan of the mine, in respect to the course of main roads, cross-headings and rooms or chambers. In respect to drainage, it is important to drive all such openings to the rise, in order to avoid the annoyance and expense of providing artificial means of draining the working faces.

Haulage—Economic mine haulage requires that the coal, like water must gravitate, as far as practicable, from the coal face where it is mined, to the foot of the shaft or slope opening from whence it is hoisted to the surface.

In level seams, the question of haulage does not affect the plan of mine; but, in seams of more or less inclination, it becomes a matter of first consideration.

In inclined seams, it is always possible to drive the main haulage roads in such a direction that the grade of the road will not only favor the movement of the loaded cars, but will be such that the power required to haul the loaded trip out of the mine will be equal to that necessary for hauling the empty trip back into the mine. This is called the "economical grade." (See Mine Haulage.)

The grade of any road, or the road grade, in an inclined seam, may be calculated when the angle of inclination of the seam and the angle the road makes with the strike of the seam are known, by the following rule:

Rule—The tangent of the grade angle is equal to the tangent of the angle of inclination of the seam, multiplied by the sine of the angle the road makes with the strike of the seam.

Or, calling the angle between the road and the strike of the seam, the "road angle," this angle is calculated by the use of the formula

$$\sin \text{road angle} = \frac{\tan \text{grade angle}}{\tan \text{inclination}}$$

The Coal Age Pocket Book

MINE DRAINAGE

The drainage of a mine relates to and includes all methods, means and appliances used to free the mine of the underground water that finds its way naturally into the workings and renders them unfit for work. The expression "unwatering the mine" is frequently used in respect to mine drainage, but applies more properly to the work of removing considerable quantities of water from a mine or section of a mine that is flooded to such an extent as to prevent or seriously impede the operation of the mine.

Underground Waters—The rock strata forming the crust of the earth are the natural receptacle of water that, under the action of gravity, percolates downward from the surface. By the laws of nature, there is, besides, a more or less continuous evaporation of water from the earth's surface into the atmosphere, forming mists and clouds that, again, give up their water by condensation causing the rain, snow and hail that fall to the earth.

There is thus naturally formed three distinct zones or divisions of the waters of the earth, which accordingly may be designated as, atmospheric, surface and underground, the last named being of the greatest concern in the prosecution of mining work.

Water Level—The term "water level," as applied to mining, is frequently misunderstood and its importance, therefore, not comprehended. The term has no reference or relation to the term "sea level," which is a definite term whose meaning is well understood. On the other hand, "water level" varies widely in different sections of the country, and with the change of seasons, in the same section. It is far from being a constant or definite level.

The water level in any locality is indicated, in a general way, by the average water level in the wells in that section. This level is higher in wet than in dry seasons of the year, and is modified locally by conformations of the strata forming basins and synclines more or less isolated and distinct. The term may, therefore, be defined as the natural drainage level in the rock formations.

Water-Bearing Strata—Rocks differ in their nature in respect to their capacity for holding water or permitting water to pass through them. Many of the harder, close-grained rocks of the igneous and metamorphic types, as granite, syenite, trap, and even the sedimentary shales, limestones and clays are wholly impervious to water; while the more porous and coarser-grained sandstones, sandy shales and faulted limerocks afford ample storage for large quantities of water, and permit the ready passage of water through them. These rocks are the so called "water-bearing rocks" of the coal formations.

Effect on Mining—The water-bearing strata form the great underground storehouses and waterways or channels by which the water enters the mine. The rocks themselves, particularly the softer calcareous rocks, carbonates and sulphates, are disolved, disintegrated and worn away by the water, and larger channels and crevices are formed in which the water accumulates under great pressure.

Inquiries of General Interest

Problem in Algebra

While thanking you much for the trouble taken in answering my question, COAL AGE, Aug. 29, p. 357, permit me to ask if there is not a misunderstanding somewhere in this problem. I understand that the conditions stated assume that B changes his rate by increasing it $47^3/_7$ yd. per min., *after* meeting A. By this understanding of the question, the results given in the answer, p. 357, do not prove out. I should be glad to have a further explanation.

STUDENT.

Lincoln Place, Penn.

The statement of the question is somewhat ambiguous. The solution given on p. 357, assumes that B must increase his rate $47^3/_7$ yd. per min. over the entire course, in order to make the rate a "dead heat." We agree with correspondent, however, that the probable meaning of the question is, as he states, that B changes his rate *after* meeting A. We give below the solution of the problem on this assumption.

The question reads as follows:

"A," in running a race with "B," to a post and back, met him 10 yd. from the post. To make it a dead heat, B would have to increase his rate 47 3/7 yd. per min. But, if without changing his pace B had turned back on meeting A, he would have reached the starting point 4 sec. later than A. What is the distance from the starting point to the post

Solution—Let x = the required distance from the starting point to the post, in yards. Then, in the first stage of the race, A runs $x + 10$ yd., while B is running $x - 10$ yd. If, now, without changing his pace, B turns back on meeting A, he reaches the starting point 4 sec. or $^1/_{15}$ min. later than A. The first step in the solution is, therefore, to find the amount A gains on B in the second stage, from knowing the gain (20 yd.) in the first stage.

Since both A and B, in this case, keep the same pace after, as before meeting, and A runs $x + 10$ yd. before and $x - 10$ yd. after meeting, the distance (d) gained in the second stage is found by the proportion

$$(x + 10) : (x - 10) :: 20 : d$$

$$d = \frac{20\ (x - 10)}{(x + 10)}$$

If B goes this distance in $^1/_{15}$ min., his rate of running is as follows:

B's first rate,

$$\frac{15 \times 20\ (x - 10)}{(x + 10)} = \frac{300\ (x - 10)}{(x + 10)}\ yd.\ per\ min.$$

Now, assuming that B increases his rate, at the moment of meeting A, $47^3/_7$ yd. and, by this means, the race is a "dead heat"; he must run $x + 10$ yd. at a pace of,

B's second rate.

$$\frac{300\ (x - 10)}{(x + 10)} + \frac{332}{7} = \frac{347.43x - 2525.7}{(x + 10)}\ yd.\ per\ min.$$

It is necessary, now, to find A's rate, which is unchanged throughout the race. Since, in the first stage, A runs $x + 10$ yd. while B goes $x - 10$ yd., these distances being proportional to their respective rates, A's rate is found thus,

$$(x - 10) : (x + 10) :: \frac{300\ (x - 10)}{(x + 10)} : A's\ rate$$

$$A's\ rate = \frac{300\ (x - 10)}{(x + 10)} \times \frac{x + 10}{x - 10} = 300\ yd.\ per\ min.$$

Finally, in the second stage of the race, when B runs $x + 10$ yd. while A is going $x - 10$ yd., the distances being proportional to the respective rates,

$$(x + 10) : (x - 10) :: \frac{347.43\ x - 2525.7}{x + 10} : 300$$

$$(347.43\ x - 2525.7)\frac{x - 10}{x + 10} = 300\ (x + 10)$$

$$(347.43\ x - 2525.7)(x - 10) = 300\ (x + 10)^2$$

$$47.43\ x^2 - 12{,}000\ x = 4743$$

$$x^2 - \frac{12{,}000}{47.43}\ x = 100$$

$$x = 253.4\ yd.$$

Distance to post.

Other values are as follows:

B's first rate,

$$\frac{300\ (x - 10)}{x + 10} = \frac{300 \times 243.4}{263.4} = 277.22\ yd.\ per\ min.$$

B's second rate,

$$277.22 + 47.43 = 324.65\ yd.\ per\ min.$$

Time, first stage,

$$(253.4 + 10) \div 300 = 0.8780\ min.$$

Time, second stage,

$$(253.4 - 10) \div 300 = 0.8113\ min.$$

Total 1.6893 *min.*

The proof of this solution is the following:

By A, $300 \times 1.6893 = 506.8\ yd.$

By B, one pace,

$$277.22\ (1.6893 + 0.0667) + 20 = 506.8\ yd.$$

By B, two paces,

$$277.22 \times 0.878 + 324.65 \times 0.8113 = 506.8\ yd.$$

Draining Mine Sump

Referring to the answer given to the examination question, COAL AGE, Aug. 22, p. 318, in regard to the time required to drain a mine sump, which is found to be 5 hr. 5.7 min., I do not understand how 28.274 sq.in. divided by 144, which is the number of square inches in a square foot, can give 19.63 cu.ft. How is it possible for square inches divided by square inches, to give *cubic feet?*

CONSTANT READER.

Latrobe, Penn.

Correspondent should have given his name when writing, so that this simple oversight on his part could have been answered by mail. He has overlooked the multiplication by 100 ft., which gives cubic feet.

Examination Questions

British Columbia Examination, May 20, 1914

(*Selected Questions*)

Ques.—Is firedamp compressible? What effect has a decreased pressure of the atmosphere on this gaseous mixture?

Ans.—All air and gases are compressible. Any decrease in atmospheric pressure is accompanied by a corresponding expansion of a firedamp mixture, the expansion in the volume of the firedamp being inversely proportional to the absolute pressure.

Ques.—Which is the most difficult gas to contend with in mining? Explain fully.

Ans.—In respect to its removal, carbon dioxide gives the most trouble in dip workings and deep shafts, while marsh gas often gives serious trouble when generated in volume in rise workings and at the face of rise headings. In respect to explosive conditions in mines, marsh gas and carbon monoxide present the greatest difficulties, owing to their inflammability when mixed with air in certain proportions.

Ques.—What precautions would you adopt to prevent loss of life and property in mines subject to sudden outbursts of carburetted hydrogen gas?

Ans.—An ample circulation of air should be maintained, and this should be so conducted and distributed throughout the mine as to ventilate thoroughly all passageways and working places, as well as the waste and void or abandoned places, in every portion of the mine. To guard against accident, duplicate ventilating fans should be installed. Only safety lamps of approved pattern should be used. Every precaution should be taken to prevent the accumulation of dust, by loading out all fine coal and slack and using only dustproof cars.

Permissible powder should be used, and strict regulations should be enforced in reference to blasting. All shots should be inspected and fired by competent persons. The mine should be equipped with an efficient signal system. Due attention should be given to the system of timbering, with special reference to protecting the working faces against the pressure of the gas where this is in the roof or coal. The method of mining the coal should also be given careful attention, to avoid accident from the same cause.

Ques.—A mixture of marsh gas and air, at its most explosive point, is passing along an airway 4x5 ft., at an average velocity of 500 ft. per min. What quantity of fresh air must be added to this current so that the gas cannot be detected on a safety lamp?

Ans.—The answer to this question will depend on the safety lamp used, and the ability of the observer to discover the flame cap on the lamp. Using the unbonneted Davy, burning sperm or cottonseed oil, it may be assumed that the gas in the air current will not exceed 2 per cent. and escape detection, in ordinary mining practice. The volume of air and gas in this airway is (4x5) 500 = 10,000 cu.ft. per min. A firedamp mixture, at its most explosive point, contains 9.46 per cent. of gas. The volume of gas, in this case, is, therefore, 10,000 × 0.0946 = 946 cu.ft. per min. If this volume of gas is 2 per cent. of the return current after the air is added, the total volume of the current will be 946 ÷ 0.02 = 47,300 cu.ft. per min. The volume of air to be added, therefore, to produce this result, is 47,300 — 10,000 = 37,300 cu.ft. per min.

Ques.—How far can a pair of entries be driven before a cap will show on a safety lamp, if an air current of 4000 cu.ft. per min. is passing in the entries, assuming that the coal gives off 1 cu.ft of marsh gas in every 90 ft. of each entry? Give the proportion of gas and air in the mixture.

Ans.—The answer to this question will depend upon the lamp used for the detection of gas and the ability of the observer to discover the flame cap. Assuming that 2 per cent. of gas can be detected by the use of the unbonneted Davy, the air in this current of mixed gas and air would be 100 — 2 = 98 per cent. In this case, therefore, 4000 is 98 per cent. of the mixture and the entire volume of gas and air is 4000 ÷ 0.98 = 4081.6 cu.ft. per min. The volume of gas that must be given off by the entries in order to produce this condition is, then, 4081.6 — 4000 = 81.6 cu.ft. per min.

Now, if 1 cu.ft. of marsh gas is generated in every 90 ft. of each entry or 2 cu.ft. for every 90 ft. of the pair of entries, the quantity of gas given off is 1 cu.ft. for each 45 ft. of the pair. To generate 81.6 cu.ft., on this basis, would require 81.6 × 45 = 3672 ft., which is the distance a pair of entries can be driven under the assumed conditions.

Ques.—A pair of entries 300 ft. long have five crosscuts connecting them at 60 ft. apart, the pillars between the entries being 30 ft. wide. These entries and crosscuts are all filled with marsh gas (CH_4). If an air current of 6000 cu.ft. per min. is available, what is the least time that will be required to clear out this gas, without fouling the air current further than to cause a small cap on a safety lamp? All the places mentioned are 8 ft. wide and 5 ft. high.

Ans.—The five crosscuts, each 30 ft. long, represent a length of 5 × 30 = 150 ft., which added to the length of the two entries gives 2 × 300 + 150 = 750 ft. of length. The cubical contents or volume of these entries and crosscuts is, then, 750 (5 × 8) = 30,000 cu.ft. Now, assuming the "small cap" represents 2 per cent. of gas in the current of air and gas, the volume of pure air is 100 — 2 = 98 per cent. of the mixture. On this basis, the total volume of the return current of gas and air is 6000 ÷ 0.98 = 6122.4 cu.ft. per min.; and the volume of gas drained off is then 6122.4 — 6000 = 122.4 cu.ft. per min. Making some allowance for the difficulty in draining the gas, it would be safe to assume that the air current carries off, say 120 cu.ft. of gas per min. On this basis, the time required to drain these entries and crosscuts would be 30,000 ÷ 120 = 250 min., or 4 hr. 10 min.

Coal and Coke News

Harrisburg, Penn.

Four of the big railroad companies, operating in the bituminous region, and representing the Central Freight Association, conferred with the Public Service Commission on Sept. 1, regarding increased freight rates in the western part of the state, as granted by the recent ruling of the Interstate Commerce Commission.

George D. Ogden appeared for the Pennsylvania R.R., F. Y. Sladden for the Pittsburgh & Lake Erie; F. C. Baird for the Bessemer & Lake Erie and T. J. Walters for the Baltimore & Ohio. These men asked the Public Service Commission to grant blanket permission to all roads publishing Pennsylvania interstate rates to cancel all tariffs now under voluntary suspension effective on or before Sept. 12, and also asked authority to republish the five per cent. rates as modified by the order of the Interstate Commerce Commission on less than statutory notice of three, five or ten days, or to observe the same number of days' notice as may be granted by the Interstate Commerce Commission.

The commission agreed as to the withdrawal of the present rates but reserved its decision regarding the proposition to make effective the five per cent. increase on less than the statutory notice of 30 days. The commission also made it plain that no matter what its attitude on the latter question may be, it would not affect the question as to the reasonableness of the increased rates.

The production of anthracite coal in August was slightly larger than that of August a year ago. Most of the large producing companies report a normal tonnage, but two of them were ahead of last year's record, and the orders from Canada are reported coming in earlier, though not in greater volume, than last year. August shipments will approximate 5,400,000 tons when the official figures are published.

The labor situation continues quiet.

An interesting development is the shipment by the Lehigh & Wilkes-Barre Coal Co. of 1000 tons of egg coal to San Francisco through the Panama Canal. This is the first shipment of anthracite by this route. Anthracite has been shipped to San Francisco by boat in small quantities as ballast around the Horn, but this was a matter of months. It is estimated that it will take the Lehigh & Wilkes-Barre Coal Co.'s shipment 30 days to reach its destination.

No exodus of reservists of the warring nations is reported, although many of the mine workers are natives of them. Russians, including Poles, Lithuanians and Slavonians, predominate, and next come Italians, Irish, Austrians, and Hungarians, Welshmen, Germans and Englishmen in the foregoing order.

PENNSYLVANIA

Anthracite

Harrisburg—Mandamus proceedings were begun Aug. 3 against James E. Roderick, chief of the State Department of Mines in the Dauphin County Court by miners of the Schuylkill County anthracite district who claim that foreman's certificates have been unlawfully withheld from them. The plaintiffs aver that they took the prescribed examinations, passing them, and are now losing money because of the lack of certificates.

Wilkes-Barre—After being idle for over a week because of the damage done by a cyclone, the Stanton Colliery of the Lehigh & Wilkes-Barre Coal Co., resumed operations Sept. 1. To repair the damage to a point where the colliery could be operated, the company employed 250 men every day for a week.

Wyoming—S. J. Jennings, mine inspector for the Eighth Anthracite District, made presentment to the court recently charging Rissinger Bros., mining contractors, with violating sections of the mine law at the Troy colliery. It is claimed that Rissinger Bros. failed to construct and equipp a mine hospital outside of the colliery, also that engine houses built inside the mines were not of inflammable material. The defendants agreed to comply with the law in these respects and the court by agreement held the complaint of the mine inspector pending the elimination of the grounds on which the violation is charged.

Pottsville—A severe drought threatens to close the collieries here. Some of the coal companies in order to prevent this from taking place are making preparation to haul water for steam purposes. The Philadelphia & Reading Coal & Iron Co. is negotiating for the purchase of Lakeside, a large tract of land which would give the company possession of a considerable body of water. The Girard Estate is rapidly completing a reservoir with a capacity of 278 million gallons.

Joseph Gudonis, on Sept. 3, threw himself down the East Brookside shaft, a distance of 1700 ft., meeting death upon a cage, his fall completely severing his limbs and breaking every bone in his body. Gudonis was employed as a contract miner but quit and complaining of headache went home. A short time later he ran madly toward the shaft and dashed himself to death.

Thropp—The 1500 mine workers at the Pancoast mine of the Price-Pancoast Coal Co. declared a strike on Sept. 2. Several hundred of the workers, who were not present at the meeting on Sept. 1, when the strike was called, reported for work, but were met by pickets who informed them of the strike order. The men at once returned home. The men have two grievances, the most important being that the fire bosses have refused to remain with the union. The six fire bosses joined the organization some time ago, but recently they resigned, and efforts to get them back have been unsuccessful.

Bituminous

Connellsville—The advent of September brought no inquiry for furnace coke for the month, and it is evident that the furnaces which bought coke for July and August are covered for September also. At the present time the trend in consumption is apparently downward, undoubtedly by reason of the industrial unsettlement caused by the European War.

Fayette City—Miners to the number of 450 walked out of the Warner-Yough mine Sept. 3, because one of their number had been discharged for refusing to work in a room which had water in it. This mine has been running steadily for the past two years. Union officials from Pittsburgh hope to get the men and the company together soon. The closing of this operation leaves only two mines running at this place at the present time.

Washington—The Fidelity Title & Trust Co. of Pittsburgh, receiver for the Pittsburgh & Westmoreland Coal Co., filed suit in court recently against the Pennsylvania R.R., to recover $26,611.83 damages. In April last while cars were being placed in the Hazel Kirk mine, No. 3, it is claimed that the cars derailed demolishing a coal tipple.

Charleroi—With a number of the mines along the Monongahela River partially or entirely closed owing to the scarcity of empty craft to load, the shipments of coal down bound passing Lock No. 4 for the month of August were light. The report of the lockmaster shows that 12,648,000 bushels of coal from the mines along the upper Monongahela River were passed through the government lock during the month.

Seward—With three shifts of men working eight hours each, operations at the new plant of the Conomaugh Smokeless Coal Co. are being pushed to completion. The shaft is down now a distance of 160 ft. The John Thomas & Sons operations near Cramer are being worked to capacity and heavy shipments are being made. The Keystone Coal & Coke Co.'s mines are working four days a week instead of two or three days, as has been the rule for several months and everything indicates that a big demand for coal is in sight.

WEST VIRGINIA

Charleston—The report of a wholesale reduction of wages in the mining operations in the Norfolk & Western Field appears to have been decidedly exaggerated. As nearly as can be ascertained the rumor had its origin in the fact that in one operation a slight reduction in the wages of some of the employees was recently made in order to bring them at that particular operation to conform with those made at adjacent mines conducted under similar working conditions. There has been no general reduction either effected or in contemplation.

Wheeling—State Mine Inspector, Earl A. Henry, recently stated that the Eastern Ohio coal strike which is creating no comment in this section at the present time is not throwing much business to the mines of West Virginia. This is due

to the fact that the markets for Ohio coal are not easily reached from the mines of this state, the larger part of its production going to the Atlantic Coast while the Ohio coal is mostly sent to the Lakes.

Fayette—The contention of the Black Betsey Coal & Mining Co. and the Boomer Coal & Coke Co. that they acted in accordance with the Constitution and the By-Laws in discharging certain of their employees recently was sustained at a conference held between the excutive boards of the United Mine Workers and the Kanawha Coal Operators Association. It is stated, however, that the companies will voluntarily give employment to the men whom they discharged.

Bluefield—All coal loading records of the Chesapeake & Ohio R.R. in West Virginia and Kentucky coal fields were broken during the month of August. A total of 2,202,115 tons of coal were loaded or an increase of 140,865 tons over that loaded during the month of July. The last day of August broke all records for a single days loading and a total of 113,755 tons were handled or an increase of 3265 tons over Aug. 3 which was the previous record.

Along with new movements for a better citizenship in country, town and city, come new courses in the schools. The Concord State Normal School will this year offer a new course for the benefit of those who expect to go into mining communities to teach. The course will be offered primarily for the purpose of helping the teachers make better schools in the mining sections of the state. The course includes a study of mine gases, their properties and effect on the miner, the analysis of mine air, the use of the barometer and hygrometer, as well as the use and misuse of safety lamps. Moving pictures and lantern slides will be used to illustrate the safe methods of mining, and better means of sanitation for mining towns.

TENNESSEE

Nashville—The reduction ordered last winter by the Interstate Commerce Commission on freight rates on coal hauled from points in Kentucky, Tennessee and Alabama and by which adjustment of switching practices also was ordered, has been sustained by an opinion handed down in the Federal Court, much to the satisfaction of the commercial interests of this part of the country. J. W. Warrington, Circuit Judge, and John E. McCall and E. T. Sanford, United States Circuit Judge, signed the finding, which it is hoped is the final entry in the long drawn out coal rate and reciprocal switching case.

KENTUCKY

Barbourville—The wage scale for the union miners emproved in this section, where, however, only a portion of the mines are worked by union workmen, is due to be adjusted sometime this month. It was to have been taken up the first week in September but was postponed for later consideration. It is not expected that the adjustment will be attended with any difficulty.

OHIO

Coshocton—George Lent has started suit in the Coshocton County courts against W. A. and Daisy Hahn to secure a clear title to a tract of coal land which he leased from the defendants in March. The plaintiff says that through oversight there were no witnesses to the lease and he wants the error corrected.

Columbus—Professor Frank A. Ray, of the chair of mining engineering at the Ohio State University has just issued a publication entitled "The Ohio Coal Supply and its Exhaustion." Among other things he says that "All calculations upon the depletion of Ohio's coal supply are more or less pure speculations. Our knowledge is yet deficient and we must know more of the facts both as to the coal reserve and the future consumption before the total depletion of the Ohio coal supply can be predicted."

It is stated that hundreds of small coal mine owners who lease their property for operation will be affected by the decision of the State Industrial Commission recently announced which makes the owner liable in all cases of injury for payment of compensation. The desire of mine owners to maintain their property in good condition has resulted in most contracts being so drawn that the lessee is not an independent contractor but merely an agent of the owner.

INDIANA

Indianapolis—The International Executive Board of the United Mine Workers of America, at a recent session, passed the following resolution:

"Resolved, That we, representing more than 400,000 mine workers of North America, express ourselves as against war in any form. We are for peace and for a peaceful solution of all disputes arising among nations without resorting to arms; and be it further

"Resolved, That we commend the President of the United States for his efforts in behalf of peace. His offer of the services of our government to the warring nations of Europe as a mediator touched a responsive chord in the hearts of all peace-loving people. In like manner the tactful, wise and patriotic manner in which he conducted affairs so as to prevent our government from becoming involved in a war with Mexico ought to be appreciated by every true American citizen."

ILLINOIS

Herrin—By a vote of three to one, the miners of southern Illinois have abolished the sub-district system of government, saving the organization thousands of dollars each year in the administration of affairs of the United Mine Workers. Instead of several sub-districts, there will be 12 districts created, and each will be under a president who will handle the work that heretofore has required 10 officials.

Lincoln—After an idleness of five months the Latham coal mine recently resumed operation. This company has sufficient contracts to warrant work for several weeks. About 350 men are affected.

West Frankfort—For the fiscal year ending June 30, 1914, the mines of Franklin County produced a total of 6,569,099 tons of coal. Twenty-one fatal accidents occurred during the year or four less than the previous year. There were also 137 non-fatal accidents. The Old Ben Mining Co., of West Frankfort, worked 262 days and produced 869,982 tons without a single fatality. It appears that operators are sparing neither pains nor expense in making working conditions as safe as possible.

ARKANSAS

Fort Smith—Damages to the amount of $1,283,462.21 are asked in a suit filed in the United States District Court by Franklin Bache, receiver of the Bache-Denman Coal Co. against the national, district and local officers of the United Mine Workers of America. It is charged that the national organization indorsed the destruction of the company's property by fire and dynamite in a riot last July.

OKLAHOMA

Adamson—Eleven miners were imprisoned on Sept. 4 in the mine of the Union Coal Co., as the result of a cave-in which blocked the mines entrance. On Sept. 7, hope of ever reaching the entombed men alive was abandoned, as it was believed that it would take at least a week to remove the debris at the entrance of the wrecked mine.

COLORADO

Trinidad—Six arrests were made recently on indictments returned by the Las Animas County grand jury investigating coal strike disorders. Those arrested were William Diamond, international organizer of the United Mine Workers, three saloon men and two strikers. Th six are charged with murder on several counts growing out of the battles between strikers and mine guards during October of last year and April of 1914.

Denver—Coal land valued at half a million dollars in Jackson County reverted to the government and was lost to the Northern Colorado Coal Co., by a decree recently issued in the United States District Court. By this decree the company must pay the costs of the case and the patent to the land, bought by the company from individuals reverts to the government.

UTAH

Sunnyside—In spite of unfavorable smelter conditions, the coke plant at Sunnyside is working five days per week, and it is believed that unless something unforseen occurs, this schedule will prevail for some time to come. With improvements in the copper situation, the plant will again be put on a seven-day-a-week basis.

Recent Coal and Coke Patents

Apparatus for Regulating Combustion in Furnaces. J. F. Canady, Jersey City, N. J., 1,102,718. July 7, 1914. Filed Sept. 21, 1909. Serial No. 518,812.

Signal System for Mines. G. T. Plumb, Johannesburg, Transvaal, 1,101,951. July 7, 1914. Filed May 18, 1908. Serial No. 433,541.

Smoke Washer. L. Bottenstein, Albany, N. Y., 1,101,996. July 7, 1914. Filed Feb. 9, 1914. Serial No. 817,432.

Apparatus for Localizing the Effect of Mine Explosions. J. F. Balfour, Edinburgh, Scotland, 1,102,228. July 7, 1914. Filed July 5, 1912. Serial No. 707,795.

Superheater Boiler. J. E. Whittlesey, Pittsburgh, Penn., 1,102,836. July 14, 1914. Filed Mar. 11, 1912. Serial No. 683,136.

Steam Superheater. R. C. Stevens, assignor to Skinner Engine Co., Erie, Penn., 1,102,361. July 7, 1914. Filed Feb. 10, 1913. Serial No. 747,368.

PERSONALS

Geo. W. Evans, consulting mining engineer of Seattle, is in Montana examining coal properties.

A. H. Wood, of Petros, Tenn, president of the Petros Coal Mining Co., is organizing a company for the development of a considerable tract of coal land in Harlan County, Ky.

A H. Whiteside has recently been appointed vice-president and general sales manager of the Goulds Mfg. Co., of Seneca Falls, N. Y., manufacturers of hand, triplex and centrifugal pumps.

K. W. Rittenhouse, formerly connected with the Central West Coal Co., has taken a position as northern Ohio representative for the William J. Hamilton company, of Columbus.

Thomas J. Barr has been appointed professor of mining engineering in the College of Mines and Metallurgy, at the University of Kentucky, to succeed Prof. H. D. Easton, who recently accepted a position as instructor in the Illinois Miners' and Mechanics' Institute.

John Morris of Beckley, W. Va., is understood to be making arrangements for developing a tract of coal land on Coal River, which was recently secured by him and associates. A charter has been obtained with the object of starting the work of opening up the coal deposit.

F. P. Wright, of Bevier, Ky., was reëlected president of the Western Kentucky Coal Operators Association at the meeting held a few days ago in Louisville. Other officers reëlected at this meeting were as follows: Vice-president, C. W. Taylor, of Greenville; secretary-treasurer, B. Stewart Miller, of Owensboro.

John H. Jones, mining engineer of Wilkes-Barre, has been engaged by the Scranton School District, together with Ellsworth Davis, of Scranton, in making an investigation of conditions under the No. 40 school building. The engineers will determine which coal company is responsible for a recent disturbance of the surface, which caused damage to the school.

John J. Buttermore, president of the Catawba Coal Co. and George S. Connell have purchased the Elizabeth Mine of the Connellsville Coal & Coke Co., at Montana, W. Va. They will begin operations immediately under the name of the J. J. Buttermore Coal Co. The offices of this firm will be in Connellsville, Penn.

George Hippard, owner of the Coulterville mine and who resides at Belleville, Ill., was seriously injured when he fell from the top of the tipple at the coal mine at Coulterville, while supervising some work. He was given temporary treatment and sent to his home in Belleville, where several fractures of his arms and legs will keep him confined for sometime.

J. W. Reed, who has been an inspector at the mines of the Consolidation Coal Co., at Jenkins, Ky., for eight years, has taken the examination at the College of Mines and Metallurgy, preparatory to applying for the position of first assistant state inspector of mines. The appointment is made by the Board of Trustees of the State University, and the governor issues the certificate.

OBITUARY

Thomas E. Hughes, manager of the Philadelphia office of the Standard Underground Cable Co., died at his residence in Atlantic City recently. Mr. Hughes had long represented the Standard Co. throughout its Atlantic Coast territory from Philadelphia South, and for the past 17 years had been manager of its Eastern and Southeastern branch office sales department.

CONSTRUCTION NEWS

Chattanooga, Tenn.—It is announced that work on building the million dollar coke oven and byproduct plant of the Durham Coal & Coke Co. in Alton Park will be begun on or about Sept. 30.

Athens, Ohio—Work on repairs of the coal hoisting apparatus at Mine 209 on Sugar Creek is being pushed day and night, and it is hoped that this mine will again be ready for operation within a short time. It has been idle for several days.

Huntington, W. Va.—Another new mining town is being built on Allen's Creek in Wyoming County about four miles from Mullens, where the Wyoming Coal Co. is opening a new mine. Houses for the miners are being built and it is expected that the company will begin shipping coal within a few weeks.

Coshocton, Ohio—The Ohio Cannel Coal Co. expects to open its 5-ft. bed of coal underlying 1200 acres in Bedford Township within 30 days. The opening of the mine is in charge of S. B. Priest and George T. Heckle, who with John Orr and Simon Ashcraft own the controlling interest. The company expects to commence building tipples and installing machinery at once.

NEW INCORPORATIONS

Columbus, Ohio—Papers have been filed with the Secretary of State, changing the name of the Pomeroy Fuel Co. to the Alma-Thacker Fuel Co. The concern is located in Columbus.

Ottawa, W. Va.—The Big Eagle Mining Co. has been organized with an authorized capital of $25,000. The incorporators are J. M. Moore, James Clark, A. M. Rogers, and Edward Zwilling of Ottawa, and George S. Wallace of Huntington.

Jackson, Ohio—The Ohio & Indiana Collieries Co. has been incorporated with a capital of $150,000, to deal in coal lands and to mine and sell coal. The incorporators are E. E. Morgan, Walter McCloud, David Armstrong, Morgan J. Jones and E. E. Eubanks.

Scottsboro, Ala.—The McKenzie Coal Co. has been incorporated with a capital stock of $7500, to develop mines in Jackson County, Alabama. The officers are A. R. McKenzie, president; John D. O'Connor, vice president; J. H. McKenzie, secretary and treasurer, all of Scottsboro, Ala.

Crown, W. Va.—A charter of incorporation was recently granted to the Lowash Coal Co. of Crown, Logan Co., W. Va. This company has an authorized capital of $20,000, and the incorporators are G. I. Putnam, R. L. Carmichael, Ethel Carmichael, H. B. Summers, Mary A. Summers, of Crown, and Ida L. Putnam of Athens.

Homer City, Penn.—An application has been made for a charter for a coal mining and holding concern to be known as the Crown Hill Coal Mining Co. which will operate in central Indiana County. The incorporators are M. A. Lowther, B. M. Barker, and W. C. Lowther. This firm holds considerable coal in the Indiana field.

INDUSTRIAL NEWS

Philadelphia, Penn.—W. A. Stone & Co. have discontinued their branch office in Philadelphia.

Philadelphia, Penn.—The Italian steamship "Fert" recently cleared from this port with 7746 tons of coal destined to Italian ports.

Charlestown, W. Va.—More than 2000 claims were handled in August by the Workmen's Compensation Division of the Public Service Commission, while in one week over 525 claims were considered.

Belt, Mont.—George W. Merkle has acquired a 5-year lease upon the Anaconda Copper Mining Co.'s operation at this point, and will within the next few days place a force of men at work preparing the mine for the production of coal.

Columbus, Ohio—The Ohio Public Utilities Commission has set the time for the suspension of car-service rules on cars

loaded with fine coal to Dec. 1. The application of the Kanawha & Michigan R.R. Co., which brought the action, asked that the suspension be made permanent.

Columbus, Ohio—The Ohio Public Utilities Commission has granted the application of the Kanawha & Michigan R.R. Co. for permission to store fine coal on its lines without the usual demurrage charges. This is done in order not to flood the market with small sizes. The order will be issued in a few days.

Cincinnati, Ohio—The tow boat "Sally Marmet" struck the Government dredge boat in charge of the "Sea Lion" and sunk three barges of coal at the foot of Manchester Island on Sept. 3. The "Marmet" left for this city with the remainder of the coal. The damage in total will amount to several thousand dollars.

Washington, D. C.—Secretary of the Interior Lane receintly presided at a conference of American manufacturers of coal tar chemicals, and pharmaceutical products ,to determine whether the government can render aid in bringing about an American production of such coal tar products as hitherto have been imported.

Washington, D. C.—The third Conservation Bill that the House of Representatives has had under consideration, provides for the operation of coal, oil, gas, potassium and sodium deposits on the public land and is regarded as extremely important. The nation is rich in its natural resources but for want of adequate legislation, too many of these resources are now in a state of non-use.

Erie, Penn.—The Lake coal trade is said to be the lightest it has been this season. A number of ships that were idle the forepart of the year because they were dependent upon the coal produced in Ohio, are now busy, but those that carried coal all spring are unable to get it now in anything like operating quantities.

Connellsville, Penn.—Advices from the head of the Lakes indicate that the coal docks have a burden of about five million tons and that vessels are not getting as good despatch as a few weeks ago. The railroads are taking only small amounts of fuel, but it is expected that as soon as the grain crops start to move from the Northwest, the roads will load the cars with coal for the return trip.

Huntington, W. Va.—The Chesapeake & Ohio R.R. has received a large number of new steel coal cars, which were on order, within the past few months, and is putting them into service as fast as they arrive. This road has taken about 1300 wooden, 40-ton, flat bottom gondola cars out of service, and will put steel center sills into them at the local shops. After this, the cars will be put back in the coal trade.

Columbus, Ohio—The Ohio Public Utilities Commission has issued an order requiring the Hocking Valley Ry. Co. to operate an electric car service on the Wellston and Jackson Belt Line, connecting Jackson and Hamden. The electric service was taken off this line several weeks ago and the people along the route protested to the Utilities Commission. The company was not given the alteration of operating a steam service.

Birmingham, Ala.—Local industrial circles were recently somewhat agitated by the report that the Tennessee Coal, Iron and Railroad Co. was loading at Pensacola and Mobile cargoes of coal for the Hamburg-American line of ocean steamers. It was said that this coal was paid for in gold as soon as it was loaded. This report, however, which was thoroughly discussed and generally believed has been neither confirmed nor denied.

Connellsville, Penn.—The statement of the bituminous coal tonnage originated on the lines of the Western Maryland R.R. shows that during June, shipments amounted to 187,006 tons or a decrease of 41,796 tons as compareed with the corresponding month of the previous year. Total shipments during the first six months of 1914 were 1,363,135 tons or a decrease of 182,297 tons as compared with the corresponding period of the previous year.

Clear Creek, Utah—The Utah Fuel Co. recently made a record of 360 ft. in one month in driving an 8x12 ft. tunnel through hard rock at its Clear Creek mine. This tunnel will eventually be 4000 ft. long. Two shifts are being worked. Sixty per cent. gelatine powder is used to break the rock, the holes being on an average 6 ft. deep, 3¼-in. drills being used. New electric and other equipment will eventually be installed.

Pittsburgh, Penn.—The keen inquiry for moderate sized coal tracts convenient to railroads is taken as foreshadowing industrial revival before long. There are few buyers for large coal lands, but wherever a block of minable coal of a few hundred acres is offered for sale, it is disposed of readily at a good price. One broker, who specializes in coal lands is quoted as recently saying, that in his 12 years' experience, he never before had so many inquiries for coal properties as he has at present.

Charlestown, W. Va.—Great Britain has long enjoyed the reputation of having the best conducted and the safest coal mines in the world. A comparison of British records with those of West Virginia, however, reveal some interesting facts. In Great Britain there are 3289 mines as against 817 in West Virginia. The production per employee in 1913 was 267 tons, while in West Virginia it was 855 tons. Each person employed underground in England produced 332 tons, as against 1048 tons in West Virginia.

Newport News, Va.—A total of 1,108,539 tons of coal were dumped over Hampton Roads coal piers at Lambert's Point, Sewall's Point and Newport News during the month of August. These figures are expected to be exceeded by the September dumpings as foreign steamers awaiting cargo aggregating approximately 100,000 tons are already in port and a large fleet of others are expected to arrive to load cargoes for foreign countries which hitherto have been getting their coal supply from England and Germany.

Birmingham, Ala.—There has been no event in the Birmingham district during the past few years which has so disturbed the coal industry as the proposed increase in coal rates. It is said that the tariff of the railroads if granted by the State Commission will cost the Birmingham district 1,500,000 tons of coal per year. The production in the Birmingham district seldom exceeds 7,000,000 tons per annum, and if from that amount the railroads by proposed tariff cause to be cut off 1,500,000 tons, it will be a severe blow to the industry.

Columbus, Ohio—The Jeffrey Manufacturing Co. has issued a monthly publication, styled "Jeffrey Service," which is designed to benefit the employees of the company. W. A. Grieves, superintendent of employment and welfare, is editor-in-chief. Reporters have been named from each of the 50 departments of the huge corporation. The publication is designed "to know more about ourselves." The company has started a co-operative grocery, meat market, shoe store, bakery, dairy and restaurant for the benefit of its hundreds of employees.

Montreal, Canada—One and a quarter million tons of coal have been shipped since the opening of navigation to the St. Lawrence ports, Montreal, Quebec, Three Rivers and Levis with 35 steamers of the Dominion Coal Co. as carriers. This indicates that two million tons which are intended to be brought from Sydney during the season of navigation will be sent as the amount already arrived shows that the schedule is being lived up to. The program for September is to bring 350,000 tons of coal to the St. Lawrence ports, most of it being destined for Montreal.

Washington, D. C.—The United States Bureau of Mines is planning a comprehensive exhibit for the Panama-Pacific Exposition. The Bureau has in mind not only the value of interesting those engaged in the various mining and metallurgical industries but also the education of the general public to a better knowledge of the magnitude of these industries and to the efforts which are being honestly made by miners and mine operators toward a more safe conduct of mining and a more efficient utilization of the products of the mine after they are secured from the earth.

Newport News, Va.—Notwithstanding the embargo on credit which has proved a stumbling block in the way of South American trade since the outbreak of European hostilities, it is an interesting fact that coal shipments have been steadily proceeding during the month of August to Brazilian ports. The Booth Line during this month has sent four steamers from New York and Hampton Roads to Brazil with cargoes to Para, Manaos and Iquitos, Bahia and Pernambuco. These cargoes included 15,000 tons of coal shipped by the company from the railway terminals at Norfolk and Newport News. There is every prospect that these shipments will continue and increase.

Vivian, W. Va.—The Pittsburgh Coal Washer Co. recently closed the contract for a large modern steel tipple for the Bottom Creek Coal & Coke Co. This structure will be one of the finest ever built in the Pocahontas field. The same firm is at present building two steel tipples for the U. S. Coal & Oil Co. at Holden, W. Va., one steel tipple for the Main Island Creek Coal Co. at Logan, W. Va., one steel tipple for the Logan Coal Co. at Ethel, W. Va., two steel tipples and car hauls for the Rail & River Coal Co. at Bellaire, Ohio, one steel tipple at the Lick Branch mine of the Pocahontas Consolidated Collieries Co., at Pocahontas, Va., and several wooden tipples at various points throughout the state of West Virginia.

Coal Trade Reviews

General Review

Anthracite trade steadily improving as the season advances. Operations active and the full circular prevails. Bituminous steam trade disappointing in all parts of the country, but operators continue confident as to the future. Market well maintained. Domestic grades beginning to open up as the season advances.

The anthracite trade is steadily gaining momentum through the fall transitional period preceding the winter rush. The weather is already becoming a potent factor in the situation, some unexpectedly low temperatures having materially accelerated retail buying and created additional activity among the wholesalers. The customary slowing down at the opening of the month has disappeared and most of the companies are now well covered. Full circular prices are generally the rule and a heavy fall and winter business is in sight.

The Eastern bituminous maket is generally dissapointing though still replete with many latent possibilities. There has been a heavy increase in the foreign trade but even under the most favorable conditions this cannot attain sufficient proportions to directly affect the general market. On the other hand, the more or less complete demoralization prevailing in the world's established channels of commerce, has unmistakably crippled local industries to such an extent as to have a marked effect on the fuel consumption. But in spite of this adverse situation there are occasional reports of an incipient shortage at some points and operators are aggressively maintaining the market, confident of an active trade in the immediate future.

Indications for an early closing of Lake navigation has caused the Pittsburgh district operators to relinquish their last hopes of placing any surplus tonnages in that direction. Prices are spotty and irregular. Complications regarding credits in the Canadian trade are still puzzling producers selling in those markets. A more favorable condition prevails as regards the Lake trade in Ohio and domestic coals are also holding steady; steam grades are slowing down perceptibly and prices are under some pressure due to the tendency to reduce immediate expenditures to the minnimum.

There is considerable negotiation on foreign business in the Southern market and domestic trade is beginning to open up with the approach of the fall buying season. Some demand for steam coal is noted in the Middle Western market due, in part, to a tendency among large users to stock up before the car shortage period. The market is erratic but with a favorable undertone.

ATLANTIC SEABOARD

BOSTON

No significant change in Pocahontas and New River. Local spot demand very light, but contract shipments are well up to seasonable mark. Georges Creek loading slow because of off-shore requisitions. Pennsylvania grades continue strong. Good September in anthracite.

Bituminous—Pocahontas and New River have been marking time and there are no significant developments to report. The export trade is the chief topic of interest and apparently little attention is being paid to the market coastwise. While the volume of receipts here continues large, it is practically all contract, the local market seeming to be about as far removed from an active spot demand as heretofore. Stocks are large at all points and there is not quite the interest on the part of buyers that was predicted a few weeks ago. Many of the textile mills have closed down for a fortnight, beginning Aug. 29, and some will stay closed unless a way is found to get German dye-stuffs.

A few more steam colliers have been put back in commission and most of the agencies are moving a fair tonnage from Hampton Roads. Market cargoes are a little more easily absorbed than a month ago, but the demand for inland shipment is rather spotty and unreliable.

The Georges Creek shippers have more business just now than they can comfortably handle. The off-shore demand is strong and coastwise boats are frequently being held until clearance is given steamers for foreign ports. In some cases bottoms intended to load this grade have been diverted to Hampton Roads loading.

There is practically no change in the generally strong position of the Pennsylvania grades. All-rail there is a steady demand and consumers are beginning to urge shipments with more frequency. Most of the shippers are optimistic over the fall prospect and with Georges Creek beginning to break down on deliveries and Hampton Roads coals in line for heavy business later, it is hard to see anything unfavorable ahead, especially for the more popular grades. Prices have not changed except in scattered instances.

Anthracite—The early September demand has exceeded exceeded expectations. Orders are coming in freely. The retailers are up to their maximum for deliveries and they are likely to continue so throughout the month. A few independent offerings have been made at 5@10c. off the current circular, but as usual little tonnage was placed. Most of the companies already have about all the September orders they can handle and there is no doubt now that the market will be active for the balance of the season.

Current prices on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.90@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.15@2.80	2.00@2.90	2.92@3.02	
New York*	2.45@3.10	2.80@3.20	3.22@3.32	
Baltimore*	.....	.....	2.85@2.95	
Hampton Roads*	.....	.....	.....	$2.85@2.95
Boston†	.....	.....	.....	3.63@3.68
Providence†	.....	.....	.....	3.63@3.78

* F.o.b. †On cars.

NEW YORK

Satisfactory bookings ahead in anthracite. Insistent demand all rail and individual coals now bringing the full circular. Bituminous demand on contracts increases. Prompt market continues rather flat, though the outlook is hopeful.

Anthracite—The demand for anthracite domestic sizes for rail shipment, both East and West, continues in good volume, although not quite as strong as the latter part of August. Orders are now booked ahead for perhaps two or three weeks and with anything like a turn in the weather conditions the demand for all domestic sizes should increase. Stove continues to be the short size in all the markets. The activity in the rail markets has had a tendency of taking individual coal away from tidewater, the result being a general stiffening of prices and all sizes in the standard grades are now bringing the full circular.

The demand for pea coal for rail shipment has improved materially, but it is still inactive at tidewater. The fine sizes in the higher grades are in good demand, whereas inferior coals in the buckwheat sizes are begging.

There is a more or less general movement on the part of the retail dealers toward urging the consumer to put in his supply at once. This, in view of the increase in prices of other staple commodities due to the war is effecting the movement of retail coal and the trade generally looks for a very active and winter demand.

The market continues quotable on about the same basis as last week as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.10	$4.60@5.10	$5.05	$4.55@5.10
Egg	5.35	5.10@5.35	5.30	4.95@5.30
Stove	5.35	5.35	5.30	5.30
Chestnut	5.60	5.50@5.60	5.55	5.35@5.55
Pea	3.55	3.45@3.55	3.50	3.20@3.50
Buckwheat	2.80	2.75@2.80	2.50@2.75	2.10@2.75
Rice	2.30	2.30	2.00@2.25	1.60@2.25
Barley	1.80	1.75@1.80	1.75	1.30@1.75

Bituminous—Conditions generally seem to be improving. While the railroad-supply movement shows a falling off as compared with August, there is a notable improvement in the demand from commercial users, though the majority of the coal is moving on contract. Probably it is too early to say what effect the European war will have on general manufacturing business, and there may be no definite de-

velopments along this line for several months, but should there be a largely increased demand for goods manufactured in the United States, the coal business will be benefited.

The cooler weather should bring a larger demand, and the increased exportation of coal is a favorable factor. Reports from the mining regions indicate a more hopeful view on the part of the operators, practically all of whom report more orders for the month of September. While some coal is being offered at tidewater at low figures, the larger operators have made no change in their prices. We continue nominal quotations of last week as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.55@2.65; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

PHILADELPHIA

Situation about the same as last week although demand is not so marked, and activity in certain sizes has fallen off. Labor Day holiday causes a decrease in output. Bituminous still uncertain, but a better feeling prevails.

Anthracite—The last week of August saw a large influx of orders, with instructions to ship that month or cancel. This was particularly true of the rail business, although the Tidewater trade was also heavy. With most of these orders cleaned up, the market has eased off again, and while there is every indication that it may start up at any time, it is now the indifferent period between the summer dullness and fall activity.

The operations at the mines the past week have had their usual September set back, due to the holiday on Monday. It is understood that most of the mines commenced operations on Wednesday morning, and continued for the balance of the week. Outside of the chestnut and pea sizes, the maket still contirnues to absorb the output. Prices at Tidewater are as follows:

	Circular	Individual
Broken	$4.75	$4.75
Egg	5.00	5.00
Stove	5.00	5.00
Chestnut	5.25	4.90 @ 5.00

Bituminous—There seems to be a much better atmosphere to the bituminous situation. Consignees at Tidewater are complaining that they cannot get the coal when they want it. This applies particularly to the better grades. This undoubtedly indicates that the rail business is improving, and it is confidently expected that the end of the month will find a much better feeling all through, this branch of the trade. The outlook is promising, although there are no definite predictions as to when the improvement will occur. There is considerable tonnage moving, but the prices are not satisfactory. The demand does not seem to warrant any increase in current quotations.

BALTIMORE

Export trade continues to grow but local conditions fail to improve. Slack still farther off color. Prices generally low.

In the face of a growing export trade the domestic situation seems remarkably dull. In some cases, notably with slack, there have been sales below the quotations of last week.

At the export piers it is said that the daily shipment keeps growing. New connections are constantly being made abroad or in South America, and the coal of this country is at last a genuine competitor with the Welsh product. Charters are particularly heavy for the Argentine Republic, and many inquiries are in from that country, which is reported short of fuel.

At the mines of West Virginia, Western Maryland and Western Pennsylvania there are general reports of poor demand. The light call for industries using slack has caused that fuel to touch as low as 50c. and sales five cents off that have been recorded in some cases. Three-quarter gas is selling around 30c. at the mines in West Virginia. Pennsylvania low grade fuels are obtainable as low as 95c. to $1, and medium to best grades are offering at from $1.15 to 1.35.

HAMPTON ROADS

Shipments moving both foreign and coastwise. Inquiries still coming in for large cargoes for export. Dumpings for August amount to 1,108,539 tons.

Dumpings at tidewater for the past week have been heavy, coastwise shipments have shown up well and a large number of cargoes have moved to foreign destinations. Foreign buyers continue to look to Hampton Roads shippers for supplies and inquiries are coming in daily for large cargoes to be shipped to various South American ports; although actual sales are being made, and cargoes moved, it is difficult to ascertain at what price coal was sold. Shipments are also moving to a umber of European ports. It is understood that prices on the export coal range from $2.85 to $3, although only a small part of the coal is being sold at the latter figure.

Cargoes moving foreign during the week went to Elba, Iquique, Kingston, Canal Zone, Rio de Janeiro, Curacao, Port of Spain, Piraeus, Buenos Aires, Chaparro, Genoa, Gibraltar, Para, Cagliari, and Barbadoes. In addition, the U. S. Government has taken one large cargo to be landed at Cavitie or Olongapoo, P. I.

There is a fair accumulation of coal in the various railroad yards with shipments coming in promptly from the mines and unless there should be an exceptionally heavy demand for prompt cargoes shippers at Hampton Roads are well prepared to take care of large orders. The war conditions caused export shipments to increase greatly during August and in consequence dumpings for that month have reached well over a million tons. The dumpings over the Norfolk & Western piers at Lamberts Point amounted to 539,607 tons, from Newport News over the C. & O. Ry. piers 285,053 tons and from Sewalls Point over the Virginian Ry. 283,879 tons or a total for the three pies of 1,108,539 tons.

The Spanish Cruiser "Carlos V" is at present reparing at the U. S. Navy Yard and will take on a supply of bunker here before proceeding on her homeward voyage.

LAKE MARKETS

PITTSBURGH

Demand light all along the line and market unsatisfactory. Prices continue irregular and well below the circular figures. Mining at about 65% of capacity.

Pittsburgh district coal operators have hopes that eventually the war will improve trade, by increasing exports, at least from other districts, but thus far at any rate the influence has been in the opposite direction, exports being light and so many vessels remaining in port that consumption is reduced. The last hopes for an improvement in the Lake trade are now gone and shipments are expected to be relatively light for the remainder of the season, with an early closing of navigation at that. Manufacturing demand keeps up fairly well, but is scarcely as heavy as a fortnight ago, and the retail dealers are not yet stocking up to any extent.

Altogether the position of the coal market is quite unsatisfactory and compares unfavorably with a fortnight ago. Mine operations average about 65% of capacity. Prices continue extremely irregular, both for free coal and upon contracts. For prompt shipment slack is 50@60c. and mine-run is done at only a trifle above a dollar. Circular prices are unchanged, but purely nominal: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.50, per ton at mine, Pittsburgh district.

BUFFALO

Little life to the bituminous trade and not much indication of improvement. War influence and the financial outlook the controlling factors. Anthracite is doing better.

Bituminous—There is difference of opinion as to the state of trade, some finding the demand fairly good, while others report it as poor; the latter class doubtless predominates. One difficulty is with the Canadian trade; Canada is not paying for coal promptly and there is doubt as to the future liabilities. Some shippers are declining to sell to new customers there, on the grounds that if old connections are not satisfactory new ones are not apt to prove so. The situation is not pleasant. There is a general hesitation in every direction. The European war has hurt all branches of business and if it lasts very long there will be no money left in Europe to buy anything with; in addition, it may be many years before the old purchasing power returns.

Anthracite—There is some slacking off of trade early in the month, as usual, on account of extra buying late last month to escape the 10c. advance, but the regular fall trade is now in sight. The improvement in demand is everywhere reported. The independent anthracite dealers claim an almost full trade and at this rate there will soon be the usual fall clamoring for stove and chestnut. The Lake trade is not good for this time of the year. There is now trade enough in the West to relieve the Upper-Lake docks, so that there is room for coal there, but there is complaint that the coal is not coming forward freely, the inference being that the Eastern demand is looking up.

Anthracite shipments by Lake for the week were only 95,000 tons; for the month, 509,620 tons, and for the season, 2,728,355 tons, as against 3,308,821 tons to date last year.

TOLEDO

Domestics in fair demand and prices close to the list. Fine grades in excess supply and difficult to move. Lake shipping heavier than for some time.

The coal situation is looking brighter than for a long time past and dealers are inclined to take an optimistic view. There is a fair demand for domestic coal and prices are close to the list. A strong effort is being made to bring up the price of Hocking lump. Fine coal which formerly brought 70c. is now selling at 25c., and with but little demand. It is believed that there will be a cessation of operations shortly, unless there is an improvement in the price of fine coal.

Pocahontas can no longer be secured at circular prices and the market on lump is now $2.50. The Lake shipping is stronger than it has been for some time and more boats are moving. The coal was well cleaned up here one day last week and there was some real demand, which was, however, quickly supplied. There is as yet no congestion on the railroads. The Pittsburgh No. 8 scale committee has not yet reached a settlement.

COLUMBUS

Lake and domestic trade fairly active but steam business continues slow. The new circulars well maintained. Small sizes very weak.

The best features of the trade during the past week are the strength in the Lake and domestic departments. Both are showing a good tone and future prospects are considered bright. The steam business is slow and there is not much prospects for a betterment in the immediate future.

Fuel requirements for manufacturing are generally small as business is at a low ebb. Many factories are closed down and others are being operated with a curtailed force of men. Consequently they are not buying steam coal is as large quantities as formerly. Most of the steam contracts which have been closed are at fairly profitable figures. In the railroad-fuel business, practically all of the larger contracts are still to be let.

Lake trade is still active, although the Toledo docks of the Hocking Valley Ry. did not show up as good last week as in previous weeks. The demand from the Northwest is still good and docks at the Upper Lake ports are generally in good shape. An interior movement from the docks has started. It is predicted that there will be activity in the Lake trade up to the closing of navigaion.

Prices in the Ohio fields are:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Rescreened lump	$1.70		$1.75	
1¼ inch	1.60		1.60	$1.60
¾-inch	1.45	$1.20	1.45	1.45
Nut	1.15		1.50	1.15
Mine-run	1.20	1.05	1.15	1.15
Nut, pea and slack	0.35		0.45	0.35
Coarse slack	0.25	0.35	0.35	0.25

CLEVELAND

Retail trade brisk, but other demands are comparatively light. Markets flooded and prices have been forced lower. Lake movement light.

The coal trade is much the same as it was a week ago. The low prices at which operators have disposed of their products have forced quotations lower, but the demand has not increased. With most plants shut down last Sunday and Monday, there was no great demand over the week end. Another reason for the excess supply of coal is the meager Lake shipments. So many of the docks are not taking their usual quota of coal that operators have flooded the other markets to keep their mines going.

The condition of the market is well illustrated by the following quotations:

	Pocahontas	Youghiogheny	Bergholz	Fairmount	W. Va. No. 8
Lump	$3.85				
Lump, 6 in.			$2.50		
Egg	3.85				
Egg, 6 in.			2.10		
Lump, 1¼ in.		2.50	2.20		
Lump, ¾ in.		2.25	2.15	2.05	2.05
Mine run	2.75	2.15	1.95	1.90	1.95
Slack	2.55	1.60	1.60	1.60	1.55

CINCINNATI

Domestic and steam business dull. Labor and transportation facilities are plentiful. Some foreign demand.

The closing down of some large manufacturing plants has resulted in a worse situation locally. Other plants are running on short time, and the net result is that the steam market is slower. Small domestic consumers are waiting until an actual need for fuel arises, because of lack of money with which to buy other necessities. An optimistic view is still maintained.

Dealers are not buying to any extent just now, and the movement has been reduced to practically nothing, although there is still some coal going to the Northern and Northwestern markets by all-rail routes. There are plenty of cars offered, and men are in good supply.

COKE

CONNELLSVILLE

Coke market absolutely stagnant. Consumption promises some decrease, but production and shipments unchanged thus far. Prices not quotably changed, but probably largely nominal.

The market has been completely stagnant since last report, but this represents no material change. Four merchant furnaces, depending upon the Connellsville region for coke are just blowing out and shipments of coke have already been discontinued. One, however, will blow in late this week. Consumption by the steel interests is unchanged since they are keeping their furnaces in blast even though steel production has been slightly reduced. News has just come out of a transaction made quietly three weeks ago, a valley interest buying coke for September and October shipment to two furnaces, involving about 25,000 tons altogether, the price being $1.75. Possibly this figure could now be shaded. Market quotations are approximately as follows, though largely nominal: Prompt furnace, $1.70@1.75; contract furnace, $1.75@1.90; prompt foundry, $2.25@2.35; contract foundry, $2.35@2.50, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Aug. 29 at 25,683 tons, an increase of 18 tons, and shipments at 273,397 tons, an increase of 9284 tons. Shipments have been exceeding production for several weeks past, reducing the amount carried in stock.

BUFFALO

There is no stir in coke, as the furnaces are all running about as slow as ever, but some dealers find a slight shortage of stock coke and are quoting a few cents more. Local receipts of iron ore are good and stock piles are not unusually large. Quotations are on the basis of $4.25 for best 72-hr. Connellsville foundry and $3.30 for stock coke.

BIRMINGHAM

The coke market shows very little change over last week, but present indications are that it will shortly improve.

SOUTHERN

BIRMINGHAM

Market seems stronger than for some time. Negotiations on the South American order still under way.

While the local demand for steam coal is about the same as last week, the war has brought out heavy orders for bunker fuel at all Southern ports. One of the large operators is shipping about 1000 tons per day through the port of Pensacola for bunker purposes, and the demand at both Mobile and New Orleans has increased.

The South American business has not yet been definitely placed, due to the fact that conditions pertaining to bottoms and finances have not yet been completed; they are reported well under way, however, and it is hoped that arrangements can be completed within a short time. Some of the large operators have accepted orders subject to these arrangements being made.

Lump coal seems to be in better demand and September business promises to be much larger than August. Blacksmith coal is in a satisfactory condition with prices remaining firm. Pig iron manufacturers report many small sales with prices the same as last week.

LOUISVILLE

Trade marking time. Domestics fair but steam grades heavy. Large inquiry from Brazil.

The Kentucky trade is marking time. Prices quoted the first of the month run only to the fifteenth, and are subject to change at that time. The domestic market continues the most active, with some improvement in the industrial section of the market, though not as much as could be wished.

Prices, f.o.b. mines, are: $1.75 for block, $1.42 for 2x4 round and from 75 to 85c. for the best grades of nut and slack. Low-grade steam sizes are more or less a drug on the market.

MIDDLE WESTERN

INDIANAPOLIS

Improvement in the demand for domestic grades continues. Extra supply of screenings has caused the price to slump to 40c. Better buying of steam grades while cars are plentiful. Mines on better running schedules.

The collapse in the price of slack is the feature of the Indiana market. Two weeks ago this was in strong demand at 90c. to $1 a ton at the mines but now it is said there are offerings at less than that range, though there are also sales up to 70c. The slump is the result of the better movement of domestic grades and the consequent increase in the supply of screenings.

Good domestic coal is selling at $1.75; the best grade of mine-run at $1.20 for No. 4 and $1.10 for No. 5. There is also a slightly improved demand for steam coal, due probably to the desire of the plants to accumulate a coal pile before the season when the car shortage develops. There are plenty of cars available at present. The mines are making better time as a result of the demand for lump coal. Some of the large mines are on full time and operations over the state generally are considerably better than half-time. Retailers have made no advance in September prices yet.

CHICAGO

Steam trade light while demands for domestic coal are unusually heavy. Indiana operators also report a strong demand for domestic sizes. Prices for screenings continue to decline.

The domestic trade is unusually heavy but the steam trade is equally light. With the advent of cooler weather buying of coal for domestic purposes has taken on its customary activity and dealers report a satisfactory business.

The price for screenings has been on a decline for several weeks, 35c. a ton at the mines being a common figure. A considerable improvement has been noted in the demand for anthracite coal. The circular price on Hocking and splint has advanced 10c. a ton to $1.60. The smokeless situation remains about the same.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.22	$2.55@2.80	$2.27	
Steam lump	1.87@1.92		1.97	
Egg		2.15@2.25		$3.30@3.45
Mine run	1.87	2.55@2.80	1.87	4.05@4.30
Screenings	1.12@1.17	1.45@1.55	1.12@1.17	

Quotations for Harrisburg coal are: Domestic lump and egg, $2.55@2.80; steam lump, $2.15@2.20; mine run, $2.15@2.25; screenings, $1.45@1.55; No. 1 nut, $2.55@2.80; No. 2 nut, $2.40.

Carterville prices are: Lump and egg, $2.55@2.80; No. 1 washed, $2.80; No. 2 washed, $2.35@2.40.

ST. LOUIS

Market erratic and uncertain, but generally weak, particularly as regards the steam grades.

There is a somewhat uncertain tone to the market, occasioned principally by the fact that in the past two weeks the demand for high-grade 6-in. lump coal has exceeded the supply. This caused the market to advance to $1.75@2, as compared with $1.35@1.60 a few days previous. The high prices stopped the buying, and this sudden curtailment in the production of lump and egg was the only thing that saved the steam market from utter ruin. The result is that the past few weeks, prices for lump and egg have been a trifle unsteady, while the demand for No. 1 washed has picked up, though all the other sizes of washed coal have gone down. Screenings are also weak and are dropping.

This pertains to the coals from the Williamson and Franklin County fields. Indications are, however, that the market on these grades will continue to be good, although steam sizes may drop to a lower figure than in past years, on account of the depression in manufacturing circles.

	Williamson and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	....	....	$1.05	$0.90@1.00	$0.90@1.00
3-in. lump	....	....	1.30	....	....

KANSAS CITY

Retail trade slightly better. Prices did not advance as usual on Sept. 1. Situation unsettled.

Cooler weather was a factor in larger retail trade. Prices did not advance Sept. 1; there was a general feeling, however, that the advance will occur Sept. 15. It is very generally expected among Kansas City wholesalers that prices will be raised 25c. a month during the interval between the middle of September and December, and some say this will continue to February.

Steam and slack coal are irregular; high-grade Missouri block coal is ten cents higher at $2.10. There has been a good market here for Illinois coal. The settlement of the strike in the Kansas field promises more liberal and steady supplies.

PORTLAND

Supplies light and regular circular has been advanced. Some mines closed down.

Utah and Wyoming coals advanced 50c. Sept. 1 and are now selling at $10 for lump and $9.50 egg, retail, with no reduction on larger than three-ton lots. Dealers say that the supply on hand is exceedingly light and that the advance is fully justified by conditions.

Some of the mines are shut down, among them being the big Carbon Hill mine and the MacKay and Hyde mines.

No coal is reported coming here from Australia this season and whether any will come from the Atlantic Coast by way of the Panama Canal has not been ascertained yet.

FOREIGN MARKETS

ENGLAND

Prices irregular and production heavily restricted. High water freights and heavy war insurance charges complicate the situation.

The London coal trade is moving very quietly this week. Best coals maintain their prices, but all second qualtities are difficult to sell. Fortunately the supplies are limited through the dislocation of the railway traffic and short time at the collieries, or the depots would become congested. Prices are very irregular. The shipping trade is weak.

Now that the bond and embargo on the exportation of coal have disappeared, the coal trade at the exporting centers is gradually recovering from the stagnant position in which it has remained since the outbreak of the war. There are still many difficulties, however, which continue to restrict trade, and among these those of high freight and war insurance risks rates and of finance may be mentioned as the more important.

On the whole the demand has been healthier during the past week, and altogether the outlook has improved. Although the Wear market is still greatly disturbed, the situation is more promising. At Cardiff the withdrawal of the triple bond has served as a great stimulant to the outward market, though the home demand has fallen off somewhat. In the Midlands business is quiet, especially in Lancashire.

A deputation of trade unions laid certain proposals before the Prime Minister for alleviating the financial effect of the war upon unions.

A special conference of the South Wales Miners' Federation is to be held to consider means for alleviating the distress caused by the restriction of employment at some of the collieries.—"The Colliery Guardian."

ITALY

There are no manufacturers of importance at Brindisi, and the coal imported from the United Kingdom and United States is mainly used for bunkering, the manufacture of patent fuel, and by the railway. In 1913, 153,884 tons of coal were imported. At Bari 105,398 tons were imported, at Barletta 52,079 tons, and at Taranto 70,653 tons.

According to the Corrier d'Italia, a report on the quantities of coal existing in the harbours of Genoa, Savona, Naples, and other important stations on the Italian seaboard, was demanded by the Council of Ministers on Thursday last, and the next day Commissioners commenced an inspection, with a view to giving the required information. The British coal export trade having been seriously injured by the outbreak of hostilities, especially as large quantities of British coal used to be taken by Germany, it is suggested that the moment is now a propitious one for arranging a considerable export of coal to Italy. The managing board of the Italian State Railways is, our contemporary learns, prepared to place very large orders for coal in Great Britain, as well as in America. —"The Colliery Guardian."

COAL AGE

Vol. 6 NEW YORK, SEPTEMBER 19, 1914 No. 12

There are mines in almost every coal field of the United States where the men are working a seam that carries bands of impurities which must be separated from the coal to make it marketable.

In any given district, these bands of impurities are fairly uniform in number as well as in thickness and composition, but in comparing different fields, every conceivable variation is encountered. Often the question of whether a certain seam of coal can be worked profitably, hinges entirely on the possibility and cost of eliminating the slate and bone.

There are three possible methods for handling such impurities—1. Separating the refuse and the coal inside the mine while loading the mine cars. 2. Loading the entire seam just as it comes (coal and bands of impurities), and then depending on mechanical means such as washeries and picking belts to eliminate the waste rock at the tipple. 3. A combination of 1 and 2.

The last method is the one generally adopted.

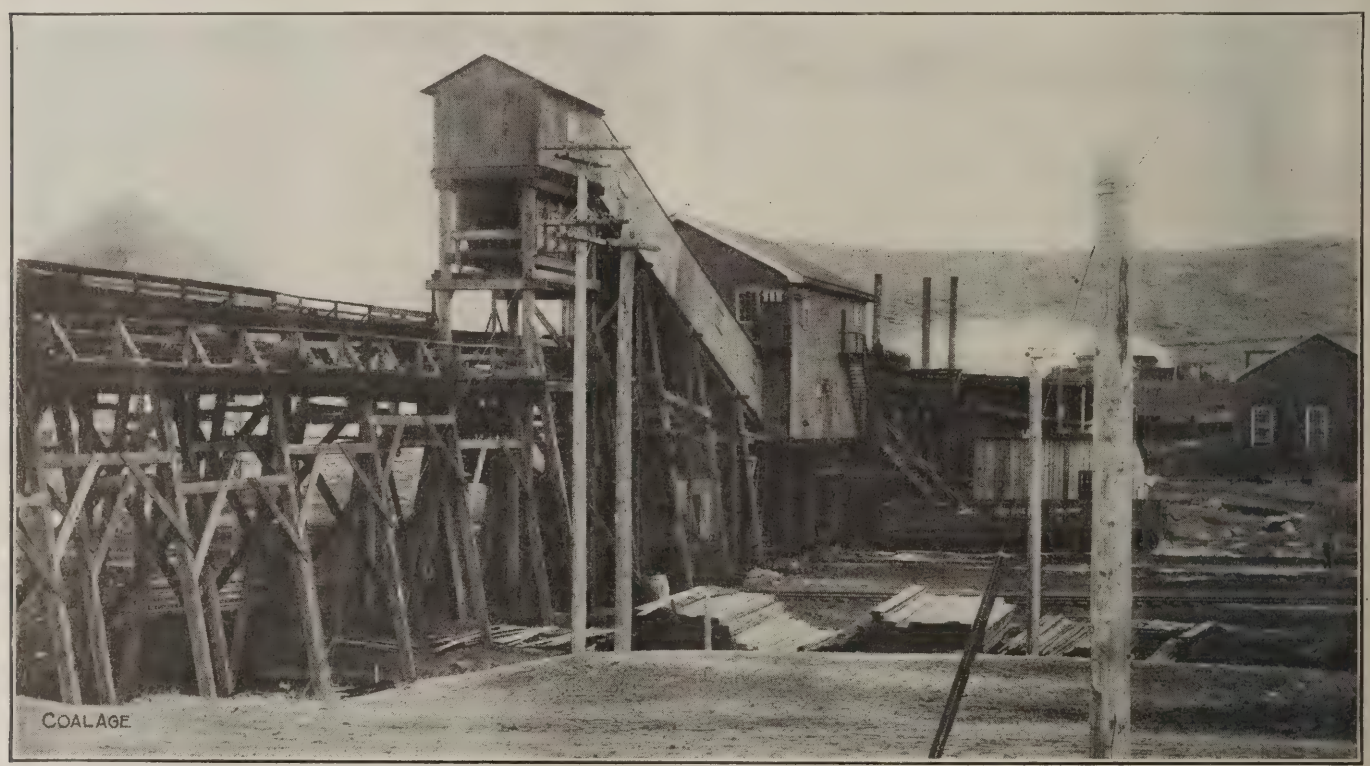
At all mines where either the first or last plan is in vogue, some system of inspection has to be employed to check the work of the loaders. In connection with such inspection a system of dockage is enforced to punish all offenders who load more than the maximum allowable quantity of refuse, and in extreme cases the guilty ones are discharged. Just now with miners plentiful and orders scarce the "slate bosses" are rarely questioned when they turn in discharges.

In many camps the earnings of the miners as well as the dividends of the operating company are largely dependent on the method of enforcing the dockage system. For example, if the character of the coal seam is such that the miners can just make a living at best, they are liable to take chances occasionally and load more rock than they should, hoping that the inspector won't happen to pick the outlawed car. As a result when the miner does get caught, he is either fined so heavily that his earnings for the month are reduced below the possible living minimum or he is discharged.

The operating company is also a heavy loser, because the average quantity of impurities in the "mine-run" is increased and the constant changing of miners is costly.

Much of this trouble can be eliminated by employing inspectors to watch the loading of the coal at the working face. These inspectors give the miners to understand that the company does not want to dock them and should have no need for docking them; they instruct the miners as to the best method of shooting and loading the coal and whenever necessary load a part of a car just to show the worker that it can be done. Four or five inspectors can cover a pretty large mine if they are conscientious and manage to visit every working place several times each week.

The miner is thus made to realize that he can earn just as much by following instructions as he could under any other plan, and he can save the energy formerly wasted in topping cars of dirty coal, besides he can keep a clear conscience and relieve his family of the constant fear of his discharge.



A clear conscience is a pretty good taskmaster; help the miner to keep it awake.

The Electrification of the Cottonwood Coal Co.'s Mines

By Cornelius Webber*

SYNOPSIS—A thorough investigation of conditions led to the belief that electric operation would be cheaper than steam. Records kept after electrification was completed verified the soundness of this conclusion.

After a thorough investigation covering operating expenses and the various advantages to be gained by changing from steam to electrical operation, the Cottonwood Coal Co., of Stockett, Mont., installed the latter system and commenced operation with the new equipment in November, 1912.

General View of a Tipple

At the time the electrification was completed the company was operating three mines, Nos. 5, 6 and 7.

Number 5 mine is located about one mile northwest of Stockett, No. 6 mine about two miles southeast and No. 7 mine about 4½ miles northwest.

Originally these three mines were operated by steam driven air-compressor plants, Nos. 5 and 6 mines having been operated from an installation common to both. The latter plant, as well as the haulage and crusher equipment, was located in the town and between the mines.

No. 7 mine was provided with a separate steam-driven compressed-air plant and the coal was loaded from a separate tipple.

Compressed-air coal punchers, drills, pumps and hoisting engines were used in all mines, a steam-driven rope-haulage system transported the coal from Nos. 5 and 6 mines and separate steam-driven ventilating fans supplied fresh air. The crusher plant, slack-coal conveyor, box-car loader, rock hoist, sawmill and machine shop were all operated by steam engines.

The comparatively low cost of electrical energy and the elimination of many high-priced men were in a great measure responsible for the electrification. The old air compressor plant, at Stockett, was abandoned, and a new motor-driven plant provided. The steam haulage machinery was retained, while motors were substituted for steam engines in the crusher plant, box-car loader, sawmill and slack-coal conveyor. Electric lines were extended to mines Nos. 5 and 6, for operating the old steam-driven fans and motors.

With the present arrangement 3-phase 60-cycle current is purchased from the Great Falls Power Co., and enters the substation in Stockett at 50,000 volts. After passing through suitable high-tension switching apparatus it is stepped down by means of three 1200-kv.-a. water-cooled transformers to 2200 volts.

Two 500-hp., 2200-volt, 3-phase, 450-r.p.m. induction motors with external starting resistance and two belt-driven Ladlow-Dunn-Gordon, two-stage, 24x29-in. (low-pressure cylinder) 110-r.p.m. air compressors are installed in the same building, the pipe line being connected to the old air mains.

One 2200-volt, 3-phase line runs to No. 5 mine and another to No. 6. At each of these two plants the current is stepped down to 220 volts. A 35-hp. induction motor at No. 6, and one 35-hp. and one 10-hp. induction motor at No. 5 mine operate the ventilating fans.

*Electrical engineer, Cottonwood Coal Co., Stockett, Mont.

The current is also stepped down for operating the sawmill the slack-coal conveyor, a 30-hp. motor and for the company lights.

The crusher plant is located near the No. 5 mine 2200-volt line, which is tapped to supply a 75-hp., 2200-volt induction motor and a 2200- to 440-volt, 3-phase transformer, which supplies a 50-hp. box-car loader and a 10-hp. rock conveyor motor. A 2200-volt primary lighting distributing circuit supplies the town.

At No. 7 mine the steam-driven compressed-air and ventilating plants were entirely abandoned and electrical coal-punching machines, drills, pumps, fan and hoist motor, together with an electric-locomotive haulage system were installed.

The current comes in at 2200 volts, 3-phase from a substation at Sand Coulee, one and one-half miles away, and operates a 200-hp. induction motor, direct-connected to a 125-kw., 250-volt, direct current generator, which supplies the electric locomotive.

A branch 2200-volt circuit feeds two 50-kv.-a., 3-phase, 2200- to 440-volt transformers, the latter supplying a 35-hp. fan motor, a 35-hp. hoist motor, a 7½-hp. and a 10-hp. pump motor, besides two 5-hp. drills and six 7½-hp. coal punchers.

Lighting service is furnished by a separate transformer at 110 volts secondary, and a forge blower in the blacksmith shop operates from the same mains.

Meters have been installed at various points and accurate account was kept of the operation. The figures below show the average consumption of current per month during the first year and a comparison between direct application of electrical power and indirect application through electrically operated air compressors.

NUMBERS 5 AND 6 MINES

Average number of working days per month..... 20

Average Kilowatt-Hour Consumption of Electrical Energy, per Month

Compressors	Crusher Plant	Mine No. 5 Fan	Mine No. 6 Fan	Slack Coal Conveyor	Lighting
228,000	3750	8970	4500	820	1650

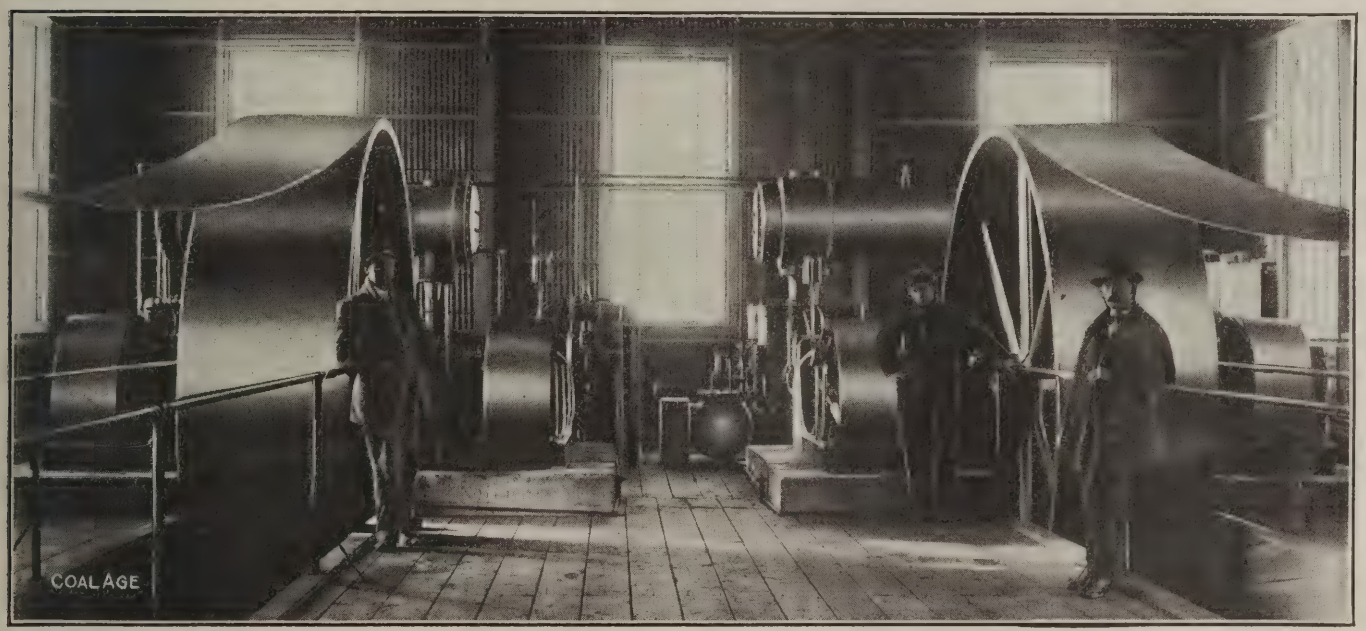
Total, 247,690.

Average tonnage produced per month..... 30,300

Average Kilowatt-Hour Consumption per Ton Produced

Compressed Air	Crushing	Ventilation	Miscellaneous	Total
7.52	0.123	0.444	0.08	8.168

Average number of pounds of coal consumed per ton produced previous to electrification.....	114.4
Average number of pounds of coal consumed per ton produced after electrification.....	27.2
Percentage cost of power-plant labor after electrification to cost of same item before electrification..	60.6



No. 7 Mine (Month of August, 1913)

Number of tons of coal produced.....	4,444.3
Number of kilowatt-hours consumed, mining machines, drills, pumps and electric hoist combined..	3,290
Ventilating fan.....	1,675
Haulage system.....	5,725
Total	10,680

Kilowatt-Hours Consumed per Ton Produced

Mining machines, drills, pumps and hoist.....	0.718
Ventilation	0.377
Haulage	1.29
Total	2.385

It is apparent that direct application of electrical power at the machines brings about great economy of current consumption. Furthermore, the plant at No. 7 mine requires no station operator, the motormen and blacksmith being selected to oil and operate the apparatus.

COMPRESSOR ROOM, SHOWING THE TWO BELT-DRIVEN UNITS

No. 7 mine produces coal on a much smaller scale than either No. 5 or No. 6, and has the consumption of current for haulage taken into consideration, whereas Nos. 5 and 6 require extra coal and the services of haulage engineers.

It seems, however, that the average machine man cuts less coal per day with an electric puncher than with an air puncher, owing to the fact that the former has only one speed of operation. The economy of energy, however, offsets this loss unless current sells at an extremely low price.

The electric drills in use at present give little trouble, but are rather heavy for fast work. A good electric drill that would penetrate sulphur balls without breaking the steel and that would not exceed an air drill in weight would be a boon to the coal miner and operator in places where sulphur balls are encountered and would greatly facilitate electric mining.

Development of the Jenkins-McRoberts District of Kentucky

By W. B. Webb*

SYNOPSIS—In spite of many obstacles in the way of transportation facilities, Jenkins and McRoberts in the Elkhorn field of Kentucky have risen from a wilderness to thriving and prosperous communities in less than three years.

One of the largest coal mining plants in this country is that of the Consolidation Coal Co. in the Elkhorn field of eastern Kentucky. Three years ago, eastern Kentucky, particularly the Elkhorn field was practically unknown. About that time the above mentioned company purchased approximately 100,000 acres lying largely in Letcher County along the tributaries of the Kentucky and Big Sandy Rivers.

The Surface Plant at No. 201 Mine

Development work was immediately undertaken in and about Jenkins. The nearest railroad upon one side was 100 miles away, and on the other, about 35 miles with rough country lying between. The Lexington and Eastern R.R. owned by the Louisville & Nashville system built an extension from Jackson south into the head waters of the North Fork of the Kentucky River, approximately 103 miles in length. On the other side the Chesapeake & Ohio constructed a branch along the Big Sandy River. The Baltimore & Ohio also constructed a branch road from Shelby Station, in Pike County, a distance of about 32 miles.

As soon as the railroad construction was well under way the building of McRoberts, which was to be its terminus, was commenced. Mills were installed in the forest, in which was manufactured the lumber necessary for the building of the miners' houses and other structures. A brick plant was also established, likewise a power plant of 10,000-kw. capacity. This latter supplies McRoberts, Dunham, Burdine and other nearby mining towns, besides half a dozen or more substations. This plant is now said to be the largest south of Mason's and Dixon's line.

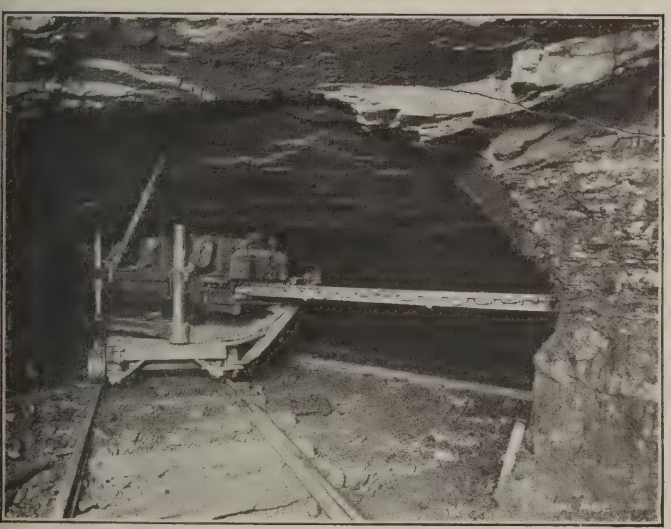
This power plant furnishes power to the Elkhorn Mining Corporation, the Elkhorn Fuel Co., the Milwaukee Gas & Coal Co., and the Beaver Creek Coal Co., at Weeksbury and Wayland, some 30 miles distant, while lines are now being built into Van Lear, almost 70 miles away.

All the new towns of this company, including Jenkins, McRoberts, Durham and Burdine were remarkably rapid in their growth, especially when one considers the rough topography of the country, and the poor roadways over which it was necessary to haul much of the material and equipment. Thus practically all of the machinery entering into the power plant had to be transported over the mountains by wagon.

Only a portion of the acreage of the Consolidation Coal Co. is being developed by that firm itself, the balance being subleased to other operators. This company also has plants in the Somerset section of Pennsylvania, the Fairmount region of West Virginia, the George's Creek big vein region of Maryland, and some extensive operations in the Miller's Creek section of Johnson County, Kentucky.

The Nicola Building Co., of Pittsburgh, Penn., built Jenkins and the other towns for this firm on contract, putting up 1600 houses in Jenkins alone, all of which were modern structures plastered inside. There were also many other buildings, houses, offices, stores, Y. M. C. A.'s, churches, school buildings, etc. There were also a bakery, ice plant and other structures, costing all the way from $25,000 to $70,000 each to be built, all of which work, as well as road building, was carried on by the Nicola company, with promptness and dispatch.

One of the principal ideas kept in mind by the Consolidation company in the development of this property



*Sergent, Ky.

Tipple for Mines Nos. 207 and 208

Power Plant of 10,000-Kw. Capacity at Jenkins

Type of Mining Machine Used

was the interests of its employees. Almost as soon as any work was started at all, a Y. M. C. A. headquarters was established. This temporary beginning was later enlarged and finally a creditable permanent Y. M. C. A has been built. The mines of this section begin at No. 201 and go to 207. No. 201 is located at Burdine, 202 is between that point and Jenkins, while Nos. 203, 204 and 205 are located at the latter point. Nos. 206 and 207 are at Dunham, on the headwaters of Elkhorn Creek.

At McRoberts, the mines are Nos. 211, 212, 213, 214 and 215, while the same coal bed is worked as that at Jenkins. This seam is about 12 ft. thick, with thin slate partings. The roof is said to be perfectly safe, and thus far there have been no fatalities from falling slate.

At the present time, coal orders are coming in at an unusual rate, and increases in operating force are contemplated. At present about 160 cars, or approximately 7000 tons are mined per day. By the end of the year it is hoped that this amount may be doubled. This is believed quite possible, depending only on market conditions.

There are now something over 2000 men employed at the mines in Jenkins and McRoberts, exclusive of the office force, which comprises about 100 men and which will, of course, be increased as mining progresses.

Jenkins today has a telegraph and telephone system, electric lights, water-works, a national bank, a bakery, dairy, ice plant, a weekly newspaper, a city hospital, supply and machine shops, schools, churches, Y. M. C. A.;

A Street in Jenkins

The Jenkins Post Office, Y. M. C. A. and Drug Store

in fact, almost everything which goes to make up a live, wide-awake city. Miners and others coming to Jenkins can educate their children as easily as they can in the large cities, since there is a large central school in a $30,000 building and five division schools, all supplied with competent teachers.

Rents in both Jenkins and McRoberts are reasonably low, and every inducement is given to tenants to save money for the proverbial rainy day. Hundreds of men are taking advantage of this, but there is here, as elsewhere, a shiftless, happy-go-lucky class, such as often frequents mining towns. These people are constantly on the move and do little good anywhere. It is believed, however, that there are inducements here that cannot be found in any other mining community in the country.

We are indebted to William J. Flaherty, who kindly assisted in securing the photographs here presented, as well as the descriptive matter. Mr. Flaherty, who is one of the congenial office men, came to Jenkins when the first developments were started, and has consequently had an opportunity of seeing the town grow from a wilderness to its present status.

Texas Breaks Coal Records

The State of Texas mined in 1913, 2,429,144 short tons of coal, valued at $4,288,920, according to E. W. Parker, of the U. S. Geological Survey. This production was almost evenly divided between lignite and bituminous coal, with the balance slightly in favor of the latter.

Both classes of fuel showed increases in production, and both made their record output. The total production in 1913 exceeded that of the previous year by 240,532 short tons, or 11 per cent. in quantity, and by $633,176 or 17 per cent. in value. Most of the increase in tonnage was derived from the lignite mines, whose output showed a gain of 190,451 tons, the production of bituminous coal increasing 7081 tons. In point of value, however, the advantage was as much in favor of the bituminous coal as the gain in quantity favored the lignite. The value of lignite increased $123,971, while that of the bituminous product increased $409,205.

The coal beds of Texas belong to three distinct geologic systems—the Carboniferous, Cretaceous and Tertiary. The Carboniferous coals are found in the north-central part of the state, the principal mining operations being in Eastland, Palo Pinto, Erath, Wise and Young Counties. The Cretaceous coals occur near the southern part of the state, and are mined chiefly near Eagle Pass, in Maverick County. The coals of this district which extends into New Mexico and are mined extensively at El Fenix near Sabinas and at Esperanvas, are classed as bituminous coals, and in the southern portion of New Mexico make a fair grade of coke.

The lignite beds are of enormous extent and occur in a wide belt, which stretches from the Sabine on the north-east of the Rio Grande in the southwest. Like the Cretaceous coals these seem to improve in quality to the southwest, and near Laredo, in Webb County, the lignite is changed to a higher-grade coal approaching cannel in character and classified as bituminous. The principal lignite operations have been carried on in Anderson, Bastrop, Fayette, Henderson, Hopkins, Houston, Lee, Leon, Medina, Milan, Rains, Robertson, Shelby, Titus, Van Zandt and Wood Counties.

The development of the lignite resources of Texas began in the closing decade of the 19th Century and except for a temporary setback in 1902 and 1903, after the discovery of petroleum, has progressed steadily with the development and growth in population. Lignite is found to be an excellent fuel for the gas producer and the vast resources of Texas in this regard possess great potentialities for the future.

The first record of the production of bituminous coal in Texas is contained in the volume of mineral resources of the United States in 1884, which states that the quantity mined in that year was 125,000 tons. The total production of lignite and bituminous coal in 1913 was about 20 times the output of 1884.

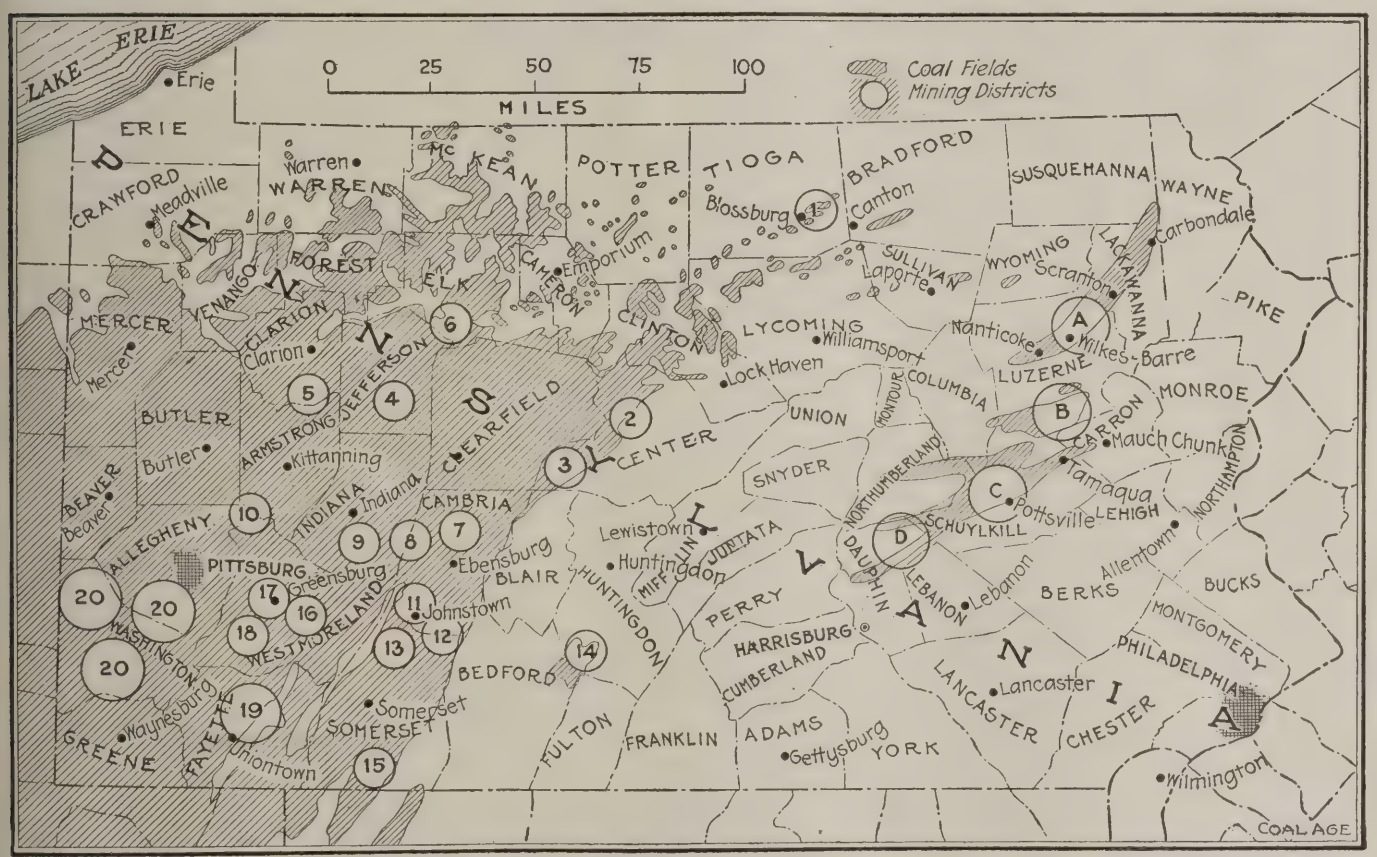
Government Aids Coal Exporters

With a view to aiding the coal operators of the United States to expand their markets at a time when the exporters of other coal-producing nations are inactive, the Bureau of Mines has issued a bulletin describing the various coals of the country which are best available for foreign shipment. The bulletin, which is printed in Spanish, Portuguese and English, will be given special distribution among the large coal users and importers of South and Central America. That this important field is as yet slightly developed as a market for United States coals is shown by the statistics of coal exports. Of 16,083,101 tons of coal exported during 1913, but 450,000 tons went to South America. Canada was the best customer, taking 11,500,000 tons.

The bulletin lists as available for this promising export trade seven groups of coal fields. These are the Pocahontas and New River coals of West Virginia, with Norfolk and Newport News as shipping ports; the Maryland and eastern Pennsylvania coals, to go through Baltimore or Philadelphia; the Virginia, Kentucky and Tennessee coals, through Hampton Roads or Charleston; the Alabama coals, through Mobile or New Orleans; the western Pennsylvania coals, through New Orleans; the Illinois and Indiana coals, through New Orleans; and the Washington coals, through Seattle. The bulletin gives in detail the general characteristics of the various coals, and points out which are the best adapted to railroad use, manufacturing, gas-making or coke-making. Average analyses are given, and the heating values are expressed in British thermal units and in calories.

"Coals of excellent physical character and of high heating value are available for export," states the bulletin. "For this reason and because of the modern facilities at the collieries for properly grading large shipments, the American producers can export coals suitable for any kind of service. The transportation systems from the mines to tidewater and the coal-handling equipment for loading boats at the various ports are highly developed so that producers are able to give excellent service to foreign buyers. Enormous quantities of these coals have been used by railroads, manufacturing plants and seagoing vessels, and for household purposes. Much of the coal available for export is superior to that heretofore supplied to foreign users from other

Geology and Location of the Coal Fields of Pennsylvania



By J. S. Burrows*

SYNOPSIS—A geological classification of all the Pennsylvania coals with comments on their commercial importance. Also map showing location of the different fields. The uses to which the various coals are generally confined together with the railroads draining the districts are noted.

The accompanying tables and map covering the bituminous coal fields of Pennsylvania have been compiled with the object of providing, for convenient reference, a key to the coals of that state. While all of the best authorities have been consulted in preparing these data, the tables have been purposely limited in scope to the essential facts relative to the correlation, location and commercial importance of the coal beds.

Pennsylvania was the first state to have a systematic gelogical survey of its coal fields, the data obtained in the original survey having been augmented by later investigations of both the state and national government; as a result the distribution and correlation of the coals are considered to be accurately determined.

*Fuel expert, Castner, Curran & Bullitt, Inc., Norfolk, Va.

Coal Areas of Pennsylvania and Location of the Different Districts

MAP NO.	NAME OF DISTRICT	RAILROADS	BITUMINOUS DISTRICTS KIND OF COAL	PRINCIPAL USES OF COAL	Index Nos. Important coal beds
1	Blossburg	Erie-NYCRR	Semi-bituminous (c) (low volatile)	Smithing	3-4-6
2	Snowshoe	PRR	Semi-bituminous (low volatile)	Smithing and steam	6-8-9
3	Clearfield	PRR-NYCRR	Semi-bituminous (low volatile)	Steam, bunker, railway and coke	6-8-9
4	Reynoldsville	BR&PRR-PRR	Bituminous (d) (medium volatile)	Steam and railway	6-9
5	Low Grade Division	PRR	Bituminous and cannel (c) (high volatile)	Steam, railway and domestic	6-8-9
6	Shawmut	PS&N	Bituminous (high volatile)	Railway, steam and domestic	5-6-9-10
7	Cambria	PRR NYCRR	Semi-bituminous (low volatile)	Steam, bunker and coke	6-8-9-10
8	Two Lick	PRR (a)	Semi-bituminous (low volatile)	Steam, bunker and coke	6-8-9-10
9	Indiana	PRR	Bituminous (high and medium volatile)	Coke and steam	6-8-9-10
10	Alleghany River	PRR	Bituminous (high volatile)	Steam and domestic	6-8-9-10
11	Johnstown	PRR	Semi-bituminous (low volatile)	Steam and coke	6-8-9-10
12	Southfork Windber	PRR	Semi-bituminous (low volatile)	Bunker and steam	6-8-9-10
13	Quemahoning	B&ORR	Semi-bituminous (low volatile)	Steam	6-8
14	Broadtop	PRR (b)	Semi-bituminous (low volatile)	Steam and coke	3-4-6-10-11
15	Meyersdale	B&ORR	Semi-bituminous (low volatile)	Steam	10-13½-14-16
16	Latrobe	PRR	Bituminous (high volatile)	Coke, steam and railway	16
17	Greensburg	PRR	Bituminous (high volatile)	Coke, steam and railway	16
18	Youghiogheny	PRR	Bituminous (high volatile)	Illuminating gas, coke and steam	16
19	Connellsville	PRR-B&ORR	Bituminous (high volatile)	Coke	16
20	Pittsburgh	PRR&B&ORR	Bituminous (high volatile)	Steam, railway, coke and domestic	16-18

ANTHRACITE REGIONS

A. Wyoming B. Lehigh C. Schuylkill D. Lykens Valley

Notes—(a) Cherrytree and Dixonville Ry. (b) Huntington & Broadtop RR. (c) Low volatile—12 to 22% volatile matter. (d) Medium volatile—22% to 30% volatile matter. (e) High volatile—over 30% volatile matter.

The Bituminous Coals of Pennsylvania

Index Number	Series	FORMATIONS	NAMES OF COAL BEDS	LOCAL NAMES OF COALS	COMMERCIAL IMPORTANCE
26	Permian (Dunkard)	Greene	Ninevah		Commercially unimportant.
25			Dunkard		Commercially unimportant.
24	(Upper) Carboniferous System	(Upper Barren) XVI	Jollytown		Commercially unimportant.
23		Washington	Washington		Mined to some extent in Washington and Greene Counties.
22			Waynesburg B.		Commercially unimportant.
21			Waynesburg A.		Commercially unimportant.
20	Pennsylvanian	(Upper Productive) XV	Waynesburg		Best development in portions of Greene, Washington and Westmoreland Counties where it is mined for local use.
19		Monongahela	Uniontown		Important only in Fayette and Washington Counties and not extensively mined.
18			Sewickley	(Mapletown in Washington and Greene Counties)	Best development along Monongahela River in Greene County where it is extensively mined and used locally as a high grade domestic fuel.
17			Redstone		Of little value and probably affected by extraction of underlying Pittsburgh coal.
16			Pittsburgh		The most uniform in quality and thickness and, for a given area, the most valuable coal bed in the bituminous coal field of Pennsylvania. It is estimated that this bed originally contained more than ten billion tons of available coal. The main body of the coal lies in the southwestern corner of the state, embracing the whole of Greene and Washington Counties, and extending east into Fayette County and north into Allegheny County. There are several large areas in Westmoreland County and isolated patches in Somerset and Indiana Counties. The Pittsburgh coal is the source of the famous Connellsville coke and the Youghiogheny gas coal. It is extensively mined except in the center of the Greene-Washington County area where the bed lies deep below the surface. More than half of the coal produced in the state comes from this bed.
		(Lower Barren) XIV		(Painter in Westmoreland County)	A variable unpersistent bed occurring in the top of this formation, and mined locally in Westmoreland County.
15		Conemaugh	Little Pittsburgh		A commercially unimportant thin bed having a wide extent in Greene, Washington, Fayette, Westmoreland and Somerset Counties.
14			Elk Lick		A commercially unimportant variable bed of workable thickness in Somerset County and formerly mined in Fayette and Westmoreland Counties.
13½				(Berlin in Somerset County)	Although this coal has not been correlated with any of the well known coals, it is the most valuable bed of the Berlin district in Somerset County where it is extensively mined for shipment.
13			Bakerstown	(Price in Somerset County)	Mined to some extent in Allegheny County and correlated with the Price coal of the Berlin district in Somerset County where it underlies a large area, and is one of the most important coals.
				(Coleman in Somerset County)	Furnishes a small amount of coal in the Berlin district of Somerset County.
				(Philson in Somerset County)	This bed which has not been correlated is mined to some extent in the Berlin district of Somerset County.
12			Masontown		Commercially unimportant.
11			Gallitzin (*Mahoning*)	(Spear in Bedford and Huntingdon Counties) (Brush Creek and Millerstown in Butler County) (Brush Creek in Lawrence County)	Commercially unimportant except in Broadtop field of Huntingdon and Bedford Counties.
10		(Lower Productive) XIII	Upper Freeport	(E) (Lemon and Cokeyard in Cambria County) (Kelly in Bedford County) (Sawmill along Pa.-Md. line) (Represented in Beaver County by 4-foot and 5-foot beds) (Cap seam in Clearfield County) (Connellsville in Greene County)	One of the most important coals and source of great production. Extensively mined as the Kelly bed in Bedford County. Principal source of coal along Kiskiminitas River in Armstrong County. Most important coal in Indiana County, and next to the Lower Kittanning bed, the most valuable coal in Cambria County. Extensively mined in Westmoreland County, and has a large area and is mined to some extent in Somerset County. The important coal mined as the E seam in Lycoming County is regarded as belonging to this horizon.
9		Allegheny	Lower Freeport	(D) (Moshannon in Clearfield and Center Counties) (Limestone in Southern Cambria County) (Schantz and No. 5 in Butler County)	Chief coal of Clearfield County and the source of an enormous output in the following districts: Reynoldsville, embracing portions of Jefferson, Indiana, Clearfield and Elk Counties; Phillipsburg-Houtzdale, embracing portions of Clearfield and Center Counties, Punxsutawney, of Jefferson and Indiana Counties; and the Patton-Barnesboro district of Cambria County.
8			Upper Kittanning	(C′) (Darlington and North Washington cannel in Beaver County) (Woodland cannel in Clearfield County) (Middle or Big bed in Center County) (Cement in southern Cambria County) (Cement or Rock vein in Somerset County) (No. 4 and creek vein in Butler County)	One of the important sources of coal and the horizon of the Pennsylvania cannel coals. Principal coal, as the Big bed, of the Snowshoe district in Center County. It is one of the principal coals of Somerset County, extensively mined about Johnstown in Cambria County, and is largely workable throughout Butler County.
			Gorman		Commercially unimportant.
7			Middle Kittanning	(C) (Twin seam-?-in Bedford and Huntingdon Counties)	Generally too thin and dirty for mining, though worked at a number of points for local use. It is found in its best condition and development in the northern and eastern portions of the main field.
6			Lower Kittanning	(B) (Miller or Sonman in Cambria County) (Dagus or Daguscahonda in Elk County) (Bloss- -in Tioga County) (Barnet in Bedford and Huntingdon Counties)	Next to the Pittsburgh bed this coal is the most persistent, uniform and reliable bed in the bituminous field of Pennsylvania. The zone within which it lies includes nearly one-half the entire area of the main coal field. It is exposed in workable thickness in Armstrong, Jefferson, Indiana, Clarion, Center, Clearfield, Cambria, Blair, Somerset, Fayette and Elk Counties. The principal mining operations are in Center, Cambria and Somerset Counties. As the Barnet bed of Bedford and Huntingdon counties, it is the most important coal of the Broadtop field.
5			Clarion	(A′) (Pardoe-?- in Mercer and Butler Counties) (Clermont-?-in Elk, Forest and McKean Counties (Scrubgrass in Clarion, Venango and northern Butler Counties).	Of little commercial importance except in the vicinity of Clermont in McKean County.
4			Brookville	(A) (Pardoe-?-in Mercer and Butler Counties) (Clermont-?-in Elk, Forest and McKean Counties) (Cook or Fulton in Huntingdon and Bedford Counties) (Cushman or Seymour in Tioga County)	Of little commercial importance but mined to some extent along eastern margin of main coal field and in the Broadtop field of Huntingdon and Bedford Counties. It is of workable thickness in Jefferson, Clearfield, Center, Cambria and Somerset Counties.
3		(Seral Conglomerate) XII	Mercer Group	(Upper and Lower Mercer) (Upper Middle and Lower Alton in McKean County) (Mt. Savage along Pa.-Md. line) (Gaines in Potter County) (Bloss in Tioga County) (B-?-in Lycoming and Bradford Counties) (Bear Run in Blossburg basin) (A′-?-in Bernice basin)	Generally lacking in persistence, but locally important group of coals, and the principal source of fuel in McKean County where the Upper, Middle and Lower Alton beds are extensively mined. The most important coals of Potter, Lycoming and Bradford Counties belong to this group. The Bloss coal of Tioga County, the B coal of Lycoming County, the Bear Run coal of the Blossburg basin, and the A coal of the Bernice basin are considered by some geologists as belonging to this group.
2		Pottsville	Quakertown		Commercially unimportant.
1			Sharon	(Block) (Quakertown-?-in Warren County) (Upper Marshburg in McKean County) (Railroad seam along Pa.-Md. line) (Mehoopany in Wyoming County)	Commercially unimportant but formerly extensively mined in Mercer County.

Pennsylvania First to Correlate Its Coal Seams

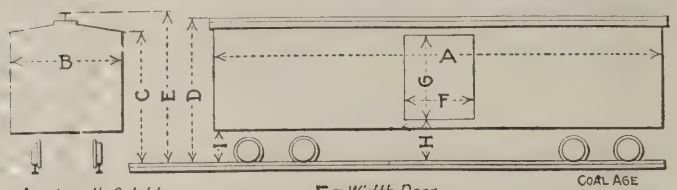
As Pennsylvania was the first state to correlate its coal seams and adopt official names for them, these names have been accepted as a standard to which all the Carboniferous coals of the country are referred.

The table of bituminous coals covers all of the seams found in Pennsylvania, from the lowest shown at the bottom consecutively up to the highest known coal in the state. Under the column headed "Formations" is shown the division of the coal beds into the distinct geologic formations which have been recognized. The old formation names are shown in parentheses and the official names in bold-face type. The Monongahela and Alleghany formations are by far the most important, and yield nearly all of the coal mined in this state.

In the column headed "names of coal beds" is shown the official names of the coals while the adjoining column shows the more important local names applied to these coal beds in different districts.

The column of index numbers refers solely to a similar column in the table of mining districts for the purpose of locating the more important coals being worked in the mining districts of the state. They have no official connection with the names of the coals. In the first column of the table of mining districts will be found a series of numbers which refer to the numbered circles shown on the map indicating the important mining districts of the state.

Pennsylvania is the leading coal mining state of the Union. Besides embracing the only anthracite deposits of importance in this country, it stands first in the production of bituminous coal. The entire anthracite industry is confined within a small area of 480 square miles in the eastern half of the state.



The bituminous field occupies the greater portion of the western half of the state, and forms a part of the Appalachian coal field which extends southward into Alabama, across the intervening states. The area of this great coal field, lying within the state of Pennsylvania is 14,200 square miles, and the available supply of coal remaining in the ground has been estimated by the U. S. Geological Survey as approximately 108½ billion short tons. This amount of coal would supply the entire United States, at the present rate of consumption, for a period of approximately two and one-quarter centuries. The bituminous fields contribute about one-third of the total coal production of the United States, more than 95 per cent. of which is mined in the districts shown on the accompanying map.

Squeezing Him If He Is Not Careful

Required Clearances for Freight Cars

In the designing of structures adjacent to or straddling railroad tracks, it is most important that the maximum clearances required for the class of equipment

A = Length Outside
B = Width at Eaves or Platform
C = Height, Rail to Eaves
D = Height, Rail to running Board
E = Height over All
F = Width Door
G = Height Door
H = Height from Rail to Door
I = Height from Rail to Floor
For flat cars D is height from Rail to Top of Platform

DIAGRAM OF FREIGHT-CAR MEASUREMENTS

used, be accurately determined. Data of this kind are frequently difficult, if not impossible to obtain. As a result it often happens that expensive alterations are necessary on construction work of this character.

*Approximate.

Not only is it necessary to anticipate the kind of railroad cars it is expected to load at the plant under consideration, but due attention must be given to all kinds of equipment which are liable to pass over the tracks in question. It is often the case that the very largest kind of a car may be shunted into a mine siding during the process of switching operations. Where such a contingency is liable to arise, it is obvious that due preparations must be made for it. The accompanying table and sketch, taken from the *Iron Trade Review*, gives the principal overall dimensions of various types of cars on the American railroads. Even though the list is necessarily incomplete it may be taken as typical and will be of material assistance to designers of mine structures.

Coal in Eastern Montana

An account of an area of workable coal recently examined by G. S. Rogers, of the U. S. Geological Survey, in the northern part of Big Horn County, Montana, three or four miles from Waco, on the Northern Pacific Ry., has recently been published.

The coal-bearing area lies on Pine Ridge between Yellowstone and Big Horn Rivers, at the head of Mission and Sorrel Horse Creeks, beginning about 8 miles southeast of Custer, and capping the ridge for 6 miles.

The coal is of a good sub-bituminous grade. In physical appearance and stocking quality, it is described as superior to the coal mined near Sheridan, Wyo., but somewhat inferior to the Red Lodge and Bearcreek coals.

No development has taken place, but from samples procured in adjoining areas to the east, it is concluded that the Pine Ridge coal will prove to have a heat content in excess of 10,500 B.t.u. The bed has a thickness of more than 30 in. throughout the area of 5 or 6 miles, and is more than 3 ft. over much of this territory, attaining at one point a thickness of 4½ ft. In the northern part of the area the coal is much affected by faulting, but the best fuel is not disturbed.

It is estimated that more than 20,000,000 tons of coal underlie the field examined, of which at least 60 per cent. is recoverable. It is possible that other fields south and west of the district examined, are also underlain with workable deposits.

This report is published as Bulletin 541-H, a copy of which can be obtained on application to the Director of the Geological Survey, Washington, D. C.

In rebonding old tracks, it is often advisable to use exposed bonds, since if the splice bars are removed from the old rails, the bolts frequently have to be cut, and it is often impossible to draw the plates back into their original space.

An Unusual Underground Organization

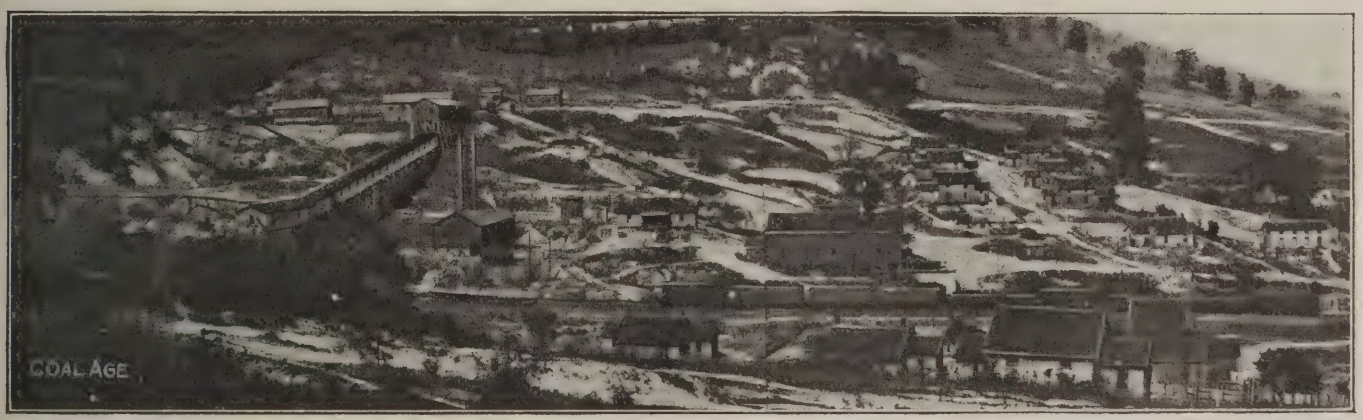
By G. S. Brackett*

SYNOPSIS—During the past few years the small coal mine is the only one that has been making any money. The results obtained by reorganizing a large mine into practically a collection of little ones have been decidedly encouraging.

It has been a common maxim, during the recent years of small net earnings in coal production, that the only mines showing a reasonable margin of profit are the small ones with an output of 100 to 200 tons daily and a correspondingly small acreage.

These mines are worked by pick mining, without power equipment, and a short haul on the mine stock due to the small field of coal. The virgin tonnage is not sufficient to permit of much outlay in capital for the installation of any machinery; the long main heading and expensive track over which hundreds of acres of coal must be moved are replaced by short room headings, some feeding direct to the pit mouth.

To assume conditions in the smallest of these mines, the drivers coming to the tipple probably dump their own cars, and return to the mine with the same empties, and the only necessary outside laborers are the trimmers on the railroad car. Probably the foreman is the blacksmith, and the mine-track work is done under his supervision by the drivers after the miners have cleaned up, which, in a pick mine, usually occurs early.



Pick mining gives less trouble with falls of roof, there are no wiremen, power-house employees or expensive salaried men; only a small equipment of mine cars is required, and these are not subjected to the unusual strain of motor haulage, and the mine-supply account is a small item. The coal is sold through a regular dealer and one of the firm or partners keeps the accounts.

There is a growing partiality among miners for pick mining and labor shortages are rarely felt in these small operations, especially if "solid shooting" is permitted as it is in many such cases. The delivery costs are small, and the net earnings correspondingly large but the proposition of tenfold production and tenfold profits looks extremely attractive. The larger mines, however, rarely work out in this direct proportion.

The object of this article is not so much to complain of the conditions existing in the coal-mining business, as to give the results of a radical change made in the underground organization of the employees of the Pittsvein Coal Co., so that many of the difficulties met with in larger mines are eliminated and the production costs brought down to a point more in competition with the smaller mines and their efficient labor.

The Disadvantage of Growth

The small mine has increased its tonnage, the haul has become so long that an electric motor has been installed together with a power house, the track relaid with heavier steel and heavier ties. The mine cars and track need constant attention. There is a complete tipple force, and instead of paying the drivers a little extra for track work we have regular track men. The stage is reached where the foreman is a foreman only and the superintendent is created.

Mining Plant and Town of Pittsvein Coal Co., at Flemington, W. Va.

Some of the headings pass through local dips and pumps and pumpmen are required. The cost per ton is considerably higher than in the small mine, shut-downs are expensive since much underground work needs doing, and the power house must be kept running. The expenses of monthly men are also high.

A reasonable economy is the installation of electric cutting machines to reduce the cost of the coal on board the mine cars at the working face. Most of the miners quit because they do not like machine-cut coal, and those that stay are continually complaining and "bucking" the mining machines. The tone of the mine is contention and dissatisfaction—it is difficult to get sufficient miners and those that are obtained are of the poorest class. The timbering is bad, the falls frequent, the rock expense high and accidents are numerous.

The production does not meet the expectation of the owners and the profit has gone entirely to the other side of the ledger. There are pump men, wire men, track men,

*Pittsvein Coal Co., Flemington, W. Va.

assistant foremen, boss drivers, rock men, timber men, carpenters, blacksmiths, trappers—each and every one out for his day's wages only, and determined to do nothing that is not compulsory. The trackmen will not fix a wire, nor open a ditch; the drivers will not clean a switch, the rock men will not set a timber and the timber men will not start a pump. That is, they will not unless the boss happens to be there and tells them to.

The boss' or the assistant's hands are full keeping in touch with these little things—he makes his rounds daily and finds that a "turn" is needed in the third left heading and a crosscut switch on the sixth right. He hunts up the trackmen and sends them to the third left with instructions to go thence to the sixth right. Any mining man knows what happens—the tool house must first be visited, a bite to eat, hunt the spikes, the bender, forget a hammer and there is always one who must fix his carbide lamp just as the rest are ready to start.

The worst of it is that the same thing happens on the return trip and continues *ad infinitum*.

Piles of spikes are left wherever a job is finished, insulators are abandoned in roof and rib, timbers are scattered over the mine; rails, switches, frogs are found any place. Each pile of wasted material acts as a silent instructor to all employees to continue to waste. All the men will pass over or by a place that needs fixing time and time again, leaving it for somebody else to repair. The first idle day there is work to do all over the entire mine and the shut-down will cost as much as a full day's run.

The drivers do not haul half the coal they ought, all the work is inefficient and the maintenance and repairs fall behind. These conditions might be an exageration but they pertain in part in all mines, and the bigger the mine the more pronounced. The cost of production goes up—up—up.

Revert to Simplicity

What is the logical relief? Get back to that simple organization, where a large mine is an aggregation of a number of small mines, where every employee sees the man in charge of his work several times daily, and the man in charge has a territory so small that he can keep track of every spike, rail, timber and tool and know every fall, every shot and every trip the drivers make.

He visits the working places several times a day, examines and directs as to timbers and roof, fixes a pump, opens a ditch or hangs a piece of wire. He has time to help with a fall, to help with a crown timber, and (most of all) to know and work with his men; to teach them and prevent accidents.

The mine at which this experiment in organization was made is in West Virginia, where the State Department of Mines is increasing its demands, restricting certain practices, and insisting that there is someone personally responsible for most of the accidents. The injured man should have had props in his working place, his roof should have been examined more frequently by the foreman or a safety prop should have been set. The injured man was not experienced enough to be expected to use the necessary precautions.

Entirely aside from the state law, these statements cause the foreman and superintendent some pangs of conscience. Could life be saved in the mine if more careful supervision was enforced—and can this supervision be given without prohibitive extra cost?

The local conditions at the mine in question are worse than the average, the roof is draw slate, heavy and treacherous, the local dips and drainage difficult, clay veins are frequent and labor is a little below the average in quality and experience. Assistant foremen were necessary for rather smaller tonnages than usual. Even with this aid it was almost impossible to visit the working places with the proper care and give the proper attention to the drivers and day men without a prohibitive cost.

These conditions vary greatly in different mines, some requiring more attention than others; but the difficulties constantly arising in this particular mine made an unusual amount of attention necessary, both on account of the irregularities in the working places, and the effort to prevent accidents from the dangerous roof.

Small Sections Were Created

In revising the organization the mine was divided into sections, each working 15 to 30 miners and an adequate number of drivers hauling to an independent motor side track. The foreman's assistants were disposed of, the track gang, pumpmen and brattice men discontinued; and each section given into the entire charge of an energetic practical coal miner, one who could lay a switch, string electric wires, had some ability in handling men and was a good timber man.

It is not difficult to pick out one such man in every 25 to 30 employees. His wages were based on hours, an increase being given over ordinary track rate so as to make the job worth working for. He can cover his territory carefully twice daily and still have ample time for other duties. He does a great deal of track work, timber work, and rock work himself.

This man's efficiency is based on the following points: Lack of accidents; cost of his tonnage at side track; salvage of used material of all kinds; conditions of track, timbering, brattices and drainage; enforcement of state mine law and company rules.

This small section is his own mine, his own responsibility and it is all close to his hand, with his tools and mine material convenient. He looks after his own pump, his own drainage and ventilation. He has authority to allow day time to a miner for helping clean a fall or build a brattice, and is usually present himself to help with the work.

He is busy, just as was the mine foreman of the small mine, but his work is compact and his job worth holding as he has taken a step above common labor. He gets help from a driver who has finished early, or from a loader out of coal; and in the larger sections he has one regular track man.

He knows every inch of his section, every prop, every wood rail, every bad track joint; he has in his mind all the little jobs that need attention and is in so close touch with all the men that these little jobs get done at odd times while the mine is running. Timbering rules and regulations are enforced and the drivers do not "soldier" the latter part of the day for a car or two they are expecting to get.

There is no time lost by the inside labor traveling diagonally across the entire mine and back. If a car is off the track, this individual is close at hand with a jack and the coal continues to come. If there is a fall on the heading he is not far away and drivers and miners alike are soon at work and the road cleared.

The personal interest exhibited by the men in their own sections and the rivalry between these sections are what produce the results. The work is done, and should the mine lie idle we are not faced with intolerable conditions and unbearable expense.

The section men are worth taking care of during shutdowns, they are the only expense incurred, and each will have some improvements to make in his own section, or they may combine and lay some heading track, or attend to some main drainage.

On the mine foreman rests the success of the system to its last degree or refinement. He has time in making his rounds of inspection to give every little detail of economy and safety his close attention; and he must inspire and maintain in the section men the desire to produce coal on an economical basis, to work for the benefit of the company, and that each man should endeavor to have his section in just a little better condition than his neighbors.

A Few Simple Rules Were Adopted

The normal tendency in mine organizations is to increase in complexity as the operation expands. The principle of the section method is to eliminate the complications and get back to simplicity. A large mine is only a combination of small ones feeding into a trunk line haulage road; and each mine (or section) is entirely independent with the policy and government of all administered by the mine foreman on a standard system of rules.

Tipple and Conveyor, Pittsvein Coal Co., Flemington, W. Va.

These rules need not be so numerous and complicated that a book form is necessary. In this particular mine, sixteen rules were selected with eight subdivisions, easily understood and remembered, covering the causes of accidents. They are simple instructions to the section men, and must be enforced.

In Addition to the State Mine Law the Following Rules Must Be Observed

(1) Make a written daily report to the office on the blank forms furnished, showing mine conditions.

(2) Place "Danger" boards at all abandoned places.

(3) A regular system of timbering must be adopted for each condition, suitable cap pieces being furnished with the props.

(4) Permanent brattices must be of incombustible material.

(5) The mine humidity must be 95 per cent.

(6) All electric wires must be securely hung, and free from "grounds," with connections carefully made. They must be boxed at all crossings. A "Danger" board must be placed where men are likely to come in contact with the wires. Coils of "live" wire must be marked with "Danger" and placed to one side.

(7) All haul roads must have a clearance between car and rib of 2½ ft.,—or whitewashed refuge holes every 60 ft.

(8) Dangerous slate on the haulroads must be secured or removed promptly upon discovery.

(9) The brakeman must always be at the rear of the trip before it starts.

(10) Drivers must not ride on the front end or between the loaded cars.

(11) At all times there must not be less than two experienced men on all pillar workings.

(12) Props in the rooms must clear the car by 12 in.

(13) There should not be less than three props and cap pieces ready for use, in all places requiring timbers regularly.

(14) Every working place not marked with a "Danger" sign must be visited twice daily. After an idle day the first visit must be made as promptly as possible in the morning.

(15) "Exit" arrows must be placed throughout the mine showing the way to the nearest opening.

(16) All employees must be instructed in the particular dangers incident to their work, and furnished a copy of the mine law and company rules; and attention called to the following safety rules:

(a) Employees must not work in a place in need of timbers, or known to be dangerous.

(b) Nobody is permitted to ride on loaded cars underground, except those whose duty requires them to do so.

(c) Men riding in an empty car should put their tools in another car.

(d) Remove your lamp from your hat while handling explosives.

(e) Examine your roof FIRST,—and do not enter after firing a shot until the smoke clears so that you can do so.

(f) Use a copper needle and keep an axe.

(g) Do not drill out a shot that fails—bore another hole.

(h) Miners must properly prop and secure their working places, and order the necessary timbers from the foreman or assistants at least one day in advance of their needs. Miners must keep not less than three props and cap pieces on hand ready for use and emergency at all times.

A suitable form is used on which the report of each section is rendered daily, countersigned by the foreman and kept on file in the office. All cases of violation of the rules are noted, recommendations made and material ordered, and the notation continues until relief is given. It is needless to say that, with these reports going to the office, there is rarely a repetition of any complaint.

There was a little difficulty experienced in getting men to take charge of the sections, as the State Department had adopted the policy of holding inquests after all fatal accidents, and the feeling among some of the men was that this system shifted the responsibility to some "under dog." One of the advantages of the system was to take undue responsibility off any one person. If the section men follow their rules, report any violation, make their recommendations and order the necessary material, they have done all they have any authority to do; and the responsibility rests higher up.

The Proper "Spirit" Was Important

In starting the system there was some trepidation on the part of the management as to getting it going in the proper "spirit." Great care was taken in the selection of the men. The spirit, or general tone, of the employees in any industry, is of greater importance than is generally supposed. There is a vast difference in costs when every employee is determined to shirk, and when every employee is endeavoring to help, and the difference increases directly with the number of employees. One section, the smallest, was left under the care of the foreman to serve as a model, but was found unnecessary for this purpose.

There was no standard system of timbering adopted, as the character of the roof varies considerably, and the most satisfactory method depends entirely upon the conditions. Verbal instructions are given in all cases to the

section men frequently after a consultation as to the most advantageous method for any particular case.

The practice in this region is to pay the miner for certain "dead" work which he performs, such as gobbing roof slate or clay-vein rock, pumping or bailing water, shooting up a roll in the pavement or cleaning a fall in his working place. It can easily be seen how this expense may be greatly increased unless care is exercised by the foreman.

Miners have been known to encourage a fall in their working place in order to get the work and allowance for cleaning it up. The amount of water bailing is rarely as arduous a task as the miner pretends, but the foreman finds it a hard matter to take the necessary time to determine just how much work the miner does.

It is in allowances of this kind that the section system has shown a great improvement in costs. Every little thing is under strict and detailed supervision, and even with this supervision the amount of actual work which the section man can get done himself is surprising. The reason of this is that his section is small, he loses no time traveling over thouands of feet of headings, he knows just exactly what needs doing and the tools and material are convenient.

He is commended if he collects a pile of scrap copper in his tool box or a pile of recovered timbers along the heading which under the old system nobody had time to get together. The spirit of waste is replaced by the proper care of all supplies. The actual cost of production was decreased in both labor and material. This decrease was considerable, and with it was the remarkable feeling of security in that the general conditions were improving and not on the decline.

The Main Causes of Accident Were Attacked First

The original object in starting the system was to reduce the accidents by insisting upon a better method of timbering and by a more careful and frequent examination of the roof in the working places. Fifty per cent. of all fatal accidents are caused by falls of roof and coal; explosions, mine cars and motors are the next most prominent. The question of explosions is entirely too extensive to put under the care of the section men, and is eliminated from this general system, being included only in the province of the foreman.

In carrying out the idea of simplicity, and rather than confuse the minds of many of the workmen with too numerous safety rules, the campaign was started on two points only, the roof and mine cars. A few hundred feet inside the pit mouth the workmen cannot fail to see an illuminated sign reading:

Examine Your Roof First
Do Not Enter Your Working Place
until Smoke Clears

He sees this same sign many times before he reaches his working place. It is further impressed upon his mind with the visit of the section man to inspect his roof and detect any weakness. There is a second visit of the section man later in the day.

Ample whitewashed refuge holes are provided along all haul roads, and the following sign is placed frequently:

Do Not Ride
on Loaded Cars

At the junction points of all haulroads used by drivers the following sign is placed:

Drivers Must
Stop
Look
Listen

The drivers are instructed not to ride on the front end or between the loaded cars, and they are not permitted to do so.

The constant drumming of these simple rules has the effect of starting each individual to thinking of the other dangerous practices in which he indulges, and by so doing a careful miner is finally produced; while a long list of safety rules would only serve to discourage him.

The men are taught in what way to be careful and are constantly reminded of dangerous practices and these are the integral parts of safety first. To pick out all the various causes of acidents and instruct each miner regarding them would be an impossible task and would be of no value unless the man himself had the inherent desire to protect himself.

This can only be brought about in many cases by making his lessons numerous and simple, and then his education along this line will continue voluntarily. The section system teaches the men the simplest and most important rules of care, and where necessary insists and commands that they be obeyed.

In the mine in question, accidents have greatly decreased. The output is more regular. Foreign holidays are not so seriously felt as there is a concentrated effort on the part of every section man in the early morning to get those men who are in the mine to load a large turn. There is less trouble with the miners "out of coal" on account of the failure of the machine to cut the place.

I am enthusiastic in my statement that the mine has been run with less friction, on a safer basis, and at a cheaper cost than under the old system of boss, assistant boss, driver boss and track boss.

Notes on the Coal Situation in Peru

Conservation of the coal properties of the republic was several regions certain lands containing coal were withdrawn from denouncement. The government's desire to develop the fuel production of the country is manifested in its willingness to facilitate the building of railways in the coal-bearing regions. Studies have been made of the districts of Hatunhuasi, Oroya to Huansyo, Sayan to Oyon, and Cheeras, in which districts large coal deposits exist. The government hopes eventually to interest foreign capital in the opening of these districts. The annual importation of foreign coal is valued at about $1,099,000, most of which comes from England, Germany (briquettes), and Australia—from the latter country in sailing vessels. American exporters of coal should be able to compete favorably with these countries after the opening of the Panama Canal.—*Daily Consular and Trade Reports.*

When scaling indicator diagrams, the pressure to be taken is that immediately at the end of the compression period, not at the end of the delivery, for it is invariably found that the pressure of the air falls off after the valves have opened.

Commutating-Pole Motors for Mine Locomotives

By R. E. Hellmund and W. A. Clark*

SYNOPSIS—A reply to a former paper printed in Coal Age, *this article vigorously advocates the installation of the commutating pole on mine locomotive motors.*

In the issue of Coal Age for May 9, 1914, A. R. Anderson attempts to show that the adoption of commutating-pole motors for mine locomotives is ill advised. Since our experience along this line stands in marked contrast with the conclusions arrived at by Mr. Anderson, it may be of interest to the readers of his paper to have the matter presented in a somewhat different light.

Under the heading, "Interpoles are not new," Mr. Anderson mentions the first record of the idea of commutating poles which he has been able to find, also some experiments made by Mr. Sprague along this line in 1885. Undoubtedly, the historical facts as given are correct, but

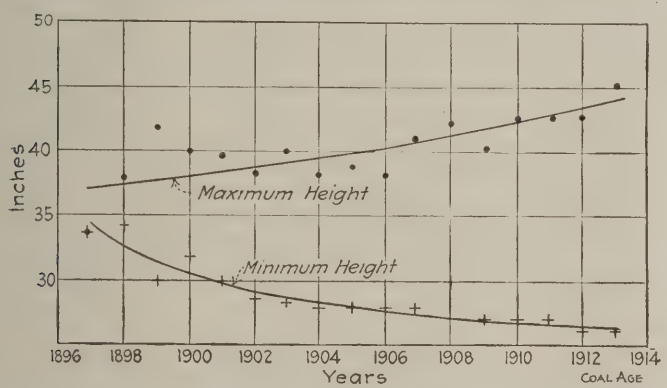


Fig. 1. Maximum and Minimum Height of Mining Locomotives

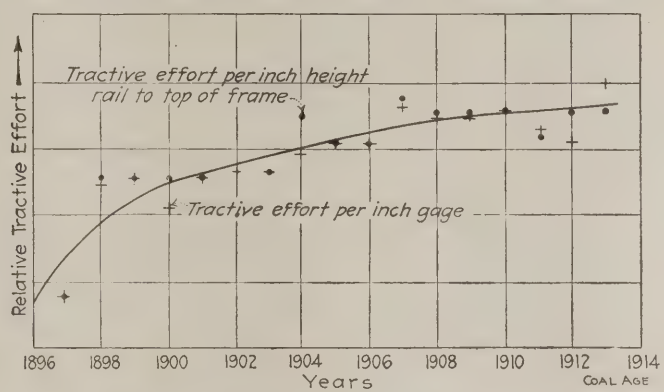

Fig. 2. Tractive Effort per Inch of Height and of Track Gage

they do not by any means furnish a complete history of the development of the commutating pole. Ever since the fundamental idea was first conceived it has been a number of times reinvented and numerous experiments have been conducted during the last 20 years by engineers in this country, as well as abroad, for the purpose of improving the commutation by means of interpoles or otherwise.

One of the writers took part in extensive investigations which were conducted by a German concern about 1899 for the purpose of finding means for improving the commutation of direct-current machines. The technical literature, as well as the patent records, of the various countries have numerous records of suggestions and attempts made to improve commutation.

We mention all of this merely because it is an almost indisputable proof that there existed a need for improvement on the old motor without commutating poles, or the many engineers of all countries would not have wasted their time in trying to find something better. The only reason why commutating poles were not adopted earlier than a few years ago, is because the laws of commutation were not well enough understood to enable the engineers to apply such devices economically. Ever since fairly reliable theories of interpole design have been worked out and published, the adoption of this contrivance has been almost universal.

We fully agree with Mr. Anderson that with liberal dimensions, fairly good commutation may be obtained with many machines which do not have to be reversed, and on which it is, therefore, possible to shift the brushes somewhat out of the neutral zone. In case of railway and mine locomotive motors, however, where the brushes have to be located in the neutral region because it is impracticable to shift them every time the motor is reversed, it is possible to obtain fair commutation, even with liberal dimensions, only under extremely favorable conditions.

For this and other reasons, to be mentioned later, it has become an indisputable historical fact that with the noncommutating-pole motors used for traction work, the consumption of carbons is from 3 to 10 times as large as with modern commutating-pole machines.

It is further a fact that with noncommutating-pole traction motors the commutator in many cases has to be renewed once or twice during the life of the machine on account of its having worn down. On the other hand, a replacement of the commutator for the same reason is practically unknown with the modern commutating-pole motor, although the life of these modern machines is considerably greater due to other improvements in motor design.

The Application of Interpoles

Under the heading, "With limited dimensions, use interpoles," Mr. Anderson states: "Another legitimate application of interpoles is found in motors where the dimensions for a given horsepower and speed are limited by the machine of which the motor is a part." Further on, he says, "In general, interpoles are desirable and properly applied in cases where the motor is subjected to overloads or where a large horsepower at a low speed is cramped into small dimensions."

We most heartily endorse these two statements because they give the most important reasons why we are advocating the use of commutating poles in motors for mine locomotives. To make ourselves perfectly clear, we will re-

*Westinghouse Electric & Mfg. Co., East Pittsburgh, Penn.

peat that we are advocating the use of commutating-pole motors in mine locomotives because satisfactory commutation cannot be obtained in such motors without them on account of the following facts:

1. The brushes must be located in the neutral zone and cannot be shifted to improve commutation on account of the practical operating conditions.

2. In mine locomotives the motor-space limitations are extreme, as will be discussed somewhat more in detail later.

3. The motor for mine locomotives is frequently subjected to overloads, as will be pointed out more in detail shortly.

Mr. Anderson discusses how it is possible to obtain cheaper machines by the use of commutating poles for certain sizes of motors, but he states that with the sizes usually employed in mine locomotives, the use of commutating poles will not give a cheaper design. We again fully agree with this statement and would add that in small motors such as are used for mine locomotives, it is a common occurrence that the use of commutating poles increases the cost of manufacture.

It should, therefore, be evident that the manufacturer furnishing commutating-pole motors in spite of their higher cost can have only one object in view, namely, to put out an improved product and to give his customers better service and satisfaction.

To the further statement that the commutation is but little improved under working conditions, we wish to take exception and refer back to the facts we previously gave regarding the decreased brush and commutator wear made possible by the use of interpoles. The statement that commutating poles may cause additional expense and trouble for the operator, we will discuss later.

The Coefficient of Adhesion

Under the heading, "A locomotive can only exert a certain pull," Mr. Anderson attempts to show that a properly designed mine locomotive cannot be overloaded. He states that the maximum load depends upon the coefficient of adhesion between the locomotive wheels and the rail, which latter statement is quite correct. He is wrong, however, in connecting a coefficient of adhesion of 20% to 25% with this discussion of maximum possible load, since it is a fact well known to every engineer connected with traction work that a coefficient of adhesion of 33% is not at all uncommon, and with sanded rails, the coefficient of 40% or possibly somewhat higher, may be obtained. Moreover, where the brakes are used to prevent slipping of the wheels, the motor load may correspond to a considerably higher adhesion. The only way to prevent the motor from overloads would, therefore, be to design it with a rated capacity corresponding to a coefficient of adhesion of at least 40 per cent.

Further on, Mr. Anderson states: "Since there is nothing to prevent the motor from being operated continuously at this maximum horsepower (he refers here to the horsepower dependent on the maximum coefficient of adhesion) while the motor is in operation, the motor equipment should be at least large enough to meet this condition." The incorrectness of this statement is self-evident because it is a commonly known fact that in practical operation train resistance for numerous reasons varies over wide limits.

The resistance of a given train is certainly greater going up hill than it is going down hill; it is larger on a curve than on a straight track; it takes more tractive effort to accelerate a train than it does to keep it in motion; all this is beyond doubt.

How is it possible then with such unavoidable variations that the motors continuously exert the maximum possible tractive effort? Another reason why the maximum possible motor load cannot be maintained continuously, or even for an hour, is because the coefficient of adhesion depends so thoroughly upon the varying conditions of the rails, that it is practically impossible to maintain its average anywhere near equal to the possible maximum.

The practice of rating the motors continuously, or even on a one hour basis equal to the possible maximum, of say, 40 per cent. adhesion just in order to make overloads impossible, would be wasteful not only in first cost, but also because a motor of such size would have a low efficiency and consequently high power consumption at the average load under actual operating conditions.

But Mr. Anderson proposes to go even farther and states: "The correct motor equipment for industrial haulage and especially mine haulage, must have a normal capacity, at least equal to, and preferably 10 per cent. to 15 per cent. greater than the maximum tractive effort which a locomotive can develop, etc." In other words, Mr. Anderson proposes to use motors with a normal rating 10 per cent. to 15 per cent. bigger than can be utilized at any time, and about 100 per cent. larger than is needed. A close study of the locomotives offered to the trade reveals the fact that none of them have a horsepower rating equivalent to a coefficient of adhesion of 44 per cent. to 46 per cent.

Customary Ratings of Motors

The same study will also show that it is common, uptodate practice to employ motors having a one-hour rating corresponding to a coefficient of adhesion of from 15 per cent. to 25 per cent. and a continuous rating, corresponding to less than half these values. This means that all locomotives at present available to the trade may be overloaded whenever the coefficient of adhesion is as high as 30 per cent. or 40 per cent., and it will be remembered that Mr. Anderson himself says "Interpoles are desirable and properly applied in cases where the motor is subject to overloads, etc."

Under the heading, "Sufficient space is usually available," the statement is made that sufficient space is available in practically all types of locomotives to permit of the design of good moncommutating-pole motors. While the conception of a good commutating motor is flexible and largely a question of opinion, it cannot be denied that the brush and commutator wear on practically all noncommutating-pole machines is from 3 to 10 times as large as with modern commutating-pole motors. And while the operator of mine locomotives may not be much interested in just how good the commutation of his motors may be, he is vitally interested when it comes to bearing the expense and suffering the delay caused by replacing carbons and commutators, or dealing with such other troubles as are liable to occur with noninterpole machines. These will be discussed later on.

But, even if it were a fact that fairly good commutation could be obtained in a frame of given dimensions, this would surely not be a sufficient reason for not build-

ing something better. It is undeniable that commutating-pole motors commutate better than non-commutating-pole motors. Fully 90 per cent. of all direct-current machines of 10 hp. and above are now being built with these poles for the purpose of improving the commutation.

With regard to the space limitations imposed upon the designer of mine locomotives by the existing conditions, we wish to state that in 16 years of experience in designing motors for all kinds of applications, we have not found a case where the space limitations were as exacting and extreme as in mine locomotives, where the motor is limited in width, breadth and height, as well.

The narrow gages used for mine locomotives limit the axial length of the motor to a few inches. The desirability of obtaining the maximum tractive effort from a given machine by using the smallest possible pinion, limits the gear-center distance and therefore the horizontal width of the motor while restricted head room limits the height of the motor.

which may spark under certain conditions, to a commutating-pole motor, which ordinarily will not spark.

Mr. Anderson states that the installing of commutating-pole motors is equivalent to installing so much additional and unnecessary apparatus, from which there is liability to breakdown and for which repairs must be carried in stock, etc. He further gives a view of the wiring of a noncommutating-pole motor and a complicated diagram of a commutating-pole motor.

Only Two Interpoles Are Needed

Instead of adding four poles, as shown in this drawing, it is quite sufficient except in large motors, to install two commutating poles and coils. The poles proper are pieces of flat rolled steel, bolted to the frame, and require no attention or repair. From Fig. 4, this is self-evident. The two commutating-pole coils—one of which is shown in this figure—are in structure similar to those for the main poles. It is well known that the trouble caused by modern field coils is practically *nil*, as com-

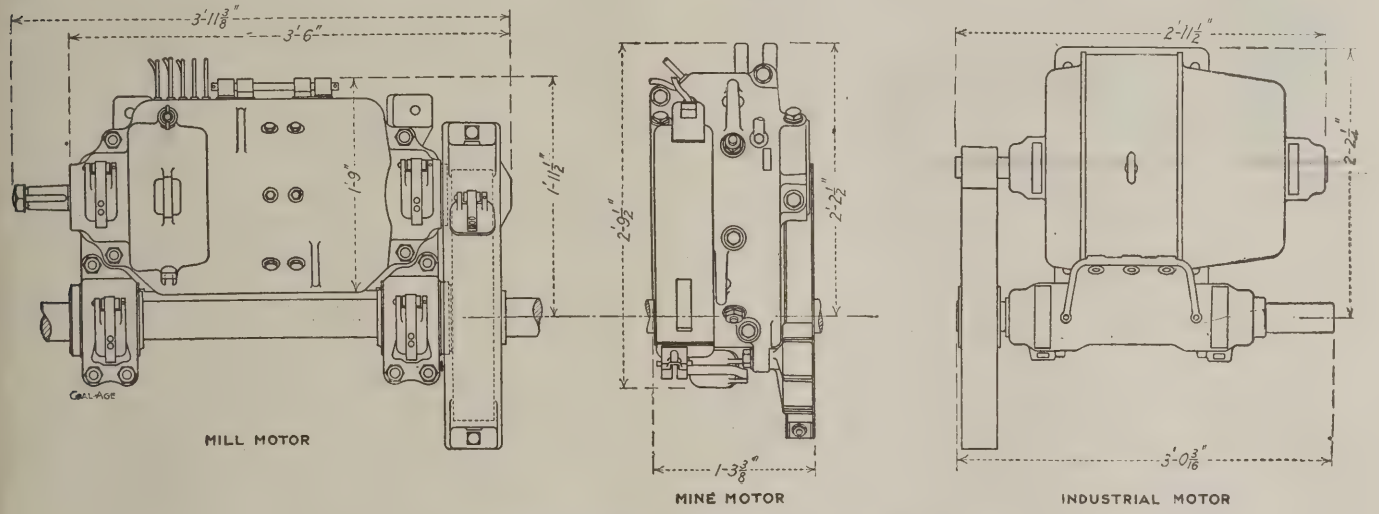

Fig. 3. Relative Sizes of Various Types of Motors

We give herewith two curves taken from a paper by G. M. Eaton, which demonstrates the fact that these conditions are becoming more and more exacting every day. One curve shows the minimum height allowed for mining locomotives over a period extending from 1896 to 1914. It will be seen that there has been a continuous decrease in minimum head room. The other curve shows the relative tractive efforts obtained per inch of height of locomotive as well as that per inch of gage. It will be seen from these curves that there exists a continuous demand for increasing the motor rating, crowded into a certain space.

Fig. 3 shows a mine-locomotive motor, a mill motor and an industrial motor all drawn to scale. These are all commutating-pole machines and have approximately the same nominal rating. This illustrates clearly how it has been necessary to condense machines for mine-locomotive service.

Under the heading, "Commutation Is Not Always to Blame," Mr. Anderson intimates that sparking and its destructive effect are not always due to motor design. While it is quite true that excessive vibrations and commutators out of round may cause sparking, we do not see why one should prefer a noncommutating-pole motor pared with that experienced with brushes, commutators and armatures of motors without commutating poles.

The installation of commutating poles means, therefore, the addition of a few extremely simple parts, which are not subject to wear and which practically never give trouble, for the purpose of eliminating marked wear, much trouble and the necessity for repair.

Fig. 5 shows a commutating-pole motor with all necessary wiring, as it is actually installed by the Westinghouse Electric & Mfg. Co. This is in marked contrast to the sketch given by Mr. Anderson, in an apparent attempt to make the connections look as complicated as possible.

A few other points may be of interest in connection with the question of commutating-pole, versus, noncommutating-pole motors.

The absence of interpoles and the consequent poor commutation often leads to other troubles. Bad commutation means, in most cases, a quick roughening of the commutator. A failure on the part of the operator to smooth this by sandpapering, or even turning, will result in vibration of the carbons. Thus, a replacement or repair of brush-holders is often made necessary by the absence of commutating poles.

Bad commutation and the consequent wearing and breaking of carbons also, frequent sandpapering of the commutator, all lead to the accumulation of carbon and copper dust inside of the motor. This forms a good conductor and is often the cause of insulation breakdowns and consequent burnouts of the various parts of the motor, meaning again, additional expense for repairs and operating delay caused by the absence of commutating poles.

Again, bad commutation means that the commutator, instead of assuming a polish, will blacken and cover all over with a film of carbon and copper. This leads to the breaking down of the insulation between the commutator segments, and an arc flashing over between the brush-holders. This arc, when once established, will sometimes

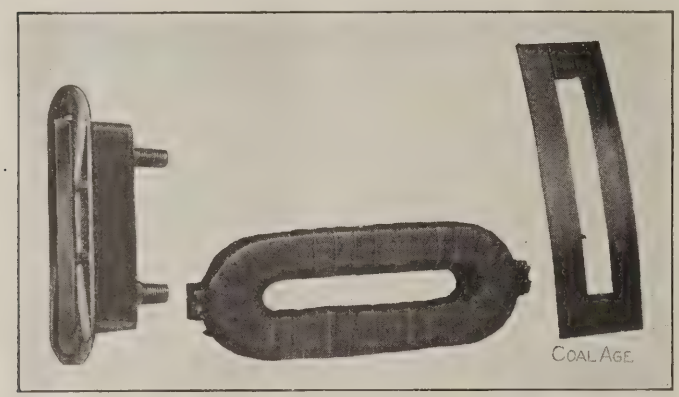

FIG. 4. THE THREE PARTS OF THE COMPLETE COMMUTATING POLE

burn holes into the commutator copper; sometimes, it will burn the insulation of the commutator V-ring, while at others, it will even burn the insulation of the armature and field coils in the neighborhood of the commutator, necessitating the replacement or rewinding of these parts with attendant operating delays.

The operation of the commutating-pole motor stands in marked contrast to all this. An interesting case, which has come to the writer's attention, and which is typical of the limited inspection with which a commutating-pole

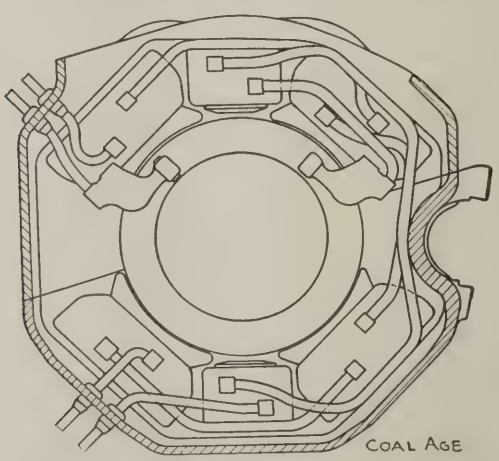

FIG. 5. CONNECTIONS FOR MOTOR WITH TWO INTERPOLES

motor may be operated, is the first locomotive furnished by the Westinghouse Electric & Mfg. Co., supplied with commutating-pole motors. In this case, it had not been necessary to open the motor during 18 months of service, nor even to remove the commutator cover to inspect the motor. After two years' and ten months' service, it had not been necessary to make any repairs or to even replace carbons.

Similar results have been obtained with most commutating-pole motors.

Special reference might here be made to the fact that commutating-pole motors have given so good results in connection with trolley-car and heavier traction work, that it is practically impossible nowadays to sell anything but this type of machine in this line.

In conclusion, therefore, it may be stated that those manufacturers who have spent large sums of money for developing commutating-pole motors to supersede their old lines of noncommutating-pole machines, have done so after carefully considering the merits of the case. And they have succeeded in giving to the trade a vastly improved product.

Don'ts for Superintendents

Don't fail to have safety gates at the top and at each lift of every shaft and heavy pitch slope wherein men are lowered and hoisted.

Don't fail to provide safety overwinding devices on all shafts where men are lowered and hoisted.

Don't fail to provide safety switches or blocks above all breakers to safeguard loaders.

Don't fail to have doors and stoppings constructed as required by the mine law.

Don't fail to provide every mine with a sufficient number of danger signals or signs.

Don't fail to see that all rules are observed for the handling of explosives.

Don't allow any person in a state of intoxication to go into any mine.

Don't fail to observe the mine law pertaining to ventilation so as to maintain healthful and safe conditions.

Don't fail to observe the law relating to sinking new shafts.

Don't fail to use every precaution to insure the safety of the workmen in all cases.

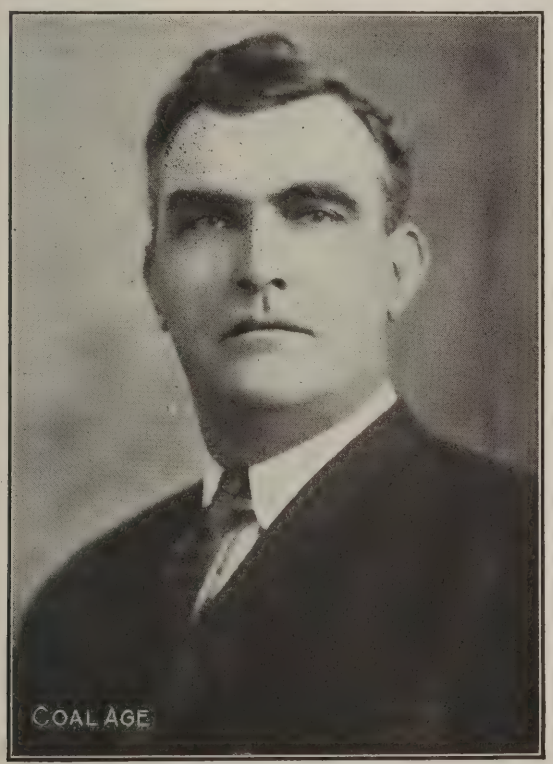
Don't fail to provide an efficient alarm or light to be attached to the front end of every trip pushed by a motor inside the mine.

"Too Busy To Read"

He is a familiar type—the fussy, fretful man who imagines that he is about the busiest fellow in town. He often dumps in the waste-basket unwrapped copies of business or technical magazines that contain valuable articles bearing directly on his problems. He fondly believes that he is too busy practicing to bother with what others are preaching.

The trouble with this type of man is that he has not learned that the real executive is the man who so plans his work as to leave a reasonable amount of time for reading and planning.

There are shoals and breakers ahead when the accumulation of new ideas ceases. The man who declares he has no time to read is unconsciously advertising his small caliber, his slavery to detail, his arrested development.—*Printer's Ink.*



Note—Taken from Susquehanna Coal Co.'s book of instructions.

Who's Who in Coal Mining

Robert Marshall Irving

There is one race to which the coal industry is greatly indebted for many of its men, its ideas and traditions. Just as a duck takes to water as its natural element, the Scotchman takes to coal mining as his life's work. And, as a general rule, they don't remain at the digging game very long, for their proficiency usually brings advancement to positions of trust and authority.

Over in Ayrshire, Scotland, about the year 1870, Robert Marshall Irving had a son, who was named Robert Marshall, Jr. When the boy was 10 years of age, he began working in the mines in Ayrshire, and continued

R. M. Irving

at this employment until he was a young man of 20 with hard muscles and plenty of experience in digging coal from the bowels of old mother earth. Scotland isn't a very large country and Robert discovered that there were more people there to the square mile and fewer opportunities than there were in the newer world across the ocean. So, in 1890, he emigrated to America, landing in Blosburg, Ala.

Just as soon as he could get his overalls on, he started work in a mine in Jefferson County, later changing to another mine in Walker County, Ala. After two years of such employment he started north, landing in the Block coal field at Knightsville, Ind., in 1892.

After five more years of hard, earnest work in the Indiana mines, he secured a job as pitboss; this gave him a hold on the ladder that leads upward, and neither elements nor men have been able to shake him loose.

It wasn't very long after this when Mr. Irving was advanced to the position of mine superintendent, which job he held for nine years, resigning the place to accept employment as a district mine inspector in Indiana. The duties of this latter position occupied his attention for five more years, when his experience and ability were recognized through his advancement to the general superintendency of the Monon Coal Co., with headquarters at Terre Haute, Ind. He has served four years with his present company.

At the inauguration of the Mine Inspectors' Institute of America, held at Indianapolis, Ind., Mr. Irving was elected third vice-president of that organization. Like most men who have aspired to be something more than a miner, and yet who have not had the advantages of an early education, he has been compelled to gather his theoretical training at odd moments when the opportunity was afforded him. It is this kind of training that sticks best, for it is always gained through much personal sacrifice. Mr. Irving's night study enabled him to complete an entire correspondence course in mining, which training, added to his years of experience in all positions from miner to super, has rounded him into a coal official, whose opinions carry weight in the field of his employment.

War Makes Many U. S. Citizens

There has been a marked increase in the number of applications for first citizenship papers at the prothonotaries' offices in the anthracite region of Pennsylvania since the outbreak of the European war. None of the companies report the loss of many men by the return of foreign reservists, and some say that they never before had so many men on their payrolls.

There is probably no other labor center in the country where the population is so diverse as at the anthracite mines. One company states that its average payroll last year was 12,782 men. Of the men employed in the course of the year, 6284 were Russians, 5284 Americans or naturalized citizens, 2141 Poles, 1165 Tyroleans, 805 Austrians, 751 Lithuanians, 599 Italians, 522 Slavs, 247 Hungarians and 100 Greeks.

Men of all nationalities are registering with their consuls for a possible return later, but many of them are over military age, many have already been naturalized and as there is a normal increase in population in the anthracite regions, many of the bread winners would be loath to desert their families.

On the other hand, many of the English employees of the mines are going home on account of their better facilities for getting there, and there are a number of miners among them. It takes three years to get a miner's certificate, according to the state laws of Pennsylvania, so these men are more difficult to replace than miners' laborers.

While there is a fair amount of hard coal in storage at present, most of it is of the steam sizes, and there is little domestic coal on hand, so those who are filling their bins now may not be altogether unwise.

In order to reduce the skin effect in conductors carrying heavy alternating currents of high frequency, it is customary to use a specially constructed cable having a hemp center. This type of cable is also required in many long distance transmission lines in order to increase the diameter sufficiently to prevent corona effects due to extreme potentials.

Editorials

Foreign Inquiry for a Large Tonnage

As evidence of the increasing activity in the export business, an inquiry has been received at this office for quotations on a tonnage of not less than 10,000 per month over a period of from one to three years. Quite favorable terms are offered, thus removing one of the most objectionable features the American operators have so far reported in this new business. On the other hand, it is noted that analyses must accompany all bids, which would indicate that the question of quality will be a ruling factor in the situation. Indeed, it is already generally accepted in all quarters that it will require the highest-grade coals we produce to meet the exacting requirements of this prospective foreign trade.

We would be pleased to have any coal company interested in securing a share of the prospective foreign business, communicate with us, in order that we may turn over to them any inquiries or information we receive relative to foreign opportunities. A representative of COAL AGE is now on the way to South America.

The Economic Resources of the United States

The present European hostilities have furnished a good opportunity for investigations, both public and private, for the purpose of ascertaining our own national resources. These inquiries have been conducted with a view to extending American foreign commerce, learning how far, or how nearly, we may supply at home many of the commodities heretofore imported from the Old World, and also with a view to discovering just how nearly we are or might become a self-sustaining country in time of national peril or calamity.

The Bureau of Foreign and Domestic Commerce is in daily receipt of many letters from American manufacturers and producers making inquiry regarding possible markets abroad for their surplus products, also as to the ability of the United States to supply the raw materials necessary to their industries. The investigations necessay to the intelligent reply to these letters have revealed the fact that in many instances materials imported from abroad are of a kind and nature already found in this country, the production of which is, however, at the present time in its infancy. This is particularly true of many chemical industries, the basic materials for which are now being partially utilized, whereas a few years ago, they were utterly wasted.

The position of the United States is peculiarly fortunate in its ability to supply the three primary requirements of man, in the shape of food, shelter and clothing. This is clearly demonstrated by an inspection of the figures showing the country's production of these commodities relative to that of the world.

There is no question but that the people of this cohntry may be fed from food-stuffs of home production. The United States has an area of somewhat over 3½ million sq. miles under climatic conditions which are highly varied. This area is equal or nearly equal in extent to the whole of Europe, which supports a population five times as great as that of this country.

Agricultural development in Amrica has not progressed to the degree of perfection attained by the people across the sea, and we may, therefore, legitimately expect that our production will incrase greatly in the future.

Even in our present status, this country produces over 2½ billion bushels of indian corn, which is approximately two-thirds of the world's supply. For the current year the wheat crop is estimated at 911,000,000 bushels, or about one-fifth of the world's yield. This country annually produces approximately 1,000,000,000 bushels of oats, or 25 per cent. of the world's crop, also something like 197,000,000 gal. of cottonseed oil, the food value of which as a substitute for olive oil is gradually becoming more recognized.

America possesses 15 per cent. of the world's cattle, or 59,000,000 head; this is twice the number raised in Argentina, and one-half as many as are maintained in India. We also have 50,000,000 sheep, 60,000,000 hogs and 24,000,000 horses. On the other hand, we import 2,500,000 tons of sugar, or approximately 1½ times the amount produced in continental United States and its island possessions.

So far as textiles are concerned, the United States produces over 14,000,000 bales of cotton annually, or one-half the world's supply, a little less than 300,000,000 lb. of wool per year, this being supplemented by approximately 238 million lb. of foreign wool and importations of woolen goods to the value of $34,000,000.

As regards mineral production, the position of the United States is unquestionably preëminent. We produce 40 per cent. of the world's coal, 238,000,000 barrels of petroleum, or ⅔ of the world's output, 57,000,000 tons of iron ore, out of the world's production of 132,000,000 tons; and, during 1912, nearly one-half of the world's copper came from American mines. The world's annual production of gold is valued at $466,000,000, and of this total output in 1912, the United States furnished approximately 20 per cent., being exceeded only by South Africa. Twenty-eight per cent. or thereabouts of the world's silver, and 30 per cent. of its lead are produced in this country.

In the value of its manufactures, the United States excels the world, but the product of its mills is almost entirely consumed at home. Of manufactures to the value of $21,000,000,000 produced in the United States in 1909, only about 5 per cent. found its way to other countries, the foreign markets for iron and steel, cotton goods, chemicals and many other industrial products, being held by various European nations.

The above figures indicate clearly the strong position which this country holds in regard to those factors of

national wealth which render a people self-sustaining. They may, to a certain extent, be summarized as follows: With 7 per cent. of the world's land area, we have 6 per cent. of its population; we produce 68 per cent. of the world's supply of corn, 20 per cent. of its wheat, 50 per cent. of its cotton, 10 per cent. of its sugar, 35 per cent. of its tobacco, 15 per cent. of its cattle, 40 per cent. of its coal, 63 per cent. of its petroleum products, 55 per cent. of its copper, 44 per cent. of its iron ore, 20 per cent. of its gold; and we have farm products annually to the value of $9,751,000,000, while our various industries annually produce commodities to the value of $20,672,000,000. Our imports for the fiscal year 1914 were $1,849,000,000, while our exports during the same period were $2,365,000,000. These are 9 and 12 per cent., respectively, of the world's total. We have approximately 259,000 miles of railroad, or 38 per cent. of the railway mileage of the globe, and our aggregate weath is figured at $140,000,000,000.

While actual figures of production in themselves mean little or nothing, it is when seen in percentages of the world's total that they become truly significant. We may justifiably believe from the above, that this country could, should the necessity therefor arise, produce all of the necessities of life required by its people, and not a few of the luxuries as well.

Electricity, an Economical Factor in Mining

The aim of every mine manager is to reduce costs. The ever-increasing burdens being placed on the coal industry by legislative action, and through the demands of labor, render it necessary for mining companies to adopt measures of economy wherever such action is possible.

There is more and more evidence coming to hand that shows the considerable saving resulting from the adoption of electricity for power purposes. On p. 454, this issue, attention is called to the economies effected by a Western company through substituting electricity for steam.

We have before us data from still another mine where the same plan was carried out. In this latter case the mining company installed a plant, the total cost of which was $106,000. By the adoption of the scheme, the colliery fuel consumption has been reduced more than 2 per cent. Twenty-five horses have been dispensed with underground, and there has been a great reduction in labor, due to the substitution of mechanical for animal haulage.

Plenty of current is available underground for further extensions in the way of haulage, coal cutting, lighting, etc. And referring to the matter of lighting stations underground, if electricity is not actually more economical, there is no doubt but that it is far more convenient and much safer.

The management of the plant in question represents to us that the saving resulting from the adoption of electricity amounts to 18½ per cent. when expressed as interest on the capital outlay.

In speaking of the initial cost of such installations, we have in mind a plant which was put in at a small mine where the company did not feel able to invest in a complete or elaborate equipment. The entire installation was effected by the colliery staff. Old iron and steel winding and haulage ropes were used instead of copper cables. The surplus power of three-ventilating fan engines, and the sawmill engine was employed, so that only the dynamos, lamps and small lengths of branch cables were required to be purchased. This installation is referred to, not for any real value it possessed, but simply to show how the engineer may adapt himself and successfully apply whatever simple means he may have at hand.

Given the necessary initiative, the mining experience of the purely practical order may have its compensations in that it often compels the engineer to look at science in the light of its real application, and to understand more thoroughly the limits to which one may go when conditions or circumstances are quite unfavorable.

Rescue Work

The important work of rescue after a serious mine accident, should be standardized as much as possible. Conditions, of course, differ, so that hard-and-fast rules cannot be laid down; however, there should be the broadest possible exchange of ideas and experiences, so as to perfect as far as possible an effective service.

Many mistakes have been made in recovering mines after accidents. Lives have been sacrificed unnecessarily. Some points gathered from recent experience may well be repeated and emphasized!

Every corps going underground, for the purpose of rescuing entombed miners, should carry, aside from the ordinary outfit, additional apparatus to be used as a "salvator." When men are found overcome by gas, a salvator should be fixed on each one, and he should be brought back to the rescue base. If a team comes across two men, one injured and the other uninjured, the latter should be brought out first, and on the second trip, the men should take in a stretcher and upon it convey the injured man to a place of safety.

The European practice of establishing a base where doctors, inspectors, colliery officials, ambulance men with stretchers, and all others following the team and who are not provided with apparatus must stop, is a good plan. At such a base the team leaves a canary and all their spare gear. Those without apparatus on coming up must not advance beyond this point.

If, on returning to the base, the rescue team finds the bird alive, they can take out their mouth piece to speak, but if the canary is dead, everyone will know that the gas has backed up, and all will proceed to the shaft bottom or the surface, where they can secure another bird.

These suggestions may not seem so consequential to many, but it is the neglect of small details that has so often caused disaster. We would be glad to have any of our readers add further precautionary measures, suggested by their own experience.

Oil from Coal

The nations of the world are turning more and more to the use of oil for burning under boilers on the smaller battleships. Coal operators need not be alarmed at this tendency to replace coal, for the supply of oil suitable for power purposes in the world today is hardly adequate to satisfy the present urgent demand. It is probable, therefore, that the application of a little sense and science to the subect on the part of the coal industry will bring about the manufacture of all the oil needed from those coal seams which readily yield such a product.

Extracts from a Superintendent's Diary

Occasionally seven-passenger touring cars and sometimes larger ones loaded to capacity with pleasure seekers pass through our camp. We are not exactly on a main highway, but we are near enough to one to be considered accessible by any whose curiosity suggests a visit to a miner's village.

Honk, honk, we hear them coming long before they arrive, and at the first intimation of their approach, the small children (we are always well supplied with children) grab up their marbles from the streets and make for the sidewalks. They have long since learned that automobilists have little sympathy for kids who play on streets. As they pass by the staring children they inquire the way to my office and immediately on arrival one of the party comes blustering in and condescends to introduce himself, and then without further preliminaries, suggests that the party which he has the honor to represent would like to make a trip underground.

Of course, these requests generally have to be denied, but I always take special pains to explain fully that we are compelled to have very strict rules governing such matters, and then I suggest that with sufficient advance notice it is possible sometimes to arrange such trips, notwithstanding the fact that the company management views them with increasing disfavor because of the risks which must be assumed by all parties concerned under the most favorable conditions.

Disappointed in the main adventure, they do not tarry long, but as they retrace their way through the camp, they feel called upon to converse with some of the children and even some of the grownups, if any chance across their path.

Afterward, by comparing notes, the ones interviewed are able to decide just what the outside world thinks of us.

The picture is always the same, it is the picture of the yellow journals; miners toiling in darkness from sunrise until sunset, earning tremendous wages which they never receive because of the coal barons, who despoil them just as they despoil the starving, freezing dwellers of the city tenements.

I find that similar opinions are held by the vast majority of people, who have no personal knowledge of the mining industry.

My oldest boy, who is away at college, is always in hot water because he lets his temper get the best of him whenever any of his associates inadvertently comment on some reporter's story about a mine strike, or a mine explosion, which reflects discredit upon the mine management.

I have just returned from a vacation trip, and, while traveling about, heard coal-mining men discussed a good deal in Pullman smoking compartments, because as it happened, a group of them were trying to get control of a large tract of coal land in the state through which we were passing.

Sometimes I put in a good word for the "barons," but at other times when every other member of the party expressed such hostile views and came out with them so impulsively, I quite lost my nerve and took out my resentment in biting fiercely on my cigar.

If it were not for the frequent strikes that disrupt and terrorize the industry, it would make little difference to the average mining man as to just what the world at large thought of him, but it is becoming more and more evident that during such times public opinion has much to do with the final outcome and we are incredibly handicapped by the public's willingness to judge us by previously formed opinions which are so unjust to us, but which so closely agree with the statements issued by the strike leaders at every opportunity.

Recent Legal Decisions

Reservation of Coal in Deed—When land is conveyed under a deed which reserves to the seller all coal underlying the land, excepting that reserved by him in a previous deed to a third person, and it appears that in fact there was no reservation of coal under such earlier deed, the purchaser takes no interest in the coal, for lack of any definite description of the quantity intended to be conveyed.—(West Virginia Supreme Court of Appeals, Cummings vs. Hamrick, 82 South eastern Reporter, 44.)

Liability Under Montana Coal-Mining Code—A completed tunnel in a coal mine, used by a miner as a passageway, is not a "working place" within the meaning of the requirements of the Montana Coal-Mining Code that miners must inspect and keep safe their working places; the duty to inspect such a tunnel devolving upon the company's foreman. A miner did not assume the risk of being injured through fall of overhanging loose rock in a tunnel, by reason of the fact that he made a visual examination of the place and found it to be apparently safe. A coal company and its superintendent and assistant foreman are jointly liable for their negligent failure to make proper inspection and repairs to secure the reasonable safety of employees, if injury results to one of the employees as a direct consequence of such failure. (Montana Supreme Court, McInnes vs. Republic Coal Co., 140 Pacific Reporter 235.)

Liability for Injury to Miner—A mining company cannot be held responsible for injury to a miner, caused by a blast in an adjacent entry breaking through the intervening wall or rib, on the theory that the company failed to furnish a reasonably safe place for work, if the condition existed by reason of the fact that the miner or his coemployee in the adjacent entry, or both of them, drove their headings unduly wide. "This did not constitute an unsafe place within the common-law doctrine of the master's duty in respect to furnishing his servant a safe place in which to do his appointed work, for the reason that the work in which intestate and his coemployee were engaged created the place itself and the defective condition of which plaintiff complained." Nor can recovery against the employer be sustained on the theory of negligence in failing to discover the unsafe condition, if the condition was created by the blast which caused the injury. (Alabama Supreme Court, Sloss-Sheffield Steel & Iron Co. vs. White, 65 Southern Reporter 999.)

Effect of Mining Contract—Defendant lent money to plaintiff to develop a coal mine, and agreed to purchase the entire output under a contract which contained this clause: "The prices named in this contract are based on the present Michigan mining rates of $1.01 per ton, and shall be increased or reduced on all sizes of coal as said mining rate may advance or decline, during the life of this contract." At the date of the contract an agreement between the coal operators and the Miners' Union fixed the prices paid by the operators for various kinds of work, but later a new agreement was made. The former agreement fixed the pick mining scale "for 30 in. of coal and upwards" at $1.01 per ton, and the later agreement increased this item to $1.06. Defendant construed this as increasing the price five cents per ton on all sizes of coal and made payment accordingly. Plaintiff claimed that the new agreement with the miners involved an increase of 5.26 per cent. in the cost of producing all coal, and brought suit to recover the amount remaining due from defendant on that basis. Held that the contract between plaintiff and defendant must be construed as fixing the rate for mining 30 in. coal as the basis for any increase or decrease in the contract price of the coal, irrespective of other items connected with the cost of mining. Hence, plaintiff is not entitled to recover. (Michigan Supreme Court, Caledonia Coal Co. vs. Consolidated Coal Co., 148 Northwestern Reporter 187.)

Sociological Department

First Aid Meet at Valley View Park

Keen but friendly rivalry marked the efforts of 16 first-aid teams to capture the Captain William J. May cup in the 9th annual field-day contest of the Pennsylvania Coal Co. and the Hillside Coal & Iron Co., held at Valley View Park, near Wilkes-Barre, on Saturday, Sept. 12.

Captain May is regarded as the father of first-aid contests in the anthracite field. Nine years ago he conceived the idea of bringing the various first-aid corps of the collieries under his jurisdiction together in friendly contests, and in order to incite interest and increase proficiency among the various teams, he donated a loving cup. To retain permanent possession of this trophy it is necessary for one team to be credited with three victories.

EWEN BREAKER TEAM, WINNER OF CAPTAIN MAY CUP

Left to right: Harry Skinner, Tony Polis, Joseph Vanderberg, Wm. Scott, Wm. C. Davies, captain.

MEN WHO TOOK PART IN INDIVIDUAL CONTEST

Left to right: John O'Malley, Del Burdick, Thos. E. Ross, winner, Alex Graham, Moses Ballentine, Wm. Garigan.

The 16 teams which gathered this year at Valley View Park came from the various divisions of the company, Mayfield, Dunmore, Avoca, Forest City, North and South Pittston being represented. Three problems were given each team to work out and the team scoring the highest general average was declared the winner.

The Ewen breaker team, known as the Ewen outside team, won the cup this year with an average of 98, having made a perfect score in two of the problems. The Old Forge breaker team of the Avoca district was second with a general average of 96 and the Mayfield colliery team was third with an average of 93⅓.

Aside from the general events there was an individual contest in which six men participated, these being selected from the different districts. Handsome prizes were offered for their solution of a single problem. A gold watch was offered the winner, a gold chain went to the second best, a pair of cuff links to the third, a scarf pin to the fourth, a safety razor to the fifth and an umbrella to the sixth.

Besides working out the single problem, each contestant in this event was taken before the judges and for a period of five minutes was quizzed along various lines of first-aid work. The success of the contestant depended as much on this mental examination as it did on the field work, and after much delay, Thomas Ross, representing the North Pittston district, was declared the winner, with an average of 95. John O'Malley, of Mayfield, was second, and Moses Ballentine, of Avoca, third.

The judges were highly complimentary of the work displayed in the individual contests and also spoke in flattering terms of the efforts of the various teams, one of the judges remarking that he had seen some exhibitions during the day which would challenge the very best efforts of a highly proficient doctor or surgeon.

Event No. 1 was for three men only. Problem: "Show two methods of performing artificial respiration, one with arms broken or burned. Show how to use control of arterial bleeding from all parts of body by the use of the triangle and roller bandages. Use of roller bandage optional." Time limit, 10 minutes.

Even No. 2 was for four men. Problem: "Wound extending from front of right ear to middle of top of head on a line with the ears; fracture of left lower jaw; wound of left groin, and upper front part of thigh. Bad sprain and constusion of right ankle with extensive swelling." Time limit 10 minutes.

The third event was for full teams. Problem: Fracture of middle of index finger of left hand. Fracture of middle upper right arm. Compound fracture at middle of left thigh. Both eyes injured by shot. In addition, the man is unable to use right leg. If asked to move his leg, it is seen that he is entirely helpless. Treat for this condition as you think best." Time limit, 15 minutes.

The judges awarded marks as follows to the 16 teams in the three events, the average of which decided the winner:

No. 5 Shaft, No. 6 Colliery Team and Subject

Erie Colliery Team, Mayfield District.

Team	District	Event No. 1	Event No. 2	Event No. 3	Aver.
Ewen Breaker.....	South Pittston	94	100	100	98
Old Forge Breaker..	Avoca	88	100	100	96
Erie Colliery.....	Mayfield	97	88	95	93⅓
No. 2 Shaft.....	Dunmore	92	95	90	92⅓
No. 9 Breaker.....	North Pittston	97	84	95	92
Coray Slope.....	Avoca	97	88	90	91⅔
No. 10 Shaft.....	North Pittston	89	100	85	91⅓
Forest City Breaker	Forest City	90	89	95	91⅓
No. 1 Head.....	North Pittston	98	90	85	91
Old Forge No. 1....	Avoca	94	86	90	90
No. 2 Shaft.....	South Pittston	95	88	87	90
Old Forge No. 2.....	Avoca	82	100	85	89
No. 5 Shaft.....	South Pittston	95	90	75	86⅔
No. 1 Shaft.....	Dunmore	89	81	90	86⅓
No. 7 Shaft.....	North Pittston	95	78	82	85
New County and Gray Slope.....	Forest City	88	89	75	84

In the Individual contest, there was one representative from each of the six districts and the problem solved was as follows: "Fracture of lower jaw both sides, and wound 3 in. long, running across back of neck. Wound on top of left shoulder and extending across chest to upper end of breast bone. Apply a dressing with triangle to a downward dislocation of right shoulder."

The result of this event follows:

Individual	District	Percentage
Thomas Ross.....	North Pittston	95
John O'Malley.....	Mayfield	94
Moses Ballentine.....	Avoca	92
Alex Graham.....	South Pittston	80
W. G. Garigan.....	Dunmore	79
Delbert Burdick.....	Forest City	77

Following the contests, Dr. H. J. Mahon distributed the prizes.

Dr. F. F. Arndt was director of the contests. The other officials follow: Judges: Drs. W. G. Fulton, F. J. Bishop, B. B. Wormser and W. A. Peck. Timekeeper, F. C. Weichel. Recorder, F. D. Conover. Managers, Frank H. Coughlin, W. P. Jennings, Davis Girvin and H. T. Mullen.

Members of the different teams which took part were as follows:

No. 2 shaft Mt. Dunmore—William Bulger, captain; Matthew Richards, Andrew Callo, William Tweksbury, John Wallace, John Kline, subject.

Shaft No. 5, No. 6 colliery, Inkerman—Peter Hollihan, captain; John Purcell, Patrick Flaherty, William Lynch, Bernard Corcoran, Richard English, subject.

Ewen Breaker, Port Griffith, outside—William Davis, captain; Joseph Banbenburg, Harry Skiner, Anthony Polis, William Scott, Daniel Mullery, subject.

Colliery No. 10, Hughestown—Michael Noone, captain; William Hart, Thomas Walsh, Harry Toole, Michael Quinn, Thomas Maloney, subject.

Mayfield colliery—John O'Malley, captain; James McDonald, George Mahalcki, George Kehoe, Clement Farrell; Jeremiah Gallagher, subject.

Shaft No. 1, at colliery No. 9, Hughestown—Edward Quinn, captain; George Heimarch, James Flynn, Frank Scheiber, Charles Lahey, Edward McCloskey, subject.

Outside No. 9 breaker, Hughestown—Thomas Ross, captain; John Miller, Louis Heal, Harold Herbert, Arch Eshelman; Max Melcher, subject.

Leadville shaft, North Pittston—Alexander Tait, captain; James Scott, Patrick Walsh, Martin McGarry, John Cooper; James Toner, subject.

Old Forge breaker—Moses Ballentine, captain; Michael Quinn, Thomas Cranston, Harry Newton, William Bennett; George Robinson, subject.

Shaft No. 2, Old Forge—Henry Odgar, captain; William Odgar, Edward Slattery, Edward Finley, Joseph Shively; Max Stack, subject.

Shaft No. 1, Old Forge—John Lewis, captain; Frank Joyce, John Joyce, William Garrett, Charles Sherrer, Oscar Stetler, subject.

Shaft No. 1, Dunmore—Julius Thomous, captain; Thomas White, John Merrick, John Sagan, John Lakas, John Lock, subject.

Corey Slope, Old Forge—Frank Young, captain; William Tigue, William Major, Charles Boose, Edward Harrison, Walter Goldworthy, subject.

Forest City colliery, outside—James Johnson, captain; Earl Pancaust, David Evans, George Holmes, John Stork, David Williams, subject.

Gray slope, Forest City—John Jones, captain; Walter Johnson, David Simonson, George Carpenter, Robert Davis, Joseph Swallon, subject.

South Pittston No. 4—Bernard McDowell, captain; Robert Shelby, Daniel Brennan, Ben Howard, John Owens, Fred Jenning, subject.

The Four Judges

Left to right: Doctors B. B. Wormser, F. J. Bishop, W. A. Peck, W. G. Fulton.

Discussion By Readers

Keeping Rooms on Sights

Letter No. 2—Referring to the inquiry by Mine Foreman, COAL AGE, Aug. 22, p. 317, in regard to keeping rooms on sight, permit me to say that the only satisfactory system that I have ever seen used is to run a whitewashed line up the room on sight, as there suggested.

It is very little work to put in these whitewashed lines and extend them as the room advances. If any falls of rock or timber occur, at least a part of the line will be left remaining so that it can be extended when required. Where tracks are laid up the rooms, I consider that it is preferable to put the whitewashed lines over one of the rails. This rail should be at a fixed distance from the rib, depending somewhat on the system of mining, so that the miner will know that the rail which comes under the whitewashed line is such a distance from his rib. By using this system the rooms can be "kept on sight" and as the foreman watches the width of the rooms the pillars can be kept within a foot of their standard width.

In establishing the whitewashed line, for the first time, the engineers will set the sights the same as for ordinary sight driving; that is to say, by putting two plugs in the roof about three feet apart. In extending the whitewashed line, one man will go to the face with one end of the chalk line, while another man stands behind the sights and holds the other end of the line. The light in the face shows when the line has the proper course. The line should then be tightened and snapped against the roof. This leaves a faint mark, which should immediately be run over with a whitewash brush.

In extending the line again, all that is necessary to be done is to secure two points on the whitewashed line and use the chalk line, drawing it through these points and snapping it against the roof, as in the first instance. If this method is followed carefully the rooms and pillars will be kept a uniform width throughout, and it will only take a short time to educate the miner in this system.

J. F. MENZIES, Manager,
Carbon Hill Coal Co.

Carbonado, Wash.

Letter No. 3—I was much interested in the inquiry in reference to driving rooms on sights, COAL AGE, Aug. 22, p. 317. Having had some experience along that line myself, I wish to say that we found it difficult to keep sights when these were placed in the roof. For this reason, we decided to set permanent stringers across the mouth of each room, about 4 ft. apart. When this was done, we got the engineer to put the room sights on these stringers and have had no trouble since from the sights being lost.

In our mine, the butt entries run N 66° E, and the rooms are turned off these entries at 90 deg. As the face cleats in the coal run nearly north and south, this makes a long corner at the face of the rooms. The sight line is kept about 2½ ft. from the straight rib.

I make a practice of sighting to the face of every working place once each week. If the face in any room is found to be off line, it is stopped at once, and the miner is ordered to take a skip off the rib sufficient to allow of the free passage of the sight line. This practice soon cures a careless miner, because the stopping of the face, cuts off his turn and he is unable to load the same number of cars, which considerably reduces his earnings.

Permit me to suggest that if Mine Foreman, from Kentucky, would provide himself and his assistants with a set of plumb bobs and check up the rooms in the mine once or twice a week, imposing a suitable penalty on those miners who disregard the sights, I believe he would have no further trouble with the holing through of one room into another.

D. W. SEIGHMAN, Fireboss,
McKeefrey C. & C. Co.

Martin, Penn.

Problems in Rescue Apparatus

Letter No. 3—If the quotations of Mr. Elmer, COAL AGE, Aug. 22, p. 314, from an "eminent physiologist, in England," are to be taken as correct, it would mean that we will have to revise very considerably our ideas relative to rescue apparatus. These statements, also, seem to contradict what we have been taught very generally, in respect to the relative amounts of oxygen consumed and carbon dioxide produced in the act of breathing.

Authorities state that atmospheric air consists, by volume, of 79.1 parts nitrogen and 20.9 parts oxygen, with very small percentages of carbon dioxide. Numerous high authorities also state that the average of analyses of air expired from the lungs shows nitrogen, 79 parts; oxygen, 15.5 to 17 parts; and carbon dioxide 4 to 5.5 parts. I find it difficult to harmonize these generally accepted data, with the statements made by correspondent on p. 314. He states:

> The amount of carbonic acid (carbon dioxide) breathed out is the same as the amount of oxygen taken in when a man is oxidizing carbohydrate food, etc.

Again he states:

> If a man is oxidizing fat or protein, which is the chief constituent of meat, he will not expire quite as much carbonic acid (carbon dioxide) as he inspires oxygen. . . . At the most, less than one-third of the oxygen would be turned into water, etc.

Referring to the first of these statements, I drew attention, in a previous letter, COAL AGE, Vol. 5, p. 1062, that of the 120 liters per hr., supplied to the wearer of an apparatus, apparently only 50 liters are consumed in the production of carbon dioxide, the same volume of which is absorbed by the apparatus; and it was explained there, in answer to my inquiry, that the remaining 70 liters of oxygen supplied per hour combined with the hydrogen of numerous hydrocarbons present in the body, to produce water, much of which, as we know, drains from the apparatus. Certainly, this proves that more

oxygen is inhaled than carbon dioxide expired, in the act of breathing. The second statement of correspondent, also, bears out this conclusion.

It is natural to believe, from these data, that, while a portion of the oxygen inhaled is converted into carbon dioxide, another portion goes to form water, and still a considerable portion is exhaled unchanged.

Nanaimo, B. C., Canada.

The Reverse or Counter-Current Theory

Since writing my last letter (Coal Age, Sept. 5, p. 398) in reply to an editorial reference to this subject, I have received my copy of Coal Age for Aug. 22, and read with interest the article of Samuel Dean, p. 294. I notice that Mr. Dean refers to Mr. Verner's theory as the "Counter-Current Theory," and I desire to offer a few criticisms of his statements and conclusions.

In the synopsis, at the head of this article, it would have been well if it had been stated which of John Verner's conclusions had been "accepted" by the British Experimental Station. This would have given point to the argument and have made the article more specific in regard to the application of this theory to the solution of mine explosions. One is left wholly in the dark, however, in regard to what particular points or phases of the theory were regarded as acceptable by the British experimenters.

Again, it may be assumed from Mr. Dean's article that he attempts therein to prove that "there is an inrush of air, as well as an outrush, probably throughout the duration of all explosive phenomena." I have quoted this sweeping assertion from the synopsis at the head of the article. Had the word "all" been omitted, the statement might have been passed by without comment, although it must be admitted that the word "probably" somewhat modifies the assertion. The statement covering, as it does, *all* the phenomena attending an explosion is quite too broad for general acceptation.

Mr. Dean begins his argument abruptly by stating his conclusion that the experiment made for him by Doctor Wheeler, at the Eskmeals Testing Station, proved that the counter-current theory was quite correct. While some may agree with him in this view, to a certain extent, many will take exception to his conclusions, after considering the conditions surrounding the experiment.

The testing gallery used for this purpose was 39 in. in diameter and 400 ft. long and closed at one end. A cannon was placed 50 ft. from the closed end, charged with 1½ lb. of black powder and stemmed with 8 in. of dry clay. A mixture consisting of 70 per cent. coal dust and 30 per cent. incombustible fuller's earth was strewn along the gallery, a half-pound of dust being used per lineal foot. This dust extended from the cannon to within 20 ft. of the mouth of the gallery, or, say a distance of about 350 ft.

Anyone familiar with coal mining can judge how closely the arrangement in this experiment reproduced the actual conditions existing in a coal mine. In the first place, there was no current of air or ventilation in the tube. Again, there was a dead space of 50 ft. behind the cannon, and, as a result, when the cannon was discharged, the initial velocity of the flame caused an outward blast of dust; but, as soon as the air space behind the cannon was rendered partly vacuous by the outward rush of the blast from the cannon, there was naturally a counteraction that caused an inrush of air, bringing a fresh supply of oxygen into the tube. This gave rise to the first pulsation.

It is not so certain what caused the other pulsations, though it is not improbable that they show the ignition and explosion of more dust, following the first inrush of fresh air. It must be quite clear to any studious mind that there was not sufficient air in the tube for the complete combustion of the dust, which fact caused the flame to die out before reaching the mouth of the tube, leaving much dust that would be available for a second explosion of equal or even greater force than the blast from the cannon.

In my opinion, it is exceedingly improbable that the same result would have been obtained had the cannon been placed in the dead end of the tube. The old saying that "nature abhors a vacuum" is clearly exemplified by the inrush of the air following each blast.

Turning now from the Eskmeals experiments made for Mr. Dean, to those made at Altofts, in the larger and longer gallery, it is interesting to note that the interval between each of the photographs taken, at that time, was about $^1/_{22}$ of a second. These photographs are reproduced on plate 5 of the report of the Committee on British Coal-Dust Experiments, and will prove both interesting and instructive, in this connection. The total time occupied by the flame in traversing the tube was estimated to have been $^1/_5$ of a second; and it was stated that the subsequent combustion occupied about a second more.

It is worthy of note that in not a single one of these pictures is there any evidence of a reverse or counter-current. In my opinion, this is wholly explained from the fact that the conditions in the Altofts experiment were practically the same as those existing in the mine. In the Altofts experiment there was a ventilating current passing through the tube, corresponding to the air current in mine airways, which was not the case in the Eskmeals experiment. I believe that the ventilating current made it impossible for a reverse current to be set up, because of the sufficiency of the supply of oxygen for the combustion of the dust. The commencement of the vacuum or condensation stage of every explosion is clearly shown in Fig. 24, p. 30, of the British report to which I have referred.

The experiment made for Mr. Dean at Eskmeals would seem to support the theory of Donald Stuart; but the experiment to which I have referred at Altofts goes a long way toward proving its fallacy. The fact observed in every colliery explosion, that the flame of the explosion is mainly confined to the top or upper portion of the roadways, is clearly demonstrated by facts, since men are seldom burned below the knees and often not below the waist. The force of the explosion, however, is distributed over the whole sectional area of the roadway. In some mines, this may be attributed to the extra fineness of the coal dust lodged on the timbering; or, in gaseous mines, to the presence of small percentages of gas in the air close to the roof of the roadway.

James Ashworth,
Mining Engineer.

Vancouver, B. C., Canada.

Heating of Coal

In reading the editorial entitled The Storage Problem, COAL AGE, Aug. 22, p. 306, my attention was attracted to the following paragraph:

> In fact, that oxidation is not the important cause of heating is evidenced by the fact that coal is slow to become heated; yet all the deterioration in the earlier stages is due to oxidation. Later the coal becomes dried out in the sun and when it is moistened the heat of hydration probably causes it to fire, though other causes are possible.

I am unable to agree with some of these statements. In the first place, the deterioration, in the earlier stages of coal storage is not, by any means, due entirely to oxidation. Much of the deterioration observed in the coal, in respect to its calorific power, is undoubtedly due to the loss of heat units, which it experiences by the liberation of its methane. The deterioration in the heat value of the coal, from this cause, has been recently confirmed by the experiments of Parr and Baker, at the Experiment Station of the University of Illinois (Bulletin No. 32, 1909).

While it is true that oxidation is continually taking place in the coal, during the period of storage, this oxidation is not accompanied by a proportionate evolution of carbon dioxide, which points to the fact as probable that most of the oxygen absorbed by the coal enters into chemical combination with the resinous bodies contained therein; and, if this be true, there is a less production of heat in this combination than would result in the production of carbon dioxide by other forms of chemical reactions.

In the second place, since coal is a very poor conductor of heat, the sun's rays have little effect falling on the surface of the coal to impart heat to its mass. It is a significant fact that heating in coal piles never starts nearer the surface of the pile than 3 or 4 ft. For this reason, the drying of the coal stored in piles must be ascribed to other causes than the heat of the sun. As a matter of fact, continued observations on coal piles show that the coal on the interior of the pile is always damp and, consequently, can never become dehydrated so as to afford opportunity for further hydration to occur in the pile.

It is more probable that the heating, in the later stages of coal storage, may be ascribed to the absorption of oxygen, as carbon dioxide is then liberated in larger measure, accompanied by the evolution of much heat. It has been definitely proven that the production of carbon dioxide increases as the temperature rises, until the action eventually becomes autogenous or self-sustaining and the coal catches fire.

J. B. DE HART.

Coleman, Alta., Canada.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

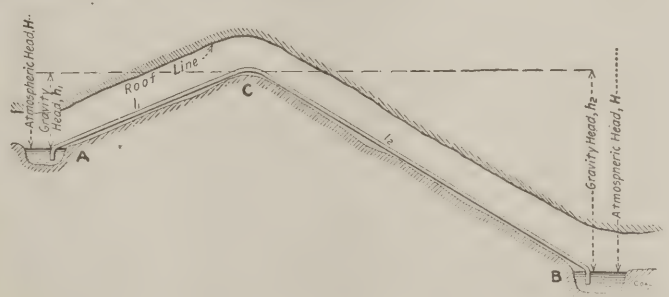
Water Feeders—Water, like gas, not only permeates the softer and more porous rocks, but completely fills the interfoliations of the strata and all cracks and crevices, which form natural channels or underground waterways by which the water flows or drains into the mine. A fault or dislocation of the strata is almost invariably a natural channel that offers little resistance to the flow of water or gas.

A copious flow of water from a fault or from a particularly wet stratum in the rocks or from a crevice in the formations is termed a "feeder." The flow of water from such feeders is variable, being generally greater in wet than in dry seasons of the year. The flow from a water feeder may also be increased by the disturbance of the roof stratum, owing to the rapid development of the mine, particularly when an impervious roof is overlaid with watery strata, or the mine workings are extended beneath rivers, lakes or other bodies of water on the surface.

DITCHING

All mine roads and most passageways should be ditched on one or both sides of the entry or passage, in order to provide suitably for the natural drainage of the roadbed or floor. The lack of proper ditching of mine roads is the cause of much trouble and expense in the maintenance of the tracks, and, in many cases, is the unsuspected cause of the reduction in the daily output of a mine.

It may not, however, be always advisable to ditch a roadway laid on a hard **clay bottom.** The track should then be ballasted with rock or cinders. The disturbing of a clay bottom in a mine passageway often starts trouble from a continued and increasing tendency of the floor to heave. This tendency is more pronounced in some mines and localities than in others. Experience is always the best guide in practice.



The flow of water in ditches is treated elsewhere; but this is unimportant in its relation to mine drainage, the matter of chief concern in mining work being to dig the ditches and to keep them clear of obstructions that would impede the flow of the water through them.

SIPHONING

The application of the principle of the siphon to mine drainage is of the greatest importance in respect to economy of operation. While ditching is an effective means of drainage in practically level seams or on roads of uniform grade, the process is not practicable when hills and swamps succeed one another in the development of the mine. This necessity for deep ditching is obvious when crossing a slight rise or "roll" in the seam; but the expense, which is often prohibitive, is avoided (when the fall is greater than the rise), by the use of a siphon or pipe line laid over the rise. In this case, it is necessary to collect the water in a sump or basin provided for the purpose, beyond the rise, which will enable the complete submergence of the mouth of the pipe in this basin, this being important in order to prevent air from entering the pipe.

The Coal Age Pocket Book

Principle of the Siphon—The action of the siphon depends on the difference in weight between two columns of water that would otherwise be in equilibrium. The two water columns are contained in the long and short legs, respectively, of a bent pipe, as illustrated in the accompanying figure, which shows a siphon pipe laid in a mine entry and connecting an upper basin A with a lower basin B, the two basins being separated by a rise of gronnd C that prevents the natural flow of water from A into B. The pipe being air-tight, the greater weight of water in the long leg CB overbalances the lesser weight in the short leg AC, and the water flows from A to B by gravity.

IDEAL SIPHON PIPE LINE IN MINE

Conditions and Requirements—It is of the utmost importance for the successful working of a siphon, that all the pipe joints shall be air-tight and that the ends of the pipe should both be submerged to such a depth below the surface of the water, in each basin, as to prevent the entrance of air to the pipe. The submergence required is naturally greater at the intake than at the discharge end of the pipe, owing to the flow of water, in the one case assisting and in the other opposing the entrance of air.

Effective Head of a Siphon—As indicated in the figure, the atmospheric pressure or head (H) is the same at each end of the pipe. The gravity head (h_1) or the vertical rise of the intake end is always less than the gravity head (h_2), which is the vertical fall of the discharge end. The former opposes, while the latter assists the flow of water in the siphon. These gravity heads are often spoken of as the **"suction head"** (h_1) and the **discharge head** (h_2), respectively. Since the atmospheric head (H) is the same at each end of the pipe, this may be disregarded when considering the pipe as a whole; and the effective head of the siphon is therefore the difference between the gravity heads (h_2—h_1).

Inquiries of General Interest

Drawbar Pull on Incline

I would like to ask what will be the drawbar pull, in hauling a loaded trip of 100 cars up a 4-per-cent. grade, under ordinary mining conditions. Each car weighs 1550 lb., and carries 1½ tons (3000 lb.) of coal. Also, what should be the size of the connecting links and of the rope to haul this load, under these conditions?

CHARTER SUBSCRIBER.

Heilwood, Penn.

The weight of the loaded trip, in this case, is

$$L = 100\ (1550 + 3000) = 455{,}000\ lb.$$

On small inclinations, say on grades of less than 10 per cent., the weight of the trip may be taken as the normal pressure of the load on the incline, in which case the coefficient of rolling friction, that in general mining practice may be assumed as $f = 0.025$, is added to the percentage of grade expressed as a decimal and the sum multiplied by the weight of the loaded trip, to obtain the drawbar pull; thus,

$P = 455{,}000\ (0.04 + 0.025) = 39{,}575$, say 30,000 *lb.*

Then, taking the drawbar pull as 30,000 lb. or 15 tons, the diameter (d) of round Swede iron, for an open link, may be calculated thus,

$$d = \sqrt{\frac{P}{6}} = \sqrt{\frac{15}{6}} = \sqrt{2.5} = 1.58\ in.$$

This formula assumes an average strength of Swede iron of 60,000 lb. per sq.in., and allows a factor of safety of about 7.5, for a steady pull; or somewhat less than 4, allowing for shock.

In order to determine the size of rope required to haul this trip, it is generally necessary to know the length of the incline, as the load on the rope is increased by its own weight and friction on the incline. But, in this case, the additional load due to the weight and friction of the rope, has been more than covered by taking the load as 30,000 lb. For example, assuming for trial that the rope weighs 2 lb. per lineal foot and the incline is 1000 ft. long, the total weight of the rope would be $2 \times 1000 = 2000$ lb., which would make the total load resting on the incline 455,000 + 2000 = 457,000 lb.; and the load on the rope, at the top of the incline, is then $457{,}000 \times 0.065 = 29{,}705$ lb.

Wire-rope tables give the breaking load of a 6-strand, 7-wire, cast-steel haulage rope 1 in. in diameter, as 37 tons. Calling the safe working load L, in tons, and the factor of safety f, the breaking load is fL; and since the breaking load of a rope is proportional to the square of its diameter d,

$$d^2 : 1^2 :: fL : 37$$

and

$$d = \sqrt{\frac{fL}{37}}$$

The rope constants for 7-wire haulage ropes are as follows: Swede iron, 16; cast steel, 32; extra strong cast steel, 37; plow steel, 42. The constants for 19-wire hoisting ropes of the same grades are 17, 34, 39 and 44, respectively.

Therefore, taking the total load on the rope as 30,000 lb., and assuming a factor of safety, in this case, of 5, the diameter of a 6-strand, 7-wire haulage rope required for this haulage is

$$d = \sqrt{\frac{fL}{37}} = \sqrt{\frac{5 \times 15}{37}} = \sqrt{2.03} = 1.42,\ say\ 1.5\ in.$$

Anemometer Readings

I would very much appreciate an answer, through the columns of COAL AGE, to the following question:

What causes an anemometer to revolve faster when the dial is facing the air current, than when the air strikes the back of the instrument? When the dial faces the current, the instrument registers 1000 ft. per min., and when the back of the instrument is toward the air current, the registry is only 900 ft. per min.

D. W. SEIGHMAN, Fireboss,
McKeefrey C. & C. Co.

Martin, Penn.

In the use of the anemometer, in practice, it should be held at arm's length toward the wind, and in such position that the air strikes the back of the instrument. No obstruction is then offered to the air before it reaches the blades. It is important to hold the instrument so that the blades revolve in a plane normal to the air.

Every precaution must be taken to avoid the disturbance and deflection of the air before it strikes the instrument. To do this, the observer should face the side of the entry, so that his body will offer the least resistance to the air current. Holding the instrument, as stated, at arm's length toward the wind, the air striking its back, and holding his watch in the other hand, the observer touches the spring that throws the dial hand into gear, again releasing the dial, at the end of the time of observation, one or more minutes.

There are several things that may cause the disturbance and deflection of the air current before it reaches the instrument. In the first place, the body of the observer holding the instrument interferes seriously with the air travel, disturbing and deflecting the air before it reaches the instrument. However, when the face of the dial is toward the air, a still greater effect is produced by the outward radial deflection of the air striking this face. The dial deflects the air outward, radially, thereby increasing the pressure on the ends of the blades, thus giving to the vane a greater speed and producing a higher reading than would otherwise be registered.

This same question was answered some time ago in COAL AGE, Vol. 4, p. 871; but, owing to its importance, we are glad to explain the difficulty again. An instructive article in regard to the use of the anemometer will also be found, in the same volume, p. 655.

Examination Questions

Miscellaneous Questions

(Answered by request)

Ques.—What is meant by permissible explosives, and why are they termed thus?

Ans.—A permissible explosive, as defined by the Federal Bureau of Mines (Miner's Circular No. 6, p. 8), is any explosive similar in all respects to the sample that passed certain tests made by the U. S. Bureau of Mines and when used in accordance with the conditions prescribed by that bureau. The conditions and use prescribed by the Bureau are as follows:

1. That the explosive shall be, in all respects, similar to the sample submitted for test.

2. That the detonator used to explode the charge shall consist by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate, or their equivalents.

3. That the explosive, if frozen, shall be thoroughly thawed in a safe and suitable manner, before use.

4. That a charge shall be used not to exceed 1½ lb. (680 grams), which shall be properly tamped with clay or other noncombustible stemming.

Ques.—What are the advantages and disadvantages of the longwall retreating system of mining coal?

Ans.—The longwall retreating system of mining permits the relatively safe extraction of the coal in a seam overlaid with bad roof, or in seams of exceptional thickness or lying at a great depth below the surface. The system also possesses the advantage of reducing the expense for maintaining roadways in the mine, because these are all driven in solid coal. Also, less timber is required than in the advancing system.

The retreating system of longwall has the disadvantage of yielding slower returns on the capital invested, although this is partially offset by the reduced cost of production that results in most cases. Mining is generally safer in the retreating system than in the advancing system of longwall.

Ques.—What is the declination of the magnetic needle, in surveying, for Montana?

Ans.—The declination of the magnetic needle varies from 15 deg. E., in the southeast corner of the state, to about 22 deg. E., in the northwest corner. For central Montana, the present declination is about 19 deg. E.

Ques.—Is there any rule for determining the slant of timbers in pitching seams? Say, in a seam pitching 30 deg., at what slant should a timber be set?

Ans.—To withstand the roof pressure in a pitching seam, timbers should be set normal in the seam or perpendicular to the roof and floor; but, owing to the sliding movement of the roof down the pitch when the coal is extracted, all post timbers in pitching seams are "underset" or inclined slightly up the pitch, the amount varying with the inclination and thickness of the seam and depending also on conditions in the seam that affect the slipping tendency of the roof. No rule can be given but the underset of a post must be guided by experience, in any given locality.

Ques. 47—For what purpose is the air exhausted from the bulb of an incandescent lamp?

Ans.—The exhaustion of the air from the bulb of the lamp prevents the oxidation and destruction of the filament.

Ques.—How would you proceed to clear a shaft that is filled nearly to the top with carbonic acid gas?

Ans.—Assuming the shaft in question is being sunk, much of the gas may be bailed out with large buckets. This, however, is a slow process, and where the shaft generates large quantities of this gas, it is advisable to install a powerful blower that will exhaust the gas from the bottom of the shaft. The method sometimes employed, of pouring several barrels of water into the shaft, can only be used with success in a shallow shaft, and possesses the disadvantage that the water must be bailed out again. In sinking, under these conditions, a shaft should be equipped with air tubes and a suitable blower arranged to exhaust the air and gas.

Ques.—If 20,000 cu.ft. of air is passing per minute through a circular airway, 10 ft. in diameter, how many cubic feet per minute will the same pressure pass through an airway of the same length and 6 ft. in diameter, other conditions being the same?

Ans.—For circular airways of equal length and for the same pressure per square foot, the quantity of air circulated will vary as the square root of the fifth power of the diameter of the airway. In other words, under the given conditions, the quantity ratio is equal to the square root of the fifth power of the diameter ratio. Hence, in this case, calling the required quantity of air x,

$$\frac{x}{20{,}000} \sqrt{\left(\frac{6}{10}\right)^5} = \sqrt{0.6^5} = \sqrt{0.07776} = 0.2788+$$

$$x = 20{,}000 \times 0.2788 = 5576 \text{ cu.ft. per min.}$$

Ques.—An airway, 7000 ft. long and 6x8 ft. in section, is passing 20,000 cu.ft. of air per min. under a given pressure. What will be the sectional dimensions of this airway when enlarged in the same rectangular form, so as to pass 60,000 cu.ft. per min., under the same pressure?

Ans.—If enlarged in the same rectangular form, the cross-section of the enlarged airway will be similar to that of the original airway. For similar airways and for the same pressure producing circulation, like dimensions of the cross-section will vary as the fifth root of the square of the quantity of air in circulation. In other words, the ratio of change, for either the height or the width of the airway, will be equal to the fifth root of the square of the quantity ratio, which is, in this case,

$$\sqrt[5]{\left(\frac{60{,}000}{20{,}000}\right)^2} = \sqrt[5]{3^2} = \sqrt[5]{9} = 1.55$$

Therefore, the width of the enlarged airway will be $8 \times 1.55 = 12.4$ ft.; and the height $6 \times 1.55 = 9.3$ ft., making the required section of the enlarged airway 9.3 $\times$ 12.4 ft., in order to pass 60,000 cu.ft. of air per min., under the original pressure.

Coal and Coke News

Harrisburg, Penn.

Preparations are being made at Philadelphia harbor to ship 100,000 tons of coal to Greece, consigned to foreign buyers. Part of this order, which it is understood was secured by the Consolidation Coal Co., and the Pocahontas Fuel Co., will be filled from Virginia coal mines. In addition to the large sale of coal to Greece, it was reported, on Sept. 12, that J. H. Weaver & Co., of Philadelphia, had made a contract with the Navy Department at Washington for 200,000 tons of coal, mined exclusively in Pennsylvania, which will be shipped immediately from the Philadlephia port for use of American war vessels in the Mediterranean and Asiatic squadrons.

Berwind-White Coal Mining Co. and other big bituminous coal-producing operators, it is also understood, are receiving 'queries" from foreign sources. These shipments of coal are regarded by operators only as preliminary to the enormous possibilities for the port of Philadelphia in the coal export trade that has been brought on by the European conflict.

Other shipments are already moving from Philadelphia on actual foreign orders, and operators have announced at the mines that concerns are shipping by the hundreds of tons to Brazil, Argentine and other South American countries. These countries, before the war, bought annually $55,000,000 of a total purchase of $60,000,000 a year from England. Now they are turning to the United States, and the big coal operators are wondering whether they can hold the trade when peace is restored.

In recent years, very little coal for the navy has gone through the Philadelphia port, as but little Pennsylvania coal was taken. The contract awarded to J. H. Weaver & Co. clearly shows that Pennsylvania coal is of the standard required by the Navy Department. Operators throughout the state are expressing considerable glee over the recognition by the government of the merits of the Pennsylvania fuel. All of this order, it is understood, will be supplied from mines in Cambria County, and it is the belief among operators that the state has reëstablished permanent relations with the Navy Department.

During the last week, six vessels were chartered to take Pennsylvania coal to South American ports and three to Piereaus, Greece. The European source of supply has been cut off, and recent dispatches from London indicate that coal is not being exported from Wales except in small quantities to Italy. These conditions, it is pointed out, give Pennsylvania and the other coal-producing states of the Atlantic coast an opportunity to not only meet this new South American demand, but at the same time to establish for the producers and dealers of Pennsylvania a permanent market for coal in other parts of the world.

Because of the fact that the English, French and Germans in South America have the system of interlocking directorates to a most effective degree, it was authoritatively pointed out that this might make it difficult for American companies to hold the coal trade when peace reigns again. The same set of men that are directors of the companies in South America needing the coal are directors of the mines abroad producing the fuel and directors of the steamship companies delivering it. But coal men of this country see no reason why they should not enter the South American field and retain a large part of it. They point to statistics which they say inspired them to make the fight. Of the $25,000,000 worth of coal imported into Argentina in 1912, $23,500,000 worth was from England, $381,000 worth from Germany and $783,000 worth from this country. In Brazil, the value of the coal imports for the same year was $18,500,000, of which $15,500,000 was from England and $2,700,000 from the United States. In Uruguay, where the coal imports amount to about $3,000,000, the conditions are about the same. In Chili, the coal imports in 1912 were $11,000,000 in value, of which $7,000,000 was from England, $278,000 from Germany, $503,000 from this country and the rest from Australia.

The United States now turns out from her mines practically 40 per cent. of the coal output of the world. American coal, it is pointed out, holds high rank, that of certain of the greater mining sections lying within easy reach of tidewater being considered equal to Cardiff coal for steaming purposes, and generally acceptable wherever thoroughly and impartially tested. The fact that the steamships plying between Europe and the United States bought last year approximately $25,000,000 worth of American coal for their own use on the ocean is an evidence that it compared favorably, at least, with the fuels of Europe.

Pennsylvania's Mineral Production

The reports of the mineral production made to Richard H. Hice, state geologist of Pennsylvania, show the production of 1913 was by far the greatest of record, exceeding the previous highest record by over $55,000,000.

In 1911, the total value of the mineral production of Pennsylvania ,excluding pig iron, coke and derived products, was $414,426,962. In 1912, this total value was $445,790,022, and in 1913 the total rose to $500,923,357, or almost one-fourth of the entire output of the United States.

Since the first records of the mineral production of the United States were made, Pennsylvania has stood at the top of the list and occupies a unique position in that respect, inasmuch as it greatly surpasses any other state. This production is almost equal to the combined output of Illinois, West Virginia, Ohio and California, the four next states as regards the value of their mineral wealth.

While Pennsylvania holds this unique position as a mineral producer on account of the enormous value of its coal output, which, in 1913, was $388,220,933, yet it must not be overlooked that if the entire coal output of the United States is disregarded, Pennsylvania is still the ranking state, exceeding California, which would be the second.

The anthracite and bituminous coal produced in 1913 was almost equal in value to the entire mineral production of West Virginia, Illinois and Ohio, the second, third and fourth producing states. The production of anthracite coal in 1913 was the highest on record, 81,818,680 long tons, exceeding the previous high-record mark by slightly more than 1,000,000 tons. The value at the mines was $195,181,127, exceeding the value of the production of 1912 by almost $17,500,000, and that of 1911 by $20,000,000.

The production of bituminous coal rose to an average of 700,000 tons for each day the mines were in operation. The total value of this production was $193,069,806, or $1.11 per net ton, the highest average price received for bituminous coal in the state for 30 years.

The total quantity of petroleum produced in Pennsylvania in 1913 was 7,927,137 barrels. The value of this oil was $19,716,148. There was a marked increase in the value of natural gas produced, the total value for the year being $21,695,845. The production of gasoline from natural gas is quite a new business, yet in 1913 gasoline was produced, which otherwise would have been lost, to the value of $405,186.

PENNSYLVANIA

Anthracite

Minersville—As a result of a brisk demand for anthracite coal, caused by the European war and the early cool weather, the Lehigh Valley Coal Co., on Sept. 11, ordered the immediate resumption of work at the Blackwood colliery. Work was suspended at that colliery in the middle of the summer, and it was not expected that the condition of the coal trade would warrant resumption of work until the middle of winter. Blackwood colliery produces a particularly good grade of anthracite. Six hundred men and boys will be given work.

Tamaqua—Orders were issued on Sept. 11, by the Lehigh Coal & Navigation Co., calling for resumption of the large washery at Hauto, Sept. 16. Coaldale washery will resume Oct. 1, and others throughout the Panther Creek Valley as soon as repairs can be made.

Scranton—Gas from a broken main of the Scranton Gas & Water Co., on Prospect Ave., recently leaked through the crevices in the ground and made its way into the workings of the National colliery of the Lackawanna Coal Co. This was discovered when miners with naked lights entered the vicinity and caused the gas to ignite. The break in the main evidently occurred in the morning after the fire boss had made his rounds.

Judge E. C. Newcomb recently issued an order restraining the Clearview Coal Co. from mining within 100 ft. of the line

of the No. 40 school building in North Scranton, so that the property may be saved.

Throop—The button strike of the Pancoast colliery has been called off. This affected approximately 1500 men there employed. The strike was caused by 17 mine workers at the Pancoast colliery who got in arrears as members of the union and were suspended under the rules. The rest of the workers refused to work with the 17 delinquents.

Bituminous

Kittanning—The Queenstown Coal Co., which has been engaged in opening its mines near Kittanning, is now ready to begin the shipment of coal.

Irwin—Notices have been received here recently by the unnaturalized Austrians, commanding them to return home for military duty, since their services are needed by their country. It is said that the Austrian government has the correct address of every reservist in this country. The men are given notice where they shall report and what regiment to join. Those in this immediate vicinity are instructed to go to a point near Lemberg.

Connellsville—The present rate of coke production is approximately 267,000 tons per week. Divided between the furnace and merchant interests the proportion being approximately 169,000 and 98,000 tons, respectively. No new transactions in contract furnace coke have been reported, and practically no business of this sort is in sight. On the other hand, with a single exception, no furnaces are likely to go out of blast in the near future.

Thomas D. Williams, mine inspector of the Sixth Bituminous District, recently caused the arrest of a superintendent who failed to provide two passageways from the operation under his charge, as provided by law. He has also brought action against two foremen who neglected to provide shelter spaces at 15-ft. intervals along haulageways. Furthermore he has prosecuted two miners who were accused of substituting open lights for the safety lamps supplied to them by the company.

Windber—First-Aid Instructor Allan S. Snyder of the Berwind-White Coal Mining Co., has announced a first-aid meeting will be held early in October by teams composed of the employes of that company. There is much rivalry between the miners of the various operations of this company in this section, and one of the biggest meets ever held by the company will result.

Blandburg—Langill & Edmundston, coal operators in Reade Township, on Sept. 9, secured an award of $11,686.86 from the Pennsylvania R.R. Co. on a charge of discrimination. They allege that the Pennsylvania R.R. Co. would not construct a siding to their mines and that partiality was shown in the awarding of coal cars. The case was the first of its kind tried in Cambria County. The plaintiffs asked for damages in the sum of $100,000.

Monongahela—After being closed down for more than five months undergoing repairs which have made it one of the greatest mines in the country the Mongah mine of the Pittsburgh Coal Co. was opened on Sept. 8. This mine when running full employs between 400 and 500 men. Since the mine closed down in April, the company has made improvements which by the time they are completed will cost in the neighborhood of $100,000. This does not include the $35,000, which was appropriated for the changing of the electrical power system.

California—Admitting that he had been guilty of violating the bituminous mining laws, Peter Brown, employed as a motorman in the Vesta No. 4 mine, was held for court recently. The information was made by Charles P. Byrne of the 21st Bituminous district, and accused Brown of having ridden on a loaded coal car when he was not motorman of the trip at various times within the past two years.

WEST VIRGINIA

Charleston—According to State Mine Inspector, Earl Henry, while the immediate effect of the European war has been to depress the West Virginia coal industry, the ultimate effect will be to help it materially. At present the inability of shippers to secure ocean-going vessels to handle coal for export has hampered a large possible movement, and the immediate industrial effect in this country, in the shape of lessened business, has also served to injure the coal trade. However, it is stated that with labor difficulties settled, prospects are excellent for the trade in West Virginia just now.

Eccles.—The bodies of two more victims of the April disaster have been recovered, in a portion of the mine which was flooded shortly after the explosion. This brings the number of bodies recovered up to 175. The mine is now operating with several hundred men at work, but as there are some portions which have not yet been fully cleaned up, it is possible that still other bodies will be found as work progresses.

Princeton—The coal traffic on the Virginian Ry. is becoming heavier and heavier each day. The train crews are running on full time, and the prospects are that the demand for coal from the Virginian section will continue to grow.

Clarksburg—Despite the reported business depression prevailing in commercial and industrial circles throughout the country, it is significant that the coal output in the Clarksburg district has materially increased. Before European hostilities were commenced the coal mines contiguous to this city were working only about two or three days each week. Within the last three weeks, however, the operations of the Consolidation Coal Co. have been working full time, while the same is true of the independent companies.

Bluefield—During the last fortnight, mining companies in the Pocahontas field have received numerous inquiries for coal from every part of the world. Particularly insistent are the demands from the great shipping ports of South America, the Straits Settlements, Japan and India and the ports of the Mediterranean. The price, according to the heads of some of the larger companies, is a secondary consideration, most inquiries bearing the agreement to pay the same prices, as have been paid for Welsh steam coals, which are ordinarily much higher than Pocahontas coals. It is stated that at all mining plants work is being conducted on full time and that thousands of men are needed for the Pocahontas region.

KENTUCKY

Lexington—The Kinkead Coal Co., of Lexington, has been awarded the contract for furnishing the Kentucky University at Lexington its coal supply for the current school year. Hywel Davies, business agent of the university, who is well known in the coal trade, received the bids and awarded the contract.

Louisville—Coal operators are much interested in plans for testing the Kentucky workmen's compensation law, which is now before the circuit court at Frankfort. The new system takes effect Jan. 1, and it is hoped that a decision will have been received from the court of appeals by that time, upholding the validity of the measure. Owing to the low rates offered for insurance under the law by the state, the stock insurance companies are opposing the measure strongly.

OHIO

Columbus—The Alma-Thacker Fuel Co., of Columbus, which was recently reorganized from the Pomeroy Fuel company has started to develop a tract of 2400 acres of coal land in Pike County, Kentucky. The property lies near the West Virginia line and the operating offices will be at Matewan, W. Va.

J. M. Roan, chief mine inspector of Ohio, is authority for the statement that hundreds of miners' children in the eastern Ohio district have been unable to attend school because of lack of clothing. A relief fund has been started.

Pomeroy—The Essex Coal Co. of Columbus will open another mine in the Pomeroy Bend district early in the spring. This mine, which will have a capacity of 1000 tons daily, will be a mile from the mine opened during the present year. It is located on a spur of the Kanawha & Michigan and will have modern equipment.

Wellsville—The four mines located near Wellsville, Ohio, which have been idle for more than four months, resumed operations recently.

Congo—Operations at Mine No. 301 of the Sunday Creek Co. were resumed recently after being idle for almost a year. The mine caught fire Oct. 31, 1913, and was sealed up under the orders of the Ohio Mine Inspector. Recently it was reopened and the fire was found to be extinguished. No. 302, which adjoins it was kept in operation all the time.

Cincinnati—The Otto Marmet Coal & Mining Co., of West Virginia, has filed a libel in the United States District Court here, as owner of the steamboat "Sallie Marmet," against the dredgeboat "Northern No. 2," owned by the Fieger-Austin Dredging Co., for damages alleged to have been sustained by two coal boats, loaded, in a collision which occurred on Sept. 1. About 21,000 bushels of Kanawha coal were lost, it is alleged, the total damages being fixed at $4500, for which it is asked that the dredge be sold. The dredge, which is engaged in government work on the Ohio, has been attached pursuant to the suit.

Cleveland—Operators with headquarters here have launched a vigorous protest against the proposal to tax freight bills three per cent. to afford revenues for the government,

pointing out that there is a vast movement of coal now going on, upon which prices were fixed by prior contracts made, of course, without reference to any such tax. It is declared that the trade cannot stand this burden, which would fall wholly upon the shippers. Congress has been approached on the subject through the Ohio delegation

Bellaire—It has been reported that one of the large coal mines in eastern Ohio would shortly make a proposition to its men to resume operations at the Pittsburgh scale for mine-run coal. It is said, also, that a number of Belmont County operators are considering posting notices at their mines, offering the men a referendum vote on the acceptance of the Pittsburgh scale, and offering employment to all who care to go back to work on those terms.

ILLINOIS

Lewiston—It is stated that within a short time coal will in all probability be mined on a large scale north of Lewiston, and the opening of this operation should add several hundred people to that town's population. It is alleged that John Skinner of Astoria, president of the Farmers' Bank, is backing this new enterprise.

OKLAHOMA

Bartlesville—It is believed by certain parties that coal in considerable quantities underlies the land south of Caney, and it is said that this territory will be developed. Already it is reported that a large acreage between Caney and Wann has been purchased, the parties so doing negotiating for other large tracts. Development of the property will begin as soon as some additional lands are secured.

COLORADO

Denver—The Policy Committee of the United Mine Workers of America recently called a convention of miners to meet in Trinidad, Sept. 15, to act on the truce terms submitted by President Wilson for ending the Colorado coal strike. Representatives of the mine operators also called a conference to consider and reply to the President's proposals.

FOREIGN NEWS

Toronto, Canada—The coal mining industry of Nova Scotia is more active than usual, orders having increased owing to the war. The output of the Acadia Coal Co. of New Glasgow for August was 30,470 tons, an increase of over 3000 tons over July and sales totalled 29,500 tons, an increase of 5000 tons. The output for August of the Intercolonial Coal Co. was 20,000 tons.

Cardiff, Wales—It is said that the British Admiralty has sent a representative to Cardiff to inform all shippers of high-grade Admiralty coal that the Government demands first option on all shipments. A certain number of cargoes have already been taken over under this order and are being laden for government account in vessels chartered by the Admiralty on time limits. The price paid is said to be $5.30 per long ton, and shippers are being indemnified against private claims for breach of contract. The chartering terms are $3.27 per gross registered ton per month for vessels up to 2200 tons and $3.03 for larger craft.

TRADE CATALOGS

Wolf Safety Lamp Co. of America, Inc., 47-49 West St., New York. Catalog. "Wolf safety lamps." Illustrated, 40 pp., 8x10 in.

The American Concentrator Co., Springfield, Ohio. "New Century Disintegrating and Washing Screen." Eleven pages, 6x9 in.; illustrated.

The Jeffrey Manufacturing Co., Columbus, Ohio. Bulletin No. 126. "Jeffrey Fans for Mine Ventilation." Thirty-one pages, 6x9 in.; illustrated.

Ingersoll-Rand Co., 11 Broadway, New York. Form No. 3024. Ingersoll-Rogler valves for air compressing cylinders. Illustrated, 28 pp., 6x9 in. Form No. 3030. Class ER-1 Ingersoll-Rogler air compressors. Illustrated, 20 pp., 6x9 in.

PERSONALS

H. J. Heywood, manager for the W. A. Gosline Coal Co., of Toledo, has been elected president of the National Coal Trade Golf Association, which was organized at the Country Club at Evanston, Ill., during the second annual national tournament of the coal trade golfers held there recently.

W. K. Field, president of the Pittsburgh Coal Co., has returned home from a visit to Europe of several weeks for recreation and on business.

John P. White and William J. Green, international president and secretary-treasurer, respectively, of the United Mine Workers of America, expect to tour the anthracite regions of Pennsylvania during the present month. Unless something unforeseen happens in the affairs of the union, Messrs. White and Green will remain in Scranton for several days addressing mass meetings in the city and vicinity.

R. Y. Muir, inspector of the 8th District in the Department of Mines of West Virginia, has resigned his position to take effect, Sept. 30, and accepted a similar position with the New River & Pocahontas Consolidated Coal Co., with headquarters at Berwind. John I. Absalom, of Montgomery, has been appointed as inspector to fill the vacancy made by Mr. Muir's resignation. He will begin his work Oct. 1.

OBITUARY

Thomas Lomax, one of the owners of the Lomax Bros. mine, near McArthur, Ohio, was instantly killed recently by a fall of slate in the mine. A shot blew away the supports and the roof fell.

James R. Black, aged 55 years, of Forward Township, Allegheny County, Penn., a prominent coal operator, died recently at the Memorial Hospital in Monongahela, death coming as the result of cancer of the liver and stomach. The remains were taken to Rices Landing for interment.

Lewis A. Powelson, assistant general agent of the Lehigh & Wilkes-Barre Coal Co., died recently after an illness of several months. Mr. Powelson was a native of New Brunswick, N. J., and at the time of his death was about 70 years of age. He became identified with the coal trade some 45 years ago, entering the employ of the Wilkes-Barre Coal & Iron Co., in its New York office in 1868 or 1869.

Charles Henninger, an assistant foreman at the Colbert colliery, at Shamokin, Pennsylvania, was instantly killed on Sept. 10, when he fell down a manway, a distance of 150 ft. He was "chasing gas" when he was overcome and stumbling pitched headforemost to the bottom of the manway, which was almost perpendicular. His neck was broken. A widow and six small children survive. His body was discovered by his brother, who was working in the same section of the mine.

CONSTRUCTION NEWS

Pineville, Ky.—The Continental Coal Corporation is planning to install a gasoline or acetylene lighting system in its commissary at Arjay, Ky., and is now getting prices on the equipment. F. M. Meadows, purchasing agent, is located at Straight Creek, Ky.

Chattanooga, Tenn.—The Chattanooga Gas & Coal Products Co. will let contracts in the immediate future, it is announced for the construction of its plant, which will manufacture coke and other products of coal. The chamber of commerce is furnishing the site, it is reported, and has secured an agreement from the company to begin work on the plant by Sept. 30.

New Orleans, La.—To facilitate the loading of coal from Alabama fields onto vessels at New Orleans, it is officially announced that the Illinois Central R.R. and the Southern Ry. will each erect tipples at New Orleans. The appropriations for the work have not been officially announced, although it is the general belief that it will require quite an amount of money to arrange facilities for the proper handling of the coal. Both the Illinois Central and the Southern have direct lines from the Birmingham fields to New Orleans, and it is presumed that they are taking this step in the face of the fact that as soon as work on Lock No. 17 is completed that Alabama can put coal into New Orleans by water. The tipples will be of structural steel, equipped with belt conveyers on which the coal will be dumped, thus discharging the entire car into the vessel with one operation.

Logansport, Penn.—The Allegheny River Mining Co., of which Dwight C. Morgan is president, and Fred Norman chief engineer, recently awarded the contract for a large tipple for the Nicholson No. 1 mine, to the Link Belt Co., of Philadelphia. This installation will be located on an exten-

sion of the Pittsburgh and Shawmut Ry., from Kittaning to Freeport. The coal will come from the mines in trips of 30 to 40 cars, will be dumped into hoppers and by means of feeders will be delivered to two inclined apron conveyors, the top section of which will travel horizontally for some distance to afford ample picking surface. From these conveyors the coal is delivered to shaking screens, where it will be sized and from there it goes to bins and is delivered to the railroad cars. The entire outfit will be of steel construction, of the latest design and as nearly fireproof as possible.

NEW INCORPORATIONS

Novinger, Mo.—The Davis Creek Coal Co. has been incorporated with a capital of $75,000 to develop coal land.

Indianapolis, Ind.—The S. W. Little Coal Co., of Vanderburg County, has decreased its capital from $300,000 to $150,000.

Pineville, Ky.—The Martin's Ford Coal Co. has filed amended articles of incorporation, increasing its capitalization from $40,000 to $60,000.

Red Ash, Va.—The Raven Collieries Co. has been incorporated with a capital of $15,000 to $50,000 for the purpose of coal mining. The officers are C. M. Rudder, Jr., president; J. S. Kahle, secretary, both of Bluefield, W. Va.

Jellico, Tenn.—The Jellico Coal & R.R. Co. has been incorporated with an authorized capital stock of $1,000,000. The firm has purchased 15,000 acres of coal and timber land in Kentucky and Tennessee, and will lease to corporations for development. It will also construct a standard gage railroad to connect the Queen and Crescent route south of Pine Knot with the Southern and the Louisville & Nashville railways.

INDUSTRIAL NEWS

New York, N. Y.—The Mashek Engineering Co., 90 West St., N. Y., recently sold to the Maryland Steel Co., two 22 tons per hour capacity briquette presses. These will be shipped and installed immediately.

Birmingham, Ala.—The Birmingham Fuel & Iron Co. reports closing a contract with the Louisiana Railway & Navigation Co. for 50,000 tons of steam coal for delivery over the next 12 months. This contract has for many years been with Western Kentucky operators.

Harrisburg, Penn.—The shipments of anthracite over the leading coal roads during the month of August reached the total of 5,483,743 tons, as compared with $5,369,900 tons in August of last year. For the eight months ended Aug. 31, the total shipments amounted to 43,821,389 tons.

Cincinnati, Ohio—Former Governor Judson Harmon and Rufus B. Smith, receivers for the Cincinnati, Hamilton & Dayton R.R. Co., have applied to the courts for permission to issue $3,000,000 recevers' certificates to purchase new equipment in the line of locomotives and coal cars.

Fayetteville, W. Va.—The number of freight cars loaded with coal and run into Clifton Forge during the past week, shows an increase over the corresponding period of last year. The total number amounted to 4291, the average for each day during the week being 613. During the same week of last year the average was 457.

Knoxville, Tenn.—Officials of the United Mine Workers of America, District No. 19, recently in a conference with coal operators representing Eastern Kentucky, renewed the wage scale on the terms that previously prevailed. A similar conference was scheduled for Oswego with the operators of the Jellico District.

Louisville, Ky.—The towboat Enterprise, belonging to the Monongahela River Consolidated Coal & Coke Co., struck an obstruction in the Ohio River, Sept. 11, and sank opposite 35th St. Capt. G. W. Shaw, manager of the Monongahela at Louisville, said that arrangements would be made to float the boat at once. It is one of the largest operating in the river trade.

Washington, D. C.—Hearings before the Interstate Commerce Commission's investigation into allegations that coal roads have established embargos resulting in discriminations against shippers will begin before commissioner Daniels at Chicago, Jan. 20, 1915. Shippers and carriers have been invited to forward suggestions as to the points to be covered and will be given an opportunity to be heard.

Pittsburgh, Penn.—A deal has just been completed, whereby Joseph L. Styber, of Pittsburgh, Penn., and Charles L. Wather, of Woodlawn, Penn., have sold to John C. Shirer, of Columbus, Ohio, vice-president of the National Coal & Fuel Supply Co., of Columbus, 1280 acres of coal land in the Buchanan County, West Virginia, district for $52,000 cash. The coal is the Pocahontas vein and the property lies near Grundy, the county seat of Buchanan County.

Columbus, Ohio—It is believed that a conference of railroad and traffic managers will be held in Columbus the latter part of September to reach a conclusion as to what increased freight rates on interstate shipments, if any, shall be made by railroad companies in Ohio. Since the five per cent. increase allowed by the Interstate Commerce Commission there is considerable difficulty in apportioning the increase. Coal rates may be affected slightly.

Washington, D. C.—In order to take advantage of the demand which will be made upon it by foreign nations during the European war, the Consolidation Coal Co. has arranged to operate 207 offices in various cities in Europe. Two representatives have been chosen to go abroad to arrange for the opening of these offices. The letters passport asked for and secured for these gentlemen were sent by the ambassadors of Great Britain, Spain, France, Italy and Portugal.

Columbus, Ohio—The hearing on the application of B. F. Nigh, secretary of the Michigan-Indiana-Ohio Coal Association, for a change in the reweighing rules, pending before the Ohio Public Utilities Commission set for Sept. 25, has been postponed upon the request of the Baltimore & Ohio R.R. officials. This was agreed to by Mr. Nigh. The request for the postponement was based on the fact that there is an effort being made to agree on uniform reweighing rules for the entire eatsrn part of the country.

Washington, D. C.—Officials of the weather bureau and students of sun spots at the United States Naval Observatory are attributing the present cold weather to the extremely large spots now present upon the sun. The records indicate that these appear in regular cycles, and corresponding meteorological reports indicate that when these spots are present in great size the weather becomes either warmer or cooler. There are, however, variations more or less decided due to local terrestrial conditions from this rule.

Connellsville, Penn.—The iron trade is not at present encouraging to the coke makers of the Connellsville region. It is stated that coke producers are keeping down the size of their output and from present indications a further curtailment, though a slight one will take place in view of the present slackness in the demand. While stacks have been blown out, stock coke has been accumulating and although several furnaces are scheduled to blow in shortly, attention is directed to the fact that they may not use Connellsville coke as fuel.

New York, N. Y.—The conditions prevailing in Europe at the present time have practically caused the suspension of transportation between the continent and the United States. The materials necessary for the manufacture of brattice cloth, as well as the cloth itself in the manufactured state have been held up, and the stocks in this country have suffered heavy drains on account of everyone wanting to stock up before the supply in this country had been sold out. There are, however, some stocks still remaining in most of the widths and in the regular qualities.

Norfolk, Va.—The coal mines of West Virginia are now largely supplying Europe with fuel through the ports of Norfolk and Newport News. Ten vessels all flying the flags of foreign nations recently arrived and anchored off the coal piers at Lambert's Point and Sewals Point awaiting an opportunity to get under the chutes to take on cargoes. Among the recent arrivals for coal are the Italian steamer, "Anada"; the Greek steamer, "Engenies"; the British steamers, "Etaline" and "Leslie," and the Norwegian steamer, "Bygland." All of these ships have or will be loaded with coal for English, French and Grecian ports.

Pensacola, Fla.—Captain Barrow of the coast steamer "Tawang Tarpon," recently arrived in Pensacola and reported sighting a cruiser anchored some miles out from Pensacola. While the vessel had no flags flying, it is believed that it was a German cruiser waiting for coal that left Pensacola a few days ago. The Hamburg-American (German) steamer "Navarre" recently left Pensacola for Pernambuco with 6000 tons of coal which was paid for in gold, but instead of going to Pernambuco headed toward the cruiser, and it is believed delivered her the coal. The "Navarre" has since then made several trips with coal, which is believed to be for the cruisers standing out from Pensacola.

Coal Trade Reviews

General Review

Anthracite slowing down to a more normal basis but an active winter anticipated. Bituminous showing indications of heaviness in all directions. Export business relieves the tension at some points. Domestic grades steadying up while the steam sizes are in excess supply and weak.

The customary month-end rush for coal, supplemented by some record breaking low temperatures, precipitated an active situation in the anthracite trade over the first part of the current month. The market has now steadied down to a more normal basis, but full time operations are the rule at the collieries and there are few sales at concessions on the regular circular. There is accumulating evidence of postponed summer buying on the part of domestic consumers so that the season is opening with less than the usual supplies on hand. The Lake movement to the Northwest is also considerably less than requirements and it is possible that rail shipments may have to be resorted to before spring. The winter outlook in hard coal has seldom been more favorable.

There are unmistakable evidences of adverse developments in the bituminous trade. Coal is now being released in markets where there were recently strong indications of a shortage. Though scarcely perceptible at some points, the slowing down is general in all directions. Heavy export shipments at a few of the Atlantic Coast ports is the only development of a constructive nature and this, of course, does not help the markets suffering from the restricted consumption among steam users. This foreign business is notably heavy at Hampton Roads and from the amount of chartering there are no indications of any let up. But in other lines the inquiry for both current and future shipments has disappeared almost entirely and operators are frankly regretting their cautious position when orders were recently plentiful.

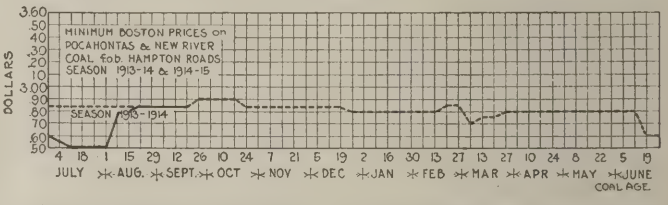
The curtailment in general manufacturing in the Pittsburgh district, supplemented by an abnormally lean season in Lake trade has created a dull situation there; demand is even further reduced and quoted prices are purely nominal. With the Canadian markets at a complete standstill and no prospects of any improvement in sight the outlook is not encouraging.

Steam grades are uniformly heavy throughout Ohio whereas the domestic sizes are in short supply. An increased demand from the Northwest has developed which, together with a stocking movement among householders, has resulted in a heavy demand for the screened grades. On the other hand, general manufacturing and steam consumption is far below normal and the problem of finding a disposal for the excessive production of these sizes, occasioned by the large output of domestic coals, is becoming increasingly difficult. The market on the steam sizes is approaching demoralization.

The Southern market is also feeling the effects of the slowing up in manufacturing, shipments being confined closely to contracts and some demurrage coal beginning to appear. However mines are on a fair running schedule and there is considerable business being negotiated with South America which is creating an optomistic feeling in trade circles.

The general discrepancy in the demand between steam and domestic coals has reached its highest development in the Middle Western field. While the domestics are steady to firm the steam grades are under heavy pressure and threatening to touch new low levels.

ATLANTIC SEABOARD



BOSTON

A dull period in Hampton Roads coals coastwise, although export demand holds up fairly well. Georges Creek also slackens some but prices show no change. Anthracite passes through a mid-month dullness.

Bituminous—The strong market predicted a month ago is slow in developing. Coastwise the movement has slackened again and were it not for the active export trade the market here would be a precarious situation. The off-shore demand is holding out well and prices are firm at $2.85@3 for Pocahontas and New River at Hampton Roads. The lower figure is still the ruling price for cargoes to New England but there is almost an entire absence of inquiry for both the present and the near future.

Inquiry at the distributing points for inland delivery continues light also. Few of the large consumers are making any heavy draft on their supplies and it is hard to see any buying power ahead for some time. In almost every direction there has been a marked let-up in bituminous, and shippers who declined orders a few weeks ago are repenting of their extreme caution.

That the Georges Creek coals are sharing the dullness to some extent appears in renewed shipments to Philadelphia and New York for coastwise loading. In other words, the over-sea business is not now absorbing the entire output and coal will be available for requisitions here that looked for a time as if they might be neglected.

Aside from short periods of car shortage the Pennsylvania operators seem to be enjoying a fair volume of business. There is a lull for the moment but the opinion is that present price levels will be maintained on the grades that have regular established markets.

Water Freights have eased off to the range that prevailed prior to Aug. 1, 60@65c. Hampton Roads to Boston on fair sized tonnage. The flurried inquiry of a few weeks ago seems to have entirely disappeared, and vessels are as much a drug on the market as at any time in the early season.

Anthracite—The early September demand seems to have been met with no difficulty and just now there is a hiatus in hard coal shipments for a week or so until the last of the month business starts in. The companies are well supplied with orders for loading after Sept. 20, but meanwhile there is a dull period that was hardly looked for. A few days of cool weather would accomplish a lot for the present market. Stove size, however, seems in no better supply.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*.....	$0.90@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*.....	2.15@2.80	2.50@2.90	2.92@3.02	
New York*.....	2.40@3.10	2.80@3.20	3.22@3.32	
Baltimore*.....	.....	.....	2.85@2.95	
Hampton Roads*.	.....	.....	.....	$2.85@2.95
Boston†.....	.....	.....	.....	3.63@3.78
Providence†.....	.....	.....	.....	3.68@3.78

* F.o.b. †On cars.

NEW YORK

Bituminous quiet but steady. Expected improvement fails to materialize but the market is well maintained. Anthracite has slowed down materially as compared with the month-end rush. Full circular price prevails and mines running up to maximum capacity.

Bituminous—The bituminous market continues quiet and there is little demand for spot coal, but on the other hand there is no accumulation of consequence and there is an absence of demurrage coal at the piers to be sacrificed at low prices. There is a fair movement on contract shipments. While it is difficult to estimate the amount of tonnage moving on this class of business, it is probably safe to say that contractors are taking perhaps 75 to 80% of the normal.

In some quarters an increase in price and a stiffening of the market has been looked for on account of the demand for export coal. In view of the fact that the English mines are getting out a practically normal tonnage, and the further fact that there are now plenty of bottoms available, there has been a decided easing off in the demand in this direction; this undoubtedly has a depressing effect on the market here which is tributary to Pennsylvania coals.

In fact the loss of bunker business in New York Harbor, on account of the tieing up of shipping, has been so heavy that it will much more than offset any additional off-shore trade that may have been gained.

Car supply is still good and it is generally conceded that we will not have any great shortage in the immediate future. There is, therefore, no reason to expect any great inflation of prices on soft coal this fall and those who have their tonnages contracted are fortunate under the conditions.

There has been practically no change in prices of coal at tidewater or along the line for Eastern movement and we continue nominal quotations of last week as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.55 @2.65; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

Anthracite—The anthracite situation is somewhat weaker. The war scare, together with the fact that a great many dealers wished to take advantage of the last advance of ten cents, created heavy buying during the latter part of August which was abnormal for that time of the year. The orders in some quarters were up to the winter demand and it would naturally follow that the business at this time would be a little lighter. The conditions are, however, by no means discouraging as anthracite coal is moving in practically all sizes at about circular prices and the mines are all operating on full time. It must be remembered that each day now brings us nearer to the October demand which is always heavy, being, as a rule, about the best month in the anthracite year. The weather is open and the movement of coal is in no way hampered either at the mines or along the line.

Stove size continues in heavy demand and few shippers will accept orders for it unless accompanied by a proportion of egg or chestnut. Of the three sizes, egg is a little heavy. The movement of pea to rail points has improved materially and with the advent of any cold weather this size will unquestionably be in strong demand in the New York market.

The retail trade locally is in fair volume, but inasmuch as this market is considerably nearer the mines than the more distant points in the East, North, and West, there has not been the urgent demand here that has existed along the line; New England and Western points figure on two to three weeks for delivery.

The demand for steam sizes in the better grades continues good, whereas the inferior coals are still a drug on the market, although there is probably less accumulation at tidewater than for some time.

The market is now quotable about as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.10	$4.60@5.10	$5.05	$4.55@5.05
Egg	5.35	5.15@5.35	5.30	5.00@5.30
Stove	5.35	5.35@5.45	5.30	5.30@5.40
Chestnut	5.60	5.45@5.60	5.55	5.30@5.55
Pea	3.55	3.45@3.55	3.50	3.40@3.50
Buckwheat	2.80	2.65@2.80	2.50@2.75	2.10@2.75
Rice	2.30	2.15@2.30	2.00@2.25	1.50@2.25
Barley	1.80	1.70@1.80	1.75	1.45@1.75

PHILADELPHIA

Cool weather increasing anthracite deliveries, both wholesale and retail. Prices well maintained on all sizes. Unusually heavy business anticipated this winter.

Anthracite—The cool weather has had the effect of stimulating the anthracite trade. Householders with empty bins found the evenings rather uncomfortable, owing to a temperature as low as 40°, and a visit to the coal dealers was the result. It is undoubtedly a fact that domestic consumers postponed purchases this year, as many dealers claim that the demand during the spring months was not as heavy as in previous years. The fall and winter business is, therefore, likely to show a substantial increase over the corresponding period of last year. Prices on all sizes are well maintained, with the exception of special prices to move coal that is likely to incur demurrage.

Tidewater business continues good. While the orders are not coming in with such rapidity as to cause any unusual delay in filling, at the same time the volume of business about keeps the large fleet of barges moving from this port. Prices rule about as follows:

	Circular	Individual
Broken	$4.75	$4.75
Egg	5.00	5.00
Stove	5.00	5.10
Chestnut	5.25	5.00 @ 5.10

BALTIMORE

Some improvement is noted. Exports are still increasing. Demand generally stronger and price list a little stiffer.

There is less inclination to let go of coal at sacrifice figures, and it is gradually developing that there is more inquiry. The price list shows a slight improvement. West Virginia gas slack, that recently sold as low as 45c. in spots, is now generally commanding ten cents or better. Gas three-quarter is holding firm at from 85 to 90c., and steam coals of West Virginia are selling around 95c. and $1 at the mines. Pennsylvania low-grade coals were still procurable at about $1, with medium grades calling for from $1.10 to $1.20 and best coals at $1.35.

The export business keeps increasing. Considerable coal is being loaded here for South America and Mediterranean ports. The charter list for the next two weeks loading also assures a continuance of this trade on an extensive scale. While two or three large firms continue to ship the bulk of this business, several smaller ones are known to be negotiating for European or South American connections.

The Anthracite Trade is also showing signs of awakening. While ordering is not yet extensive, cool weather has stimulated interest and small-lot orders are noted. Supply of some sizes is limited. The mines cannot supply all orders in full for the present.

In the coastwise trade there has been an inclination to tighten rates under a slightly increased movement to south Atlantic and gulf ports. The rates in some cases are ten to twenty cents over those quoted several weeks ago. Northerly rates have held about the same for the past few weks.

HAMPTON ROADS

Export shipments continue heavy, with a good coastwise movement. Government taking coal for use of fleet. Prices firm and there is about a normal supply of coal on hand.

The movement of coal from Tidewater still continues to show up exceedingly well, large shipments of both export and coastwise being made. Shipments during the week have not been so heavy to the South American markets, although some have moved to Brazil and the Argentine. Prices are remaining firm, and while it is understood that $3 is being asked by some of the suppliers, it is not believed that many sales are being made at this figure, and it is more than probable that $2.85 to $2.90 is the prevailing rate.

Export shipments for the week have gone to Port Said, St. Lucia, Port of Spain, Cristobal, Santiago, Buenos Aires, St. Thomas, Havana, Genoa, Piraeus, Naples, Para, Manaos, Georgetown, Gothenburg and Kingston. It is understood that the shipment moving to Port Said, Egypt, is for Dutch vessels trading there which have been using Welsh coal; war conditions have made it difficult for them to secure this grade now.

The accumulation of coal at the various railway yards is slightly above normal, but there is quite a large amount of tonnage in port and about due which will greatly reduce this.

LAKE MARKETS

PITTSBURGH

Demand decreased slightly and no stimuli given by the heavier exports from other districts. Mining operations at not over 60% of capacity, and prices as generally cut as before.

The Pittsburgh district has felt no favorable effects from the larger export trade being done by Pocahontas and other districts, while on the other hand it is suffering from the war through a curtailment in the domestic demand. Industrial operations have all slowed down and promise to decrease further. All hopes of an improvement in the Lake trade have naturally been abandoned, for the next development will naturally be curtailment of shipments as the end of the season approaches. Domestic demand has not opened up to any extent, and with line demand decreased generally and Lake shipments poor the Pittsburgh district as a whole has lost ground.

Prices are cut as badly as ever, mine-run selling down nearly to $1, with slack at 50@60c. Operations are at not over 60% of capacity, against about 65% for two or three weeks past. Circular prices, purely nominal, remain: Slack, 50c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.50, per ton at mine, Pittsburgh district.

BUFFALO

Much complaint from the bituminous trade. Overstocks and poor manufacturing conditions cut down sales. Canadian buying less than in this country. Anthracite becoming more active. Tonnage scarce in the Lake trade.

Bituminous—Few shippers are expressing satisfaction with their trade. There is too much coal in the hands of the consumers and consumption is relatively light. The mines are running irregular, keeping production down to avoid car service. The Canadian market is growing worse from week

to week. Many shippers are now exacting prepayment for everything sold there, and with money so scarce and heavy contributions for war purposes now being made, it looks as though the Canadian market will be tied up for a long time. This is a serious matter for Buffalo. Interest is now centered on the trade of South America, but there are many obstacles in this direction.

There is a special dullness in the slack coal trade at present, sizes remaining as usual. Quotations are $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.15 for slack. Allegheny Valley sizes are about 25c. lower than Pittsburgh, with slack about on a par with it.

Anthracite—The fall trade is setting in fairly strong and the movement is expected to be up to normal. In some sections there was coal carried over last winter, and in others some special buying has been done on account of war conditions, but otherwise the trade promises to be normal. Sellers of independent anthracite report that they can dispose of all their coal at full circular prices, and they look for it to go above circular as soon as the demand becomes stronger. There is complaint on the part of anthracite shippers in the Lake trade that they are not able to get as much as they require. One leading shipper reports that he has not enough on hand to satisfy his Lake trade alone. The demand is general, but the shippers do not relish a shortage on the far side of Lake Michigan, to be satisfied on an all-rail rate Shipments by Lake for the week were 90,000 tons, of which 64,000 tons cleared for Lake Michigan, a specially large proportion for any time of the year.

TORONTO

Domestic coals showing a steady improvement. Steam grades are weak.

With the setting in of cool weather, the market for domestic coal shows increased activity, and the demand for steam fuel is fair, though by no means up to normal, as manufacturing remains quiet. Supplies are coming forward freely, large consignments being received by water in preparation for the approaching close of navigation. Quotations are as follows: Retail, anthracite, egg, stove and nut, $7.75; grate, $7.50; pea, $6.50; bituminous steam, $5.25; screenings, $4.35; domestic lump, $6; cannel, $7.50. Wholesale, f.o.b. cars, three-quarter lump, $3.83; screenings, $2.89.

TOLEDO

Domestic coal in better demand but steam fuel continues inactive. Lake shipping much better than earlier in the season. Car shortage has begun to threaten the Toledo market.

The coal situation is showing little change although there is some natural improvement as the season advances. Steam coal is weak and the demand light. Domestic grades are picking up in demand although prices remain unchanged. The Lake shipping is more active than earlier in the season but is lighter than it would be if the ore demand was not so curtailed; there is little movement of ore as compared to normal seasons.

The country demand has been good. The Pittsburgh No. 8 field is still closed down and at present there is little prospect that the operators and miners will get together. The car shortage is beginning to apper although as yet there is little difficulty in securing an adequate supply but now that the grain movement has begun in earnest some trouble is anticipated.

COLUMBUS

Good demand for domestic grades and lake business active. Steam sizes weak. Some coal sold for freight charges.

With a good demand for all domestic grades and a considerable tonnage going to the Northwest, the local trade has been fairly active. The worst feature of the market is the weakness in the steam grades, which is accounted for by the fact that manufacturing is at a low ebb. The general tone of the market is fairly satisfactory, however, and future prospects are favorable.

Domestic Trade is steady in every section. Dealers are busy taking care of their customers and there is a preference shown for the fancy grades. Pocahontas and re-screened varieties are selling well and there is also a good market for anthracite. Domestic prices are ruling firm and dealers' stocks are only fair; most of the buying is for immediate delivery.

The Lake Trade is active and a considerable tonnage is moving toward the Northwest. Boats are being chartered for the remainder of the navigation season. Docks in the upper Lake ports are in good shape generally and some movement to the interior has been started.

Steam Business is slow in every section. Requisitions for manufacturing plants are not large and railroads are using only a limited amount. Many of the steam users are buying on the open market at extremely low prices. Railroad fuel contracts are still hanging fire.

Production in Ohio mining districts which have signed the wage agreement, is steadily growing larger. In the Hocking Valley the output is estimated at 85 to 90% of normal and the same is true of the output from the Pomeroy Bend district. In the Crooksville district a considerable tonnage has been produced. Massillon is also busy.

The small sizes are weak; nut, pea and slack was sold during the past week as low as 25c. In some cases cars have been taken for freight charges. This state of affairs is due to the large Lake production coupled with the slow steam demand.

Prices prevailing in Ohio are:

	Hocking Valley	Pomeroy	Kanawha
Re-screened lump	$1.70	$1.75	$1.65
Inch and a quarter lump	1.60	1.60	1.55
Three-quarter inch	1.40	1.45	1.40
Nut	1.30	1.50	1.20
Mine-run	1.15	1.20	1.10
Nut, pea and slack	0.35	0.40	0.35
Coarse slack	0.25	0.30	0.25

CLEVELAND

Coal receipts heavy, particularly of the fine sizes, which have dropped 5c. a ton under the pressure. The Lake business too light to keep available tonnage busy, boats taking short cargoes to avoid laying up.

Although the retail demand is good, Pocahontas coarse coal was off at the opening of the week. Where $3.85 had been asked on prepared sizes the week before, the price was down to $3.60. Mine-run held up $2.75 and slack was offered at $2.40. Hocking has been sold as low as Fairmount because the mines have produced much more slack than they can possibly store. Mines are not permitted to use railroad cars for storage as formerly. Coarse coals were also easier with the return of warm weather. Last week cooler weather slightly increased the demand for all grades of coal, but natural gas is being produced here in such large quantities that people are getting to rely upon it more and more.

The Lake Trade is not much better than it was. While there has been improvement in some quarters the gain has been slight. The outlook in the Lake business is not promising so far as large shipping is concerned except in hard coal, the Lake markets having been neglected for Eastern and Canadian trade.

Prices for current shipment are as follows:

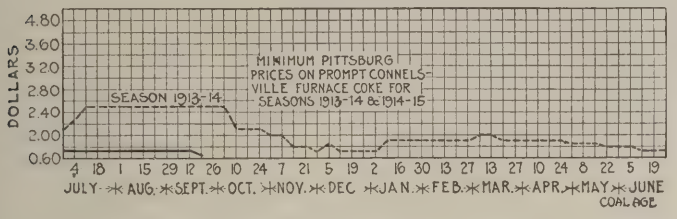
	Pocahontas	Youghiogheny	Bergholz	Fairmount	W. Va. No. 8
Lump	$3.60				
Lump, 6 in.			$2.45		
Egg	3.60				
Egg, 6 in.			2.10		
Lump, 1¼ in.		2.40	2.20		
Lump, ¾ in.		2.30	2.10	2.00	2.05
Mine run	2.75	2.15	2.00	1.90	1.95
Slack	2.40	1.55@1.60	1.55	1.50@1.55	1.50

CINCINNATI

Increasing domestic demand and decreasing steam consumption have created a difficult situation. Transportation facilities are unusually good for the season.

Unseasonably cool weather, together with the fact that most of the domestic consumers have now begun the storage of their winter supplies, has resulted in this demand increasing greatly. On the other hand, depressed conditions prevail in numerous manufacturing trades on account of the war. This has resulted in an unprecedentedly low consumption of slack for this season, which, with the large demand for domestic coal, places the trade in a most difficult position. Prices are naturally much demoralized, nut and slack being offered at ridiculous figures, with no takers.

COKE



CONNELLSVILLE

There is no market for coke at all,outside of occasional small lots of prompt furnace coke sold at concessions from previous quotations. It is rumored that as low as $1.50 has been done, but such rumors are not verified, and we quote prompt furnace at $1.65@1.70, or 5c. below the former quotation, quoting contract at $1.75@1.90, these quotations being purely nominal. Foundry remains quotable nominally at $2.25@2.35 for prompt and $2.35@2.50 for contract, at ovens.

Operators have no hopes of effecting sales at this time, the furnaces in operation being well covered and receiving ample shipments on contracts, resulting in occasional orders for suspensions.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Sept. 5 at

267,870 tons, an increase of 8187 tons, and shipments at 270,310 tons, an increase of 6197 tons. The figures are evidently exceptional since the general trend is towards decreased consumption of coke through the iron and steel industry slowing down.

BUFFALO

The demand for commercial coke is not improved. Shippers dislike to discuss the market, as it has so long been against them. Those who handle crushed coke find a better demand for it, but that would be natural, as it is a competitor of anthracite and will sell more readily from now on during the cold season. Iron ore receipts by lake are good, but the price of best 72-hr. Connellsville foundry is $4.25, with stock coke $3.30.

BIRMINGHAM

Unlike the coal market, coke has been little affected by the war. The demand for foundry coke is still small, and there is practically nothing doing in furnace grades.

ST. LOUIS

There still continues to be a small tonnage of byproduct domestic coke moving in from the East, with practically no new inquiries on foundry coke. Local gas house is moving fairly good, but not in the tonnage that has been anticipated.

CHICAGO

The market continues quiet prices being as follows: Connellsville, $4.90; Wise County, $4.75; byproduct, egg, stove and nut, $4.85; gas house, $4.25.

SOUTHERN

BIRMINGHAM

Business good and mines are working on fair schedules. Some South American orders have already been closed and more are pending.

Both orders and shipments of lump coal show an improvement over last week, although retail dealers, as a rule, are not laying in as large stocks as has been the custom in the past. Many of the operators are running only about four days a week but others are running full and are well supplied with orders.

As a result of the war, the steam business has improved to a large extent, heavy shipments being made to all Southern ports in view of the possible South American trade, and the increased demand from tramp steamers and others. Negotiations are still under way for the arrangement of bottoms and finances for the South American trade, and while matters have not been definitely settled, it is understood that the prospects are good.

Announcement is already made of the sale of two cargoes of coal by the Roden Coal Co. to be shipped to the Eastern coast of South America, one cargo to go from Mobile and other from Pensacola. That permanent trade relations will be established between the Birmingham district and South America, is freely predicted.

LOUISVILLE

Market heavy, due to slowing up of industrial consumption. Current business confined entirely to contracts. Demurrage coal beginning to appear.

The local coal market is demoralized. There is a big accuumulation of steam coal, caused by the rapid slowing up of industrial operations, while the demand for domestic fuel has been less than expected. The retailers seem to be well stocked up, and the consuming demand has not yet been brisk enough to require any additional orders.

For this reason, current business is slow, though the operators are shipping rather freely on business booked some time ago for September delivery, while October orders are also satisfactory. Some of the coal companies are selling for immediate delivery on a basis of the advanced prices quoted Sept. 1, but others are shading these quotations considerably and making other inducements in order to get the business. Reports from other large cities in this section indicate that the supply of steam grades is excessive in those markets as well as locally.

Shipments from the Jenkins and McRoberts plants of the Consolidation Coal Co. were heavier the past week than for a long time. European war has stimulated the Eastern Kentucky market to some extent.

Eastern Kentucky nut and slack are selling at 50 to 60c. for good grades; No. 2 run-of-mine is being offered at 80 to 90c.; straight run-of-mine at $1.10@1.20, block coal at $1.70 to $1.80, all f.o.b. the mines. Demurrage coal is being sold in Louisville at prices considerably under these figures. Western Kentucky grades are in about the same condition as the Eastern coals, and quotations run from 25 to 50c. a ton less, depending on the grade.

MIDDLE WESTERN

INDIANAPOLIS

Slight improvement in the general situation. Mines continue on same running schedules. Prices satisfactory, except on slack.

Prices have stayed at a comparatively low level for several months, and the indications are for an advance. The war, improved financial situation, colder weather and the expected larger movement of grain are all bullish factors. The only marked improvement now is in the demand for domestic grades, although there is a slight betterment in the steam sizes.

Prices are fair on all grades, but slack, which has a range of 45c. to 65c, No. 4 suffering the least depression. Mines continue to make better than half time. Operators have been considering again the possibilities of storing accumulating slack. The transportation situation is easy at present, but operators believe there will be a tightening up in October when corn begins to move. Retailers have not changed prices this month and seem content to have a fair movement to consumers' bins. The first spurt of the larger domestic buying is over, and the lessened demand for the time will give mines a chance to clean up on slack. The low prices for the latter tend to keep quotations on lump and other grades at a stiff level.

There are scattering reports of industrial improvement, especially at railroad shops and the big steel manufacturing plants at Gary are running at the top notch of the year. The August and early September movement of Eastern coals into winter storage has made holes in retailers' stocks, which they are again filling up before prices are enhanced.

ST. LOUIS

Domestic grades holding strong but steam market is threatening to establish a new low level. Railroads choked with steam coals.

The market continues good for high-grade domestic sizes, but is lagging on washed coal and steam. In fact, the steam market is about as low now as it has been in the past three years, and there are indications that it will establish some lew low records, as far as Nos. 4 and 5 washed and screenings are concerned. Screenings from the Carterville field are down to 30c., and No. 4 washed has touched as low as 25c. On the other hand, lump and egg are still strong at from $1.75 to $1.85 and in some cases $2. This unusual situation is due to the fact that the operators are unable to move their steam sizes, and the railroads refuse to give them more equipment.

The outlook continues excellent in the domestic market. In the Standard market screenings are down to 20c., and 2-in. lump is going at $1 although an effort is being made on the part of some operators to get it to $1.10; 6-in. lump is in good demand at from $1.25 to $1.35, while 3x6 egg is held at $1. The Standard market is not in the healthy condition that it should be at this time, but colder weather may bring about better results.

Anthracite still continues to move fairly good, with no demand for smokeless.

The prevailing circular is:

	Williamson and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	.....	....	$1.30	$1.00@1.10	$1.15
3-in. lump	.....	....	1.40	.....	.....
6-in. lump	$1.75@2.00	....	1.50	1.25@1.35	1.35
Lump and egg	1.85@2.15	$2.25	.....	.....	1.15
No. 1 nut	1.25@1.50	....	.....	0.75@0.80	.....
Screenings	0.70@0.75	....	0.80@0.85	0.20@0.25	0.35

No. 5 washed nut	0.30@0.40	....	.....	....	.....

CHICAGO

Prices on domestic coals increasing. The anthracite market is improving in all departments.

There have been advances in practically all the domestic coals but on the other hand there have been sharp recessions on certain of the steam sizes.

The demand for Carterville coal has been somewhat uneven. Some of the operators have sold up on their advanced circular price of $1.75 for the lump, egg and No. 1 washed. The demand has been so heavy that some have even withdrawn from the market temporarily. There is a slightly better demand for Indiana steam coal from some of the factories which seem to be expanding a little day by day. A decided increase in the demand for Indiana domestic grades has been noted.

The anthracite market is showing a progressive improvement. Both the dock and the all-rail trade have been active in all sizes. The smokeless coal market quieted down within the last week. The better grades of smokeless coal are selling at the circular price of $1.40 for mine-run; off-grade coals are not offered for less than $1.25 and in some cases for $1.30 or $1.35. The Hocking situation has been abnormal. The advance to $1.60 a ton has not retarded business in any degree.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.22@2.32	$2.65@2.80	$2.27	
Steam lump	1.87@1.92		1.97	
Egg		2.65@2.80		$3.30@3.45
Mine run	1.87	2.15@2.25	1.87	4.05@4.30
Screenings	1.07@1.12	1.45@1.55	1.07@1.12	

Harrisburg quotations are: Domestic lump and egg, $2.65 @2.80; steam lump, $2.15@2.20; mine run, $2.15@2.25; screenings, $1.45@1.55; No. 1 nut, $2.65@2.80; No. 2 nut, $2.30@2.40.

Prices for Carterville coal are: Lump and egg, $2.65@ 2.80 No. 1 washed, $2.80; No. 2 washed, $2.30@2.40.

KANSAS CITY

Wholesale and retail trade show little change though colder weather has stimulated the domestic demand. Prices are unchanged.

The price situation continues the main subject of interest. The expected increase of Sept. 15 now seems to have been postponed indefinitely; some say the present level will be maintained all winter but others are of the opinion that 25c. will be added Dec. 1, and 25c. a month thereafter. This is the first fall for several years that the price has not advanced Sept. 1.

The pronounced cold snap recently has forced many into the market and there is a chance that prices will advance, Oct. 1.

PRODUCTION AND TRANSPORTATION STATISTICS

ANTHRACITE SHIPMENTS

Anthracite shipments for August and the first eight months of this year and last year were as follows:

	August		8 Months	
	1914	1913	1914	1913
Phila. & Reading	904,643	855,343	7,768,256	8,616,490

FOREIGN MARKETS

ENGLAND

Trade quiet and slowly readjusting itself to the changed conditions. General reduction in war, insurance and freight rates.

The London coal trade is quiet. The prevailing hot weather keeps the consumption low. Supplies are coming in slowly, and the dislocation of the railway traffic has been pronounced. Manufacturing qualities are moving freely, and the export trade is reported better. Small nuts and slacks have been plentiful, and prices are weakening. Colliery quotations for house coals are still withheld.

One by one the barriers which held up the coal trade at the beginning of the war have been removed, and although the conditions prevailing previous to the outbreak cannot quite be renewed, everything possible to facilitate trade is being done. The reduction in war risks, insurance rates, and also in freight rates have further improved the situation; indeed, so low have the latter fallen that some shipowners have threatened to lay up ships.

To deal with the markets separately: Newcastle continues to show improvement in both prompt and forward business; the pits also are working slightly better. At Cardiff, too, matters are progressing much more favorably, and the demand in some cases has caused a slight increase in prices. In the Midlands trade is still quiet, though in the Yorkshire market a better inquiry is to be noticed. The market in the East of Scotland shows briskness, whilst that in the West has also improved.

The moratorium has been extended to October 4.

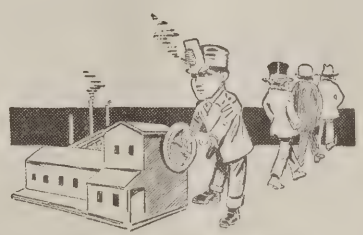
War risks insurance rates have been reduced from three to two guineas per cent. on cargo shipments. A reduction of a half per cent. in the premium on hulls has also been conceded.—"The Colliery Guardian."

COAL AGE

Vol. 6 NEW YORK, SEPTEMBER 26, 1914 No. 13

The Mainspring

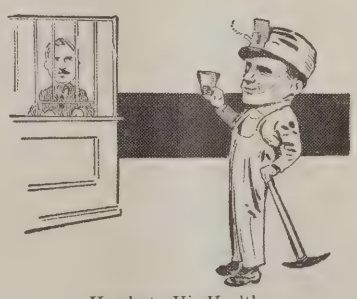
By Berton Braley



Written expressly for Coal Age

Pitboss an' foreman an' owner an' supe
Sure are a strong an' a heavyweight group,
Swellin' around with a satisfied smile,
Bossin' us miners an' livin' in style;
Still, when you're dealin' with figgers an' facts,
Gettin' right down to the simple brass tacks,
None of these big guns is makin' much flash
Side of the feller who deals out the cash.

A Heavyweight Group



Down in the mine where it's dusty an' dark,
Life ain't no picnic, no regular lark,
Danger is lurkin' all over the place,
There is a plenty of risks we must face.
What do we do it for—pleasure or fun?
No, sir, we work for the sake of the mon,
So when it's payday we all make a dash
Up to the feller who deals out the cash.

They Might Quit the Job

Foremen an' supers an' pitbosses, too,
Might quit the job, but we'd worry it through,
Managers leave an' directors resign,
Still we would manage to handle the mine,
But—if that feller who deals out our pay
Quits doin' business a week or a day,
Down shuts the mine with a clang an' a crash,
Work all depends on the guy with the cash!

So here's to his health, may he never grow pale,
But always have plenty of strength an' of kale,
The bosses an' foremen we mebbe might spare
But the guy with the payroll we foster with care,
We hope he will sit there right tight in his cage
An' slip us each payday a boost in our wage,
We love an' respect him—we never will clash,
With that there fine feller who deals out the cash!

Here's to His Health

The Fushun Coal Field in Southern Manchuria

SYNOPSIS—Some brief notes and a number of views of operations in this interesting district. The seam worked is 120 ft. thick. The pillar and stall system is used and sand filling is being tried.

The Fushun operations are situated about 20 miles east of Mukden, on a branch about 32 miles long from the South Manchurian Ry. There are in all five collieries called the Oyama, Togo, Laohutai, Yangpaipu and Chienchichai. They are all modern plants in every respect, those at Oyama and Togo being particularly up-to-date. The total production from all five mines aggregates over 7000 tons per day, and there are about 20,000 Chinese laborers employed, together with 1500 Japanese laborers and 500 officials of the same nationality.

THE OYAMA PIT ON THE LEFT AND THE TOGO PIT ON THE RIGHT

The coal in this locality was first worked about 600 years ago by the Koreans, who used the fuel for burning earthenware. On the Chinese occupation of the district, mining was entirely suspended. During the Russo-Japanese war the latter government took possession of the property and worked it on a small scale until the end of March, 1907, when both the mine and railway were transferred to the South Manchurian Ry. Co. On acquiring control of the property, this concern instituted an aggresive development propaganda at the Chienchinchai, Yangpaipu and Laohutai collieries, incidentally installing a great deal of machinery.

The coal measures belong to the Tertiary, the coal bearing rocks being mostly shales and clay, often carrying numerous fossil leaves. The seams extend east and west for a distance of nearly 10 miles along the strike and have a northerly dip, varying from 22 to 35 deg. Two seams have so far been discovered, but only the upper one has been developed as yet, the lower being of much inferior quality. The seam worked is 120 ft. thick and has many thin partings.

The coal is of excellent quality, particularly adapted to gas making and locomotive uses. The following is an average analysis: Water, 7 per cent.; volatile matter, 40 per cent.; fixed carbon, 48 per cent.; ash, 4 per cent.; sulphur, 0.8 per cent.

Mining operations so far have been conducted on the

VIEW OF THE COAL COMPANY'S PUBLIC HALL

pillar-and-stall system. Tests are now being made to test the practicability of sand filling. Stripping will also be used shortly, the local engineers crediting this country for turning their attention to this method.

An interesting feature is the great depth to which the

Residence of Vice-President N. Sakaguchi

shafts are sunk, one being 1160 ft. deep. As a rule, the shafts are of circular section, about 21 ft. in diameter and lined with brick throughout most of their length.

Co-operation between Operating Department and Office

By H. H. Warner*

It is a known fact that in any business there has to be coöperation between the various departments, if such business is successfully operated, and the coal-mining business is no exception. In quite a few instances, they lack coöperation between the operating department and the office which handles the details. If we trace this non-coöperation back, it will be found, as a general thing, to result from the failure of the mine manager or the one in charge to get the operating reports into the office in a satisfactory manner.

Of course, the accountant in charge can figure out this work in a way that will make a report which is nearly correct covering the operation, but nearly correct is not what the average coal company wants. In this business especially, every minute detail should be taken care of in a way that would be a positive record, and this can only be done by the mine manager or mine superintendent personally seeing that the requisitions for supplies, materials, time books, yardage books, etc., are absolutely correct before they enter the office to be recorded.

*Chicago, Ill.

At a well operated plant, you will find the mine manager or superintendent taking more or less interest in the various office details, and keeping in touch with all the reports that the accountant turns out, and also an interest in their value. By so doing, he sees where his accountant is going wrong on any one subject, and can at once explain the particular proposition, so that in the future it can be handled correctly.

The last statement pertains mostly to the handling of supplies, material and cost reports. Summing this co-operative plan up means nothing more or less than that the accountant in charge of the office detail at the mine should act as an assistant to the mine manager or superintendent in charge; there are quite a number of mine superintendents today who were at one time mine accountants, and they received their training through co-operating with their superior, who was either mine superintendent or manager.

The mine clerk or accountant's leisure time will be well spent if he devotes it to studying and investigating the operating department, and by so doing he will find that within a short time he will be able to handle more or less of the operating work with considerable intelligence, and that is the first stepping-stone to his success if he expects to stay in the mining business.

He must study mine management in order to coöperate with the operating department. In return, the mine manager or superintendent should study the office work, and, as before stated, should acquaint himself with the value of its detail if he expects to gain the main point—coöperation. By gaining this point, it will not only be a great help to him, but also to the company.

The Western Kentucky Coal Field and Its Relation to the Panama Trade

By A. Blair, Jr.*

Among the great mass of data published, speculating upon the possibilities of the American coal operators in the Panama coal trade, it is rather remarkable that the western Kentucky field has been almost completely neglected. This field comprises an area of approximately 4000 square miles. By water transportation via the Ohio River, it is some 600 miles closer to Colon than the West Virginia field; in fact, the western Kentucky district has a distinct advantage in this respect over any of the Eastern coal fields.

In recent issues of Coal Age the possibilities of water transportation via the Ohio River from the West Virginia fields were mentioned with the comment that this would prove "another great factor" in favor of these fuels. Some remarks were also made on the eastern Kentucky field, but the western districts were apparently ignored.

Of course it is understood that water transportation from any of these interior fields is contingent upon the development of a permanent year-around waterway down the Ohio River. The government engineers are now working on this phase of the problem, and it is only a question of time until a channel with a minimum depth of 9 ft. will be available.

As regards the western Kentucky field itself, water

*Superintendent, Pittsburg Coal Co., Henderson, Ky.

transportation is not an entirely new feature in that district. Previous to the advent of the railroad much coal was supplied river steamers and considerable shipped by these boats to mills and factories scattered along the river. But with the advent of rail transportation these river mines were gradually driven out of their markets. Most of these operations were confined to the banks of the Green River, which traverses practically through the center of the field and has excellent natural loading facilities; this river is navigable the year round. On the Ohio River the government engineers propose making a 12-ft. channel from Louisville, Ky., down, a depth which it will be impossible to obtain above that point. In a channel of this size a thoroughly sea-going barge may be used, thus doing away with the heavy additional charge of reloading at the gulf ports. It is thus clear that this field will enjoy a distinct advantage over other districts, in this respect at least.

The western Kentucky field consists, essentially, of the southern extremity of the Great Central Basin, which traverses western Indiana and almost the whole of Illinois. The principal seams being worked at the present time are known locally as the Nos. 9 and 11, from which about 8 million tons are being extracted per annum. There is also a lower seam of comparatively high-grade coal, which is exceptionally uniform in occurrence and quality over a wide territory. Owing to its great depth and comparative inaccessibility, it has not been extensively developed as yet.

This seam, known as No. 1, analyzes roughly about as follows: Volatile matter, 17.21; fixed carbon, 74.31; ash, 7.60; sulphur, 0.88. The seam is quite persistent over the greater part of the field, and seems to be comparatively free from faults or other geological disturbances. About the only important development in this section was done previous to the Civil War, and these plants were all destroyed by the union soldiers and have never been rebuilt.

There are other respects in which this district has an advantage over other fields as, for instance, in the labor supply. It is one of the richest farming districts in the country, and as is well known, such sections are always a strong attraction to good men. This is exemplified by the prevailing conditions in the field, no labor troubles or strikes of consequence having occurred in years.

In view of these substantial advantages, which this section has over other competitive districts, it should prove a large, if not the predominating factor, in the Panama coal trade, at least as regards the inland fields. The consummation of the river improvements, coincident with the completion of the Panama Canal and the consequent development of this new market, is regarded as particularly propitious. The district is already being investigated by powerful money interests, and will, no doubt, be the scene of a rapid development in the course of the next few years.

Discussion by F. R. Wadleigh

The eastern Kentucky coals cannot reach tidewater on freight rates that will enable them to compete. The western Kentucky field, while accessible by water to Gulf ports, has not the quality of coal required and could only reach a limited market.

Although the No. 1 seam may be a high-grade coal, covering a wide territory, Mr. Blair himself states that it is not extensively developed, "owing to its great depth and comparative inaccessibility." How much coal is being mined from this seam and on what data does he base his analysis and his statement that the coal "seems to be comparatively free from faults or other geological disturbances?"

The U. S. Geological Survey reports state that most of the workable coal in the western Kentucky field is confined to the Nos. 9 and 11 beds, No. 9 bed being about 300 ft. below the surface and No. 11 about 40 to 100 ft. higher. There is also a No. 12 bed mined in a few places, and Nos. 6 and 5 (so called) furnish a small amount of coal.

The analysis given of this No. 1 coal by Mr. Blair is entirely different from that of other Kentucky fuels, resembling greatly Pocahontas, although higher in ash. We have been unable to find in the Kentucky state reports any coal analysis like it. More knowledge about this seam of coal is desirable, as its large development, if feasible, would put an entirely different aspect on the possibilities of the western Kentucky district. However, it is not believed that the labor-supply question will give this field much advantage over its competitors; the output of coal per man per year in Kentucky is lower than the average for the country.

It is difficult to see why the western Kentucky field should be either "a large" or a "predominating factor in the Panama coal trade, at least as regards the inland fields." It has not at present sufficient tonnage of coals of the necessary quality, nor can these be placed at Colon at a lower price than the Eastern tidewater fuels, after the adjustment of water freight rates on the latter, due to the opening of the canal, takes place

The extent of the coal markets opened to United States fuels by the Panama Canal has been greatly exaggerated, and there will be the strongest kind of competition for this business by higher-grade coals than any in western Kentucky.

Electric Cables in Mine Shafts

Mining men recently discussed the question of aluminum vs. copper as a conductor for electric current in mine shafts. It was pointed out that aluminum is stronger than copper, but its conductivity is just about one-half, so that things are evened up. One authority stated that two 0.15 cables in a shaft are better than a single 0.3 cable; the bigger the cable, the stronger the armoring required. Continuity of current supply is the most important factor to be taken into consideration when installing shaft cables.

One engineer suggested that single-core, single-armored cables, put in wrought-iron pipes, take up the least room in a shaft, and the weight of such cables is such that they may be easily handled. The wires and the insulation are in compression instead of tension and less likely to develop faults. Another engineer preferred two separate cables, so proportioned that with one out of use the plant may be kept running till the damaged cable has been repaired. This arrangement serves two important functions—reduction of weight on supports and security of supply. A colliery manager stated that for mechanical strength, the paper-insulated, lead-covered and armored cable is unequaled, and is well suited for either shafts or roads in mines. In the case of twin or multicore cables,

the mechanical strength, as far as the resistance or crushing is concerned, is considerably increased by using sector-shaped conductors.

An electrical engineer told of a case where the shaft cables caught fire. They were bitumen cables and were in the upcast shaft. Coal was hoisted in that shaft for a considerable time before the main shaft was put into operation and much coal dust accumulated around the cables and cleats. There was also a certain amount of moisture in the shaft. One night he was informed that the cables were on fire, although they had no indications on the switchboard; the ground detector did not show anything and no fuses were blown out. They extinguished the fire with water and wet bags thrown around the casing.

They discovered that the fire was from the outside and not from the inside. The ultimate conclusion was that the fire had been caused by electrolysis, and it probably started in a poultice-like mass which had accumulated at the iron bolts. This had evidently set up heat sufficient to cause the casing to start burning.

This experience teaches a lesson relative to the use of wood in a mine shaft. It suggests plainly that all inflammable material should be kept clear of shaft cables.

Shale-Dust Grinding Machines at English Collieries

By Samuel Dean*

A shale-dust grinding plant is now becoming part of the general equipment at collieries in Great Britain. Figs. 1 and 2 show the Robey plant in use at many collieries, including Altofts and Bentley. There are two sizes, the smaller one for dealing with 8 to 10 cwt. per hour, and the larger 15 to 20 cwt. per hour, the effective hp. required being 14 and 20, respectively.

*Victor-American Fuel Co., Delagua, Colo.

The machine is self contained, the crusher being in such a position that the product falls direct into the granulator. Two separate drives are required. Screens fitted round the granulator can be adjusted to give the correct fineness of dust. The latter is of the revolving type mounted in ring-oiled bearings. There is a hopper under the machine fitted with a door for emptying the shale dust into cars or sacks. The cost of a plant capable of grinding 15 cwt. per hour complete is about $800.

American Mills Used at British Collieries

Ninety per cent. of the shale dust produced will pass through a 100-mesh screen. A number of Griffin mills are being installed and can be seen at collieries in South Wales, and at Denaby and Cadeby Main collieries, in

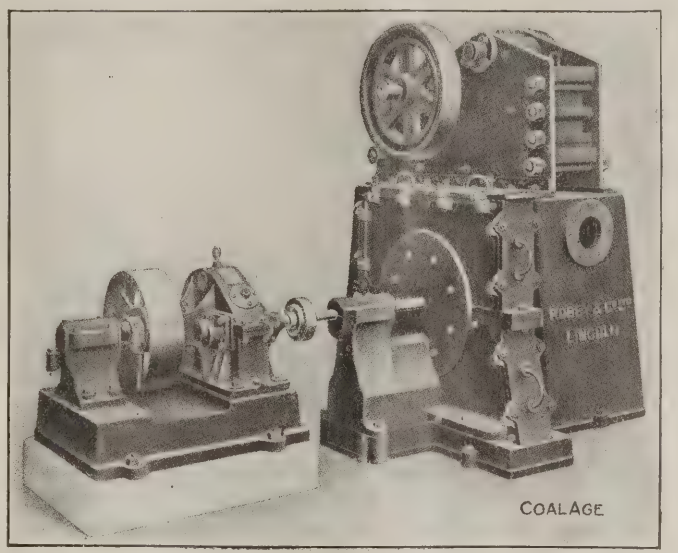


Fig. 1. Robey Pulverizer Plant with Intermediate Gear to Reduce Belt Speed

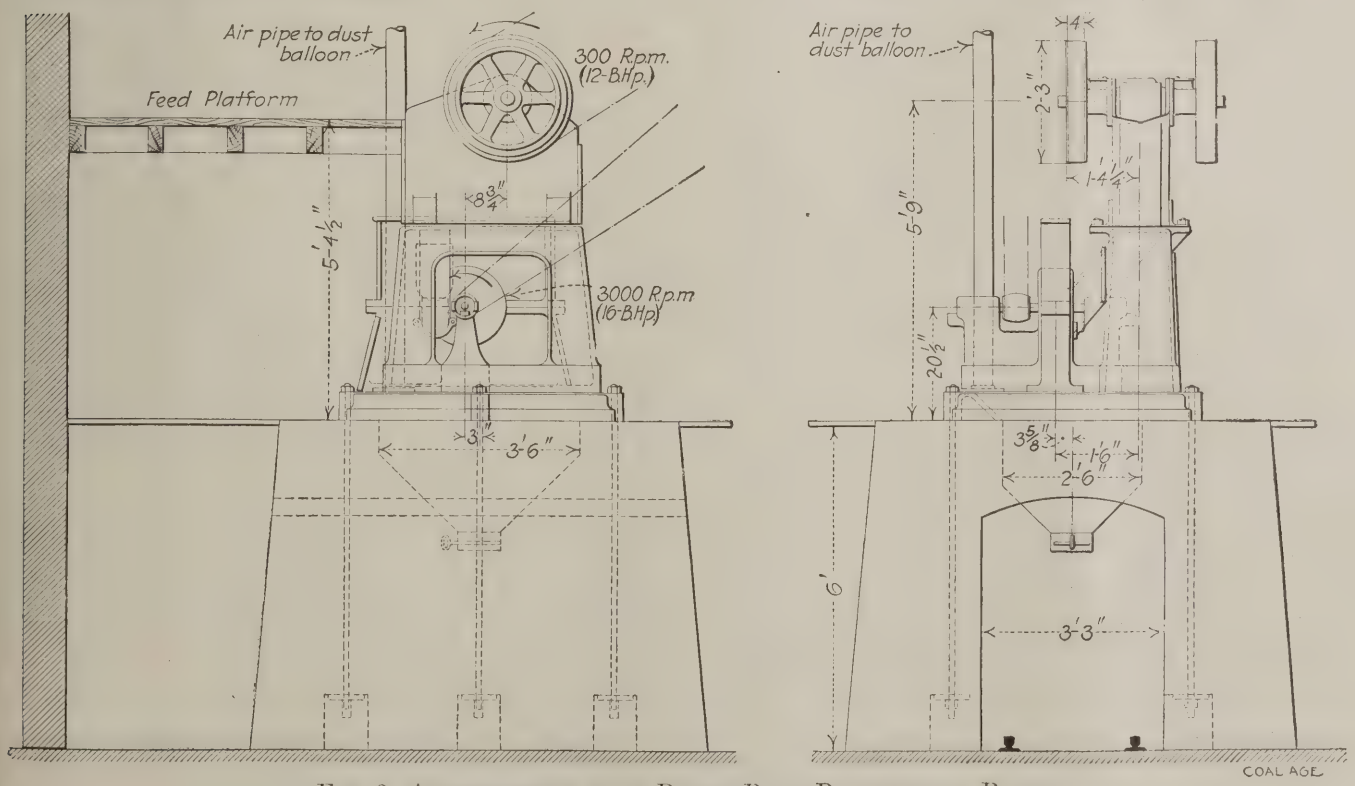

Fig. 2. Arrangement of a Robey Rock-Pulverizing Plant

Yorkshire. The Griffin mill is built in two sizes by the Bradley Pulverizer Co., of Boston, Mass., and produces a fine floury dust, about 90 per cent. passing through a 180-mesh sieve (180 holes per linear inch). The larger mill produces two tons of shale dust per hour, 55-60 b.hp. being required. The smaller or 30-in. mill produces one ton per hour and requires 25 to 30 b.hp.

The Griffin mill is well known and is in use in all parts of the world, being used largely for grinding the raw materials from which portland cement is made. The grinding is accomplished by means of a roller running

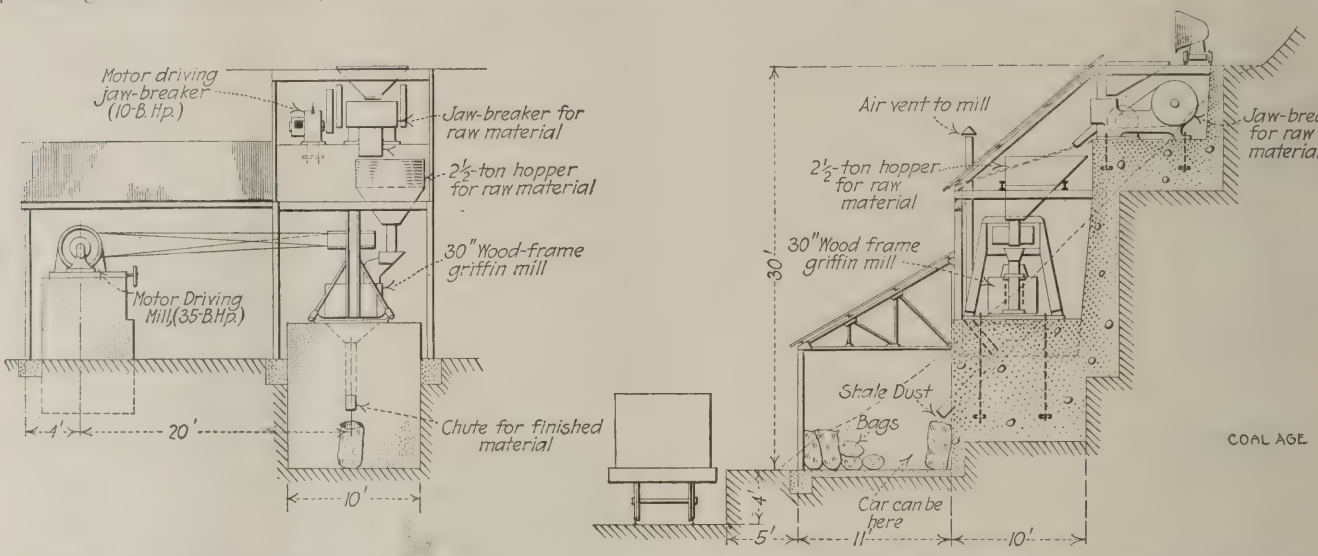

Fig. 3. A 30-In. Griffin Mill for Grinding Rock into Dust as Installed in British Collieries

within and against the inner surface of a die ring, being held in contact with it by centrifugal force. A 30-in. mill costs about $2000 and a 40 in. about $4000.

Coming Meeting of American Institute of Mining Engineers

The Pittsburgh meeting of the A. I. M. E. will be held Oct. 8, 9 and 10. The headquarters in Pittsburgh will be at the Hotel Schenley. There will be no formal program on Thursday morning, the first day of the convention. In the afternoon, however, a number of papers will be read, among which will be "Investigations of Coal-Dust Explosions," by G. S. Rice, and "The Appraisal of Coal Lands for Taxation," by H. M. Chance.

Thursday evening there will be an informal reception preceding an illustrated lecture on "Ancient Methods of Iron Manufacture in China," by T. T. Read. This will be followed by moving pictures of safety methods in mining, provided by the U. S. Bureau of Mines.

On Friday, at 9:30 a.m., the following papers on coal and coke will be read: "Coal-Dust Explosion Investigations," by J. Taffanel; "Coal-Mine Explosions Caused by Gas or Dust," by H. N. Eavenson; "The Pittsburgh Coal Field in Western Pennsylvania," by H. A. Kuhn; "The Book Cliffs Coal Fields, Utah," by R. S. Lewis; "An Aërial Tramway for Mining Cliff Coal," by A. E. Gibson; "Tin and Coal Deposits of the Fu Chuan District, China," by M. B. Yung; "The Manufacture of Coke," by J. P. K. Miller.

On Friday afternoon excursions will be made to the Homestead Steel Works of the Carnegie Steel Co., or McKeesport plant of the National Tube Co., Experimental Mine, Bruceton, and the Harbison-Walker brick factories. Definite arrangements for these excursions will be announced at the meeting.

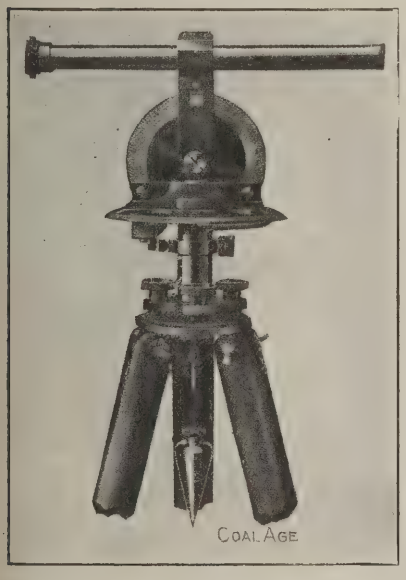
At 7:30 p.m., a subscription banquet will be held at the Hotel Schenley, the cost of which will be $3 per plate. Ladies are urged to be present. Business suits will be worn by men.

Following are some of the papers which will be read at the Saturday morning session, beginning 9:30: "A Test of Centrifugal Motor-Driven Mine Pumps," by S. S. Rumsey and W. F. Schwedes; "Gasoline Locomotives in Relation to the Health of Miners," by O. P. Hood; "Shot-Firing in Coal Mines by Electric Circuit from the Surface," by G. S. Rice and H. H. Clark. There will also be a general discussion on the use of electricity in mines, under the direction of the Committee on the Use of Electricity in Mines.

Electrifying the Anthracite Mines

The substitution of electricity for the direct use of both steam and compressed air in the anthracite mines of Pennsylvania is foreseen as a possibility in a paper read before the Engineers' Society of Northeastern Pennsylvania. The data for this "Historical Review of the Use of Electricity in the Mining and Preparation of Anthracite Coal in the State of Pennsylvania" was gathered this summer by a committee of electrical engineers, of which H. M. Warren, of the Delaware, Lackawanna & Western R.R. Co., was chairman.

In the summary of apparatus in service, the authors stated that the grand total of electric generating capacity and power purchased for use at the mines is given as 79,811 kw., which is approximately equal to 105,400 hp. The horsepower produced by steam at the mines is given as 531,289 in the last annual report of the Bureau of Mines of Pennsylvania. As 91,010 of this is used for electricity, this leaves 440,279 hp. produced by steam for direct use. Thus almost a fourth as many horsepower are transmitted electrically at the mines as are produced by steam for direct use.



The introduction of electricity in any great quantity into the mines is not more than two decades old. The first electrical installation was made in 1887 by the Pennsylvania company. In 1889 the Thomson-Houston Co. installed a locomotive and a generating station in the Erie colliery of the Hillside Coal & Iron Co. It is interesting to note that this locomotive was in service until 1911, or for a period of 22 years of continuous operation. The first electric pump installed was in 1890, and it has been in continuous operation ever since. From 1891 to the present year plant after plant has been installed in the mines and a gradual evolution has taken place.

Today there are 169 miles of wooden pole lines above ground and 754 miles of trolley wire below ground in the anthracite mines. There are 951 electric locomotives using an estimated amount of over 60,000 hp. The other electrically operated equipment consumes 19,170 hp. for breakers and miscellaneous machinery, 23,280 hp. for electric hoists, 38,500 hp. for electrically driven pumps, 2920 hp. for coal-cutting machines, 3650 for lighting and about 100 hp. for heating. There are now five breakers equipped with individual motor drives, and others are under course of construction.

An Improved Sighting Compass

There has recently been placed on the market by the Davis Instrument Manufacturing Company, Inc., Baltimore, Md., a simple improved sighting compass designed particularly for mining work.

As shown in the accompanying figure, this compass has both a vertical and a horizontal limb. The vertical circle reads to half-degrees, while the horizontal limb is graduated to read single minutes, by the assistance of a vernier. The instrument with its tripod weighs only 8 lb. As shown in the figure, the instrument is supplied with leveling screws and a shifting head that enables it to be quickly set up and adjusted for the giving of sights.

DAVIS SIGHTING COMPASS FOR MINING WORK

The distinct advantage possessed by this instrument over the usual form of sighting compass is the sighting tube, which has the appearance of a telescope although containing no lenses. The tube is equipped with adjustable crosshairs that insure accuracy in sighting.

Another important improvement is the provision made for sighting in a vertical plane, which enables the instrument to be used on steep pitches, with great accuracy. While this compass is designed for the use of mine superintendents and foremen in extending the sights given by the engineer or surveyor, it is also a convenient leveling instrument for the use of builders. When desired, an extra spirit level is mounted on the sighting tube, for the purpose of giving level sights, although this addition is unnecessary in the use of the vertical circle.

Illinois near the Head in Mineral Production

Illinois was third among the states of the Union in 1913 in the value of its mineral production, according to figures of the United States Geological Survey, compiled in coöperation with the Illinois State Survey. The state owes its prominence as a mining state chiefly to its importance as a producer of coal and petroleum and to the development of its clay-working industries.

In coal production Illinois is exceeded only by Pennsylvania and West Virginia, and in the production of petroleum only by California and Oklahoma. In the manufacture of clay products Illinois ranks fourth.

The value of the mineral production of Illinois in 1913 was $131,825,221, of which the coal mines contributed $70,313,605, or 53 per cent.; the petroleum wells $30,971,910, or 23 per cent.; and the brickyards, tile works, and potteries, $15,195,874, or 12 per cent.

In 1912, the value of the total mineral production was $123,068,867, including $70,294,338 for coal, $24,332,605 for petroleum and $15,210,990 for clay products. The total increase of $8,756,354 in 1913 over 1912 was therefore principally in oil production.

These figures do not take into account the manufacture of pig iron nor the manufacture of coke, the raw materials for which are imported from the Lake Superior region and West Virginia, respectively. In the manufacture of pig iron Illinois stands third, being exceeded by Pennsylvania and Ohio. If the value of these products in 1913 were added, the total value of the mineral products of the state would be increased by nearly $55,000,000.

Another important mineral industry of Illinois is the manufacture of portland cement, this product in 1913 having the value of $4,784,696, an increase of $1,340,611 over the previous year.

The quantity of natural gas produced in Illinois when compared with the output of the other fuels is insignificant; nevertheless in 1913 the value of this fuel was $574,015. Coal, petroleum and natural gas had a combined value in 1913 of $101,859,530, an increase of more than $6,500,000 over 1912.

Coal Mining in Alsace-Lorraine

The Alsace-Lorraine district, which has been the scene of more or less important battles in the European war, is quite an important coal producer. The output in 1913 aggregated 3,795,932 tons as compared with 3,538,722 tons in 1912. The coke production experienced a slight decline from 94,595 tons in 1912 and 91,745 tons in 1913.

About half of the entire production is consumed locally, and by far the larger part of the remainder is shipped to south Germany and the Rhine Provinces. Other consumers are Switzerland, France, Luxemburg, Austria and Italy.

Recent Developments in Byproduct Coke Practice

By William Blauvelt*

SYNOPSIS—Some notes on recent improvements in byproduct-oven construction, with particular reference to the Semet-Solvay process. Some figures on the enormous losses resulting from the use of beehive ovens are given. Comments and suggestions as to methods of coking are also included.

In 1913 the tonnage of byproduct coke amounted to 12,714,700 tons, or more than 27 per cent. of the total coke produced in the country. This is an increase of about 1,600,000 tons over 1912, and it is probably not far from the truth to say that by the close of the current year the production will be at the rate of 14,000,000 tons per year. Compared with 1910, this means a growth of 100 per cent. in four years.

From the U. S. Geological Survey reports it appears that the average value of the coke and byproducts obtained per byproduct oven in 1912 was $11,265, as compared with $1019 as the average yield per beehive oven. The total value of the byproducts recovered was over $16,000,000. If these had been recovered from the coal used in making coke in beehive ovens, they would have been worth approximately $80,000,000—at the prices ruling in that year. The average yield of coke from byproduct ovens was 75.3 per cent. and in beehive ovens 64.7 per cent., a difference in favor of retort ovens of 10.6 points, or 16.4 per cent. If this yield had been obtained from the beehive ovens, it would have added to the wealth of the country 5,390,000 tons of coke, if the same coals had been coked in byproduct ovens, in addition to the above value of the byproducts. This loss is equivalent to the absolute destruction of about 6,800,000 tons of our coal supply during the year.

I have given these figures as suggestive of the importance of the byproduct oven in the conservation of natural resources. In this connection it is interesting to note that recent work in some byproduct ovens is showing conclusively that the high-volatile coals of the Connellsville and Klondyke districts make byproduct coke quite equal to the best coke that can be made in beehive ovens from the same coals.

The map, Fig. 1, shows the distribution of the byproduct coke plants in the United States. There are 42 of these plants. The map shows that in almost every case the byproduct ovens are located at the point of consumption rather than at the coal mines, as distinguished from the almost universal practice with regard to beehive plants. In the five coke-producing states of the South, the percentage of byproduct coke is much larger than in the country as a whole. With the completion of present construction nearly half of the coke made in the South will be byproduct coke. This point is worthy of consideration in connection with the work the Southern states are doing in the conservation of their resources.

One of the most notable improvements which has been made in the industry since its introduction into this country is the increase in output per oven unit and per man employed. When the first ovens were brought over from Europe they had a capacity of 4.4 tons of coal per day, and one crew of men was capable of handling about 25 ovens. This gave a capacity of 110 tons of coal per day with a unit crew.

Today the most modern ovens have a capacity of 20 tons of coal per day, and improved organization and modern machinery permit practically the same crew to handle from 50 to 60 of these ovens, thereby coking from 1000 to 1200 tons, instead of the original 110 tons. I know of none of the other metallurgical industries which has shown a larger growth in tonnage efficiency in the same time. This is a conservation of labor well worth considering along with the conservation of our coal supply. Progress in this respect has been distinctly greater in America than in Europe.

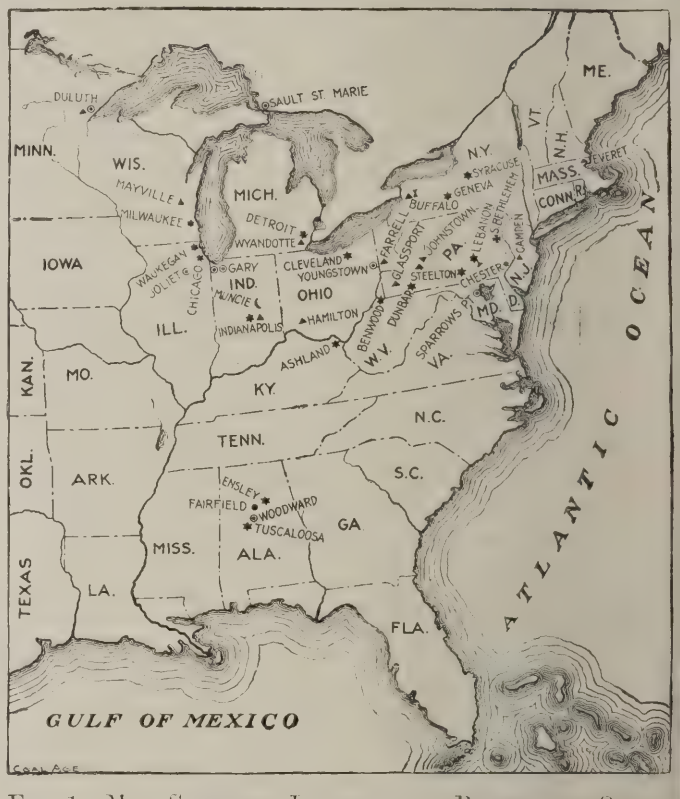


Fig. 1. Map Showing Location of Byproduct Ovens in the United States

Waste-Heat Ovens

The byproduct oven has been developed along two lines, the waste-heat oven, and the oven recovering the maximum amount of surplus gas. The former is the simpler type. It is ordinarily installed in places where the gas has little value. As is well known, in the carbonization of coal in a retort oven a portion of the gas produced is used for heating the ovens while the remainder is available for other uses. The waste-heat oven is not designed to obtain the greatest possible quantity of surplus gas and the products of combustion going off at a

*Consulting engineer, Semet-Solvay Co., Syracuse, N. Y.

Note—Paper presented at the sixth general meeting of the Iron and Steel Institute, New York, May 22

high temperature are utilized for raising steam. This practice is comparable with that employed in those beehive-oven plants where the tunnel-head gases are collected and led under boilers, and to the non-regenerative heating furnace with boilers for utilizing the waste heat.

With the growing use of machinery for the storage and preparation of coal and for the preparation of coke, and the substitution of machinery for hand labor in other parts of the process, the requirements for power have grown materially, so that the amount required for a modern coke-oven plant is very considerable. There are many cases where the most economic results are obtained by a plant, so designed that there is just enough heat in the waste gases to supply the steam required, leaving the remainder of the gas available for sale.

A boiler plant properly designed for waste heat, with its accompanying economizers for preheating the feed water, is the most economical apparatus for utilizing heat in an industrial plant; that is, such a boiler plant will deliver the gases to the chimney, or to the exhaust fan which often replaces the chimney, at the lowest possible

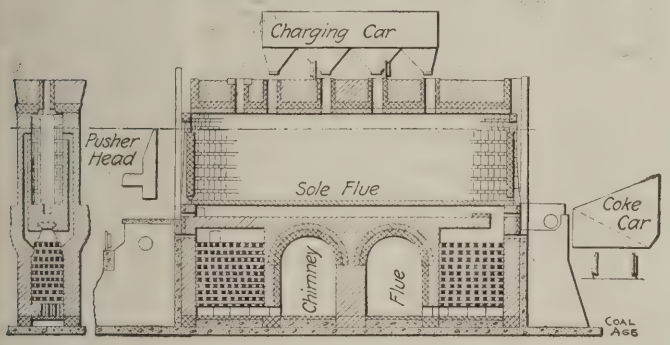

FIG. 2. SECTIONAL VIEW OF A TYPICAL OVEN

temperature consistent with commercial results. Such a design permits a very simple type of oven, with low first cost of operation. In the type of oven with which I am most familiar, the Semet-Solvay oven, these principles have been thoroughly developed, and under the conditions described above very satisfactory results have been obtained. A typical cross-section of this oven is shown in Fig. 2.

The gases are burned in the combustion flues, and then passed to the sole flue beneath the oven and out through the chimney flue to the boiler plant. The air for combustion passes first under the sole flue and then through the narrow flues on each side, where it comes into intimate contact with the heated brickwork; thence upward to the heating flues, where it meets the gas.

By a proper proportioning of these parts enough heat is abstracted by the air from the waste gases, so that the highest temperatures may be produced in the combustion flues, and at the same time sufficient heat remains in the waste gases to produce all the steam required for the operation of the plant, without any expense for fuel or for labor in firing. This system requires no attention from the operators except the regulation of the air at the burners on the one hand, and the maintenance of proper water supply to the boilers on the other. This method of heating the air is called "recuperation," to distinguish it from the familiar form of regenerator common to most high-temperature furnaces.

Fig. 3 shows an oven designed to operate with the smallest amount of fuel, and at the same time maintain, as far as possible, simplicity of construction and operation. In this design, regenerators are substituted for the recuperative system, one pair of regenerators for each oven, with the two chimney flues arranged between them. The whole construction of the oven and regenerator is located between the two vertical walls peculiar to this type of oven. These walls extend from the concrete foundation straight through to the top of the oven.

The operation of the regenerators is, in general, similar to that of on openhearth furnace, except that an entire block of 60 or more ovens is reversed at one operation. The air is usually blown in by a fan located beyond the reversing damper and is distributed under the block through a single chimney flue. It enters at the bottom of the regenerator, rises and passes through the flue system, meeting the gas at the several burners in the combustion flues. On reversal, the air enters the other regenerator, rises through the air flue, shown in dotted lines, and descends through the horizontal combustion flues, meeting the gas as before. The products of combustion pass out through the other regenerator to the reversing damper and stack in the usual manner. By this system the entire series of combustion flues are swept by all of the air required for combustion, so that hot spots are prevented and a uniform temperature is maintained throughout.

PROBLEMS IN OVEN CONSTRUCTION

Anyone familiar with the use of the high temperatures required in metallurgical work will realize the difficulties connected with the proper heating of a byproduct oven. The walls of the chamber are, say 36 ft. long and about 12 ft. high. Every portion of both of these chamber walls must be heated to a high temperature, and the temperature must be uniform in all parts, excepting that perhaps the upper part may be somewhat cooler. Any inability to control the temperature at any portion of this surface, about 430 sq.ft., means the production of imperfect coke, delay in the operation, or injury to the brickwork.

The method used in controlling the heat over this surface is interesting. It is illustrated in Fig. 4. The air raised by the regenerators to a temperature of about 1000 to 1100 deg. C. travels through the flue system, as described above. At the ends of the flues are gas burners, consisting of simple pipes, which admit the gas. When the air is traveling downward through the system it flows through the first flue until it reaches the first gas burner. The stream of gas is deflected downward by the air current and burns in the air as it travels through the flue. At the end of the second flue the air meets another stream of gas, which also is deflected downward and heats the third flue, and so on, until the gas from the last burner consumes the last of the oxygen.

When the air current is traveling upward the streams of gas are deflected upward, so that the entire combustion system is reversed at the usual half-hour periods by the manipulation of only one reversing damper for the entire block of ovens. A proper adjustment of the relative amount of gas delivered by each of the burner pipes maintains just the right relation between the heats in the different parts of the system, with the minimum attention. This method insures an even distribution of heat throughout the whole heating system. It seems clear also

that in the practice of passing the entire volume of air required for the combustion through the entire flue system there is a gain in efficiency of transfer of heat from the hot gases to the oven walls, as compared with the older methods of heating.

There has been some discussion as to whether the heating of a byproduct oven is effected by radiant heat or by convection and conduction, but I believe that the arguments are in favor of the latter theory. Under the conditions which exist in a coke oven the brick wall, at working temperatures, is a good conductor of heat.

This is illustrated by the fact that an increase of the thickness of this wall from 2½ to 4½ in. does not demand in practice a higher temperature in the flues to produce the same result in the coking chamber. The flame as burned in the oven flues is only slightly luminous, and it has been shown by good authority that the radiation from a non-luminous flame is only about one-third of that from a luminous flame. Moreover, radiant heat is transferred in accordance with the difference between the fourth powers of the temperatures of the radiant and receiving bodies, while heat is transferred by conduction proportionately to the first power of the difference in temperatures. It would therefore seem clear that under the conditions we are considering, at least a large portion

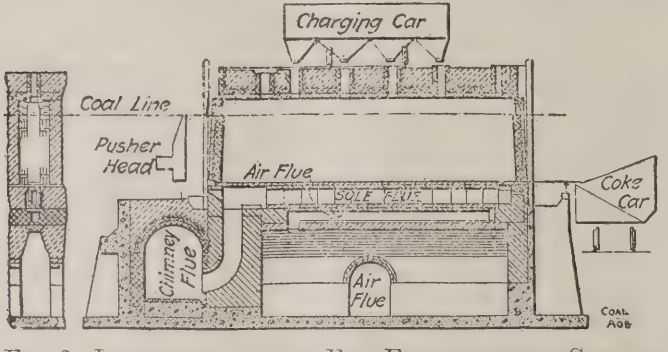

FIG. 3. LONGITUDINAL AND END ELEVATIONS IN SECTION

of the heat transferred from the hot gases to the flue walls must be by convection and conduction, and the system which uses this latter method is the more efficient.

In a system of heating flues where the layers of gases lying next to the walls are practically stationary, or moving slowly, it has been shown by experiment that these layers of quiet gases form an effective nonconductor which offers a greater obstacle to the transfer of heat than the wall itself. When the flow of gases is sufficiently rapid to sweep away these quiet layers, the hot gases are permitted to come in direct contact with the walls and transfer their heat to the substance of the wall according to the first power of the difference in temperatures, and the efficiency of transfer is proportionately good. The comparative rapidity of flow of the gases during their combustion also has the practical value of distributing the heat and preventing injury to the brickwork, avoiding thereby the dangerous condition which arises in an operation where temperatures are generated approaching the melting point of the refractory material.

Each burner on the Semet-Solvay oven is directly under the hand of the man in charge of the heats as he walks in front of the ovens, and each flue may be inspected by the removal of a plug from a peep-hole. The importance of convenient access both to the control of the gas supply and to the inspection of the heating flues in a block of byproduct ovens cannot be stated too strongly. With a given coal, the quality of the coke produced depends very much upon the maintenance of the proper temperature in the oven, not only as a whole, but in every part; nothing injures the quality of the coke more than inequalities in the heat in different parts of the chamber, so that certain portions of the charge are over-coked while the cooler spots are being finished. In an industrial plant it is essential that any important operation shall be done conveniently and in comfort to the operator, otherwise one may be sure that it will be done badly except under the closest supervision. Given good construction and simplicity of parts, the oven which permits the most convenient and accurate control of the heats is the best.

DISCUSSION BY CARL A. MEISSNER

The figures given in Mr. Blauvelt's interesting paper show in a striking manner to how great an extent our national coal resources, and the valuable byproducts derived therefrom, could be conserved by the more extensive use of the byproduct as against the beehive oven. He also describes the development made by his company in the construction of byproduct coke ovens in increasing their capacity and efficiency.

Mr. Blauvelt shows clearly how much has still to be done in this country in order to replace the beehive ovens by the byproduct ovens. The main reason for this is claimed to be the high initial cost of constructing a byproduct-oven plant as against a beehive-oven plant. I say "claimed to be," because when we consider all the costs—the conservation of the coal, larger coke yields, the recovery of the gas, tar, sulphate of ammonia, benzol, etc., in fact, all factors connected with the question of manufacturing coke from coal—it is not possible to present any figures that will not show a much larger return on the original investment from a byproduct coke-oven installation as against a beehive. This is the ultimate crux of the whole situation from a manufacturer's standpoint.

The advantages of better coking control, more uniform quality of coke, ability to collect and mix at one plant various coals, to improve blast-furnace operations, lessen the coke consumption and reduce the whole cost of making pig iron, as well as improve its quality for making steel, are all points that have to be taken into consideration.

Mr. Blauvelt refers to the gradual increase in capacity of ovens, which is governed largely by their dimensions and by the coking time. I am satisfied that we will be able to increase this capacity slightly with every new plant that we may build until the final limits, which will be governed by practice and experience, are reached. Great care must be exercised in doing this. I know of several cases where attempts were made to "jump" to greater dimensions with very unsatisfactory results.

As to the number of ovens to a battery and the number of batteries to a plant, this is again a matter for careful study and consideration. We have at Gary, Ind., 560 ovens and at Joliet, Ill., 280 ovens, and our experience has been that the operating cost per ton of coke at these two plants is practically the same. We feel that it would not be wise to place more than up to 100 ovens of American silica-brick construction in a battery nor install more than 600 ovens in a plant unit. The operative supervi-

sion becomes more difficult unless additional department heads are employed, which means increased cost, and where coke has to be "made right" in order to give the best results in a blast furnace, this operative supervision is a factor of prime importance.

Coking High-Volatile Coals

The most important question that has probably delayed more serious consideration of byproduct coke-oven installations and prevented greater progress in this direction, has been whether high-volatile coals can be coked in byproduct ovens so as to give as good a blast-furnace coke as many of them do in beehive ovens. This refers particularly to the great Connellsville and Klondike coal regions, though it also affects many other districts having high-volatile coals heretofore not considered fit for coking even in beehive ovens. Mr. Blauvelt refers to his successful experience with the use of high-volatile coals and all of our experience in this direction shows that many of these can be coked to the extent of 100 per cent., so as to give a good blast-furnace coke, while in other cases suitable coke is made by the admixture of 10 to 35 per cent. of low-volatile coals. Even those coals which have been considered by many as not being at present available for coking purposes—such as certain sections of the Pittsburgh seam, and those of a great many other coal districts—have been and are being used to make a satisfactory blast-furnace coke by being mixed with larger quantities of low-volatile coal, up to 60 and 80 per cent. of the latter being used.

There can be no further question in my mind that the present types of byproduct coke ovens have solved the problem of ultimately being able to utilize for coking purposes in a greater or less degree almost any bituminous coal found in this country. Even anthracite coals are mixed in small proportions with some of the high-volatile coals in Germany and have been found to make a more satisfactory coke than some of these high-volatile coals when coked at 100 per cent.

In view of all the above, the point of keen interest is the type or system of byproduct oven which is best suited for accomplishing this. Mr. Blauvelt very clearly points out what the requirements of the horizontal type of oven are for this purpose, and he shows that simplicity and perfection of uniform heating are the two main requisites.

The new Semet-Solvay horizontal-flue regenerative oven described by him is one of the latest types of byproduct oven constructed to meet the conditions in this country. It naturally differs materially from the latest type of vertical-flue oven now in successful operation in the United States. The oven described by Mr. Blauvelt represents the successive and progressive steps made by the Semet-Solvay Co. in strength, simplicity and effort for uniform temperature.

Oven Types and Coking Time

Much has been said in favor of simplicity of recuperation as against regeneration for the combustion of the gas in the flues, also of continuous heating versus reversing; but, all told, all modern types have finally found it to be more economical and efficient to use regeneration in place of recuperation, except in certain isolated cases, as pointed out by Mr. Blauvelt. Unless great care is taken in design, it is almost impossible to prevent short-circuiting or leakage of gas and air in recuperative chambers or flues and this is not only wasteful, but impairs, to a certain extent, the efficiency and the control of combustion.

The strength of construction in this latest type of Semet-Solvay oven is a noteworthy feature of great importance, for strength of oven and flue walls is imperative in our modern coke-oven practice of fast driving necessitated by short coking time. The simplicity of control of gas and air and the ready supervision of the combustion in the flues by means of peep-holes are factors that will appeal to all coke-oven operators.

As to coking time, I regret we have no definite data from Mr. Blauvelt, for this is a point of great importance to us. We have found, as a rule, that the shorter coking time gives the best blast-furnace coke and that there must

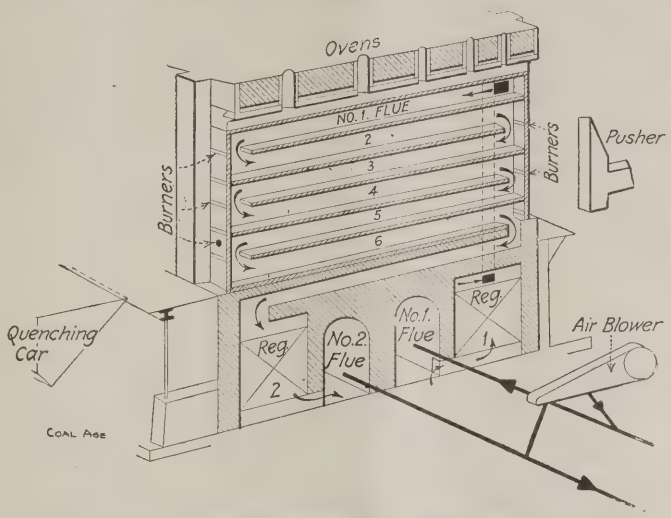

Fig. 4. The Arrangements of the Semet-Solvay Oven

be no delay in pushing the coke out of the oven after it is coked. What the actual length of coking time for various coals alone or in mixture is, has to be determined by actual trial; so far, we find that there is no great difference in coking time in the type of oven with which I am most familiar, whether we use high- or low-volatile coals. It may be found advisable to increase the coking time somewhat when using all high-volatile coals, but the difference between this and low-volatile mixtures does not, in our present experience, exceed, say, two hours on the average.

In view of its ability to obtain high and uniform coking temperatures, I can see no reason why the new Semet-Solvay coke oven should not be able to make coke in practically the same time as that of any other system. All in all, this latest development is of keen interest to us, as it is the purpose of the company with which I am connected, the United States Steel Corporation, to adopt always the latest and most approved type of byproduct coke oven, being in no sense whatever tied down to any one system by preference, prejudice or any other reason.

Some English coal figures were supplied to the Nottingham Society of Engineers by W. Bardill. Whereas the coal output in 1860 was 80 million tons per annum, in 1911 it was 270 million tons. Forty years ago, an output at a colliery of 500 tons a day was regarded as heavy indeed, but today, at many collieries, they raise 3500 tons per diem. This marvelous development was attributed to the increased use and adaptation of mechanical appliances by mining engineers.

The Labor Situation

SYNOPSIS—The Ohio situation is a deadlock, because the miners have bound themselves to make a contract with the eastern Ohio operators which would be wholly unfair to their employers. But some of the miners are disposed to withdraw concessions already offered, returning to their former demand for 49.64c. per ton of machine-mined, run-of-mine coal. In Colorado, President Wilson has suggested a form of agreement which seems more acceptable to the miners than to the operators.

Since the adjournment of the joint-scale committee in eastern Ohio on Sept. 4, there has been no reason to suspect that an agreement will come soon. In fact, the position of the miners has been considerably strengthened by the approaching solution of the difficulties in Colorado, and by the rehabilitation of union funds, now that the Vancouver and West Virginia troubles are ended. The expectation that all the resources of the union will now be diverted into eastern Ohio fills the miners on strike with the keenest of satisfaction. It is as if Germany and Austria were to make peace with all nations but France. Such a consummation would fill Germany with assurance and France with gloom. The position of the eastern Ohio operators is not less harassing than would be the position of the French republic under such circumstances.

A Fair Proposition

The operators have offered a new compromise on the run-of-mine law. They have offered to pay for slack, but not at the lump-coal price. They will give 58c. for lump coal and 22c. for slack, and it must be conceded that the offer is equitable and shows that the operators are now prepared to accept an exact equivalent, provided that their interests are protected by a scale which will reward the miners for care in handling their coal.

The proportion of coal which is not slack is 64 per cent. The equivalent rate to that formerly obtaining, namely, 69½c., should be 64 × 69½, or 44.48c. But if 64 per cent., the lump coal proportion, is paid for at a rate of 58c., 37.12c. per ton mined will be realized for the lump coal. If 36 per cent., the slack portion, is paid for at 22c. per ton, then 7.92c. per ton mined will be realized for the fine coal. Adding these together, we find that the miner will receive 45.04c. per ton, which is 0.56c. per ton more than an exact equivalent.

How any right-thinking man can turn down such an agreement is beyond comprehension. It is surely right to put a premium on the making of large coal, and to pay the miner for both kinds of fuel approximately on the basis of selling prices. By refusing this most reasonable offer, the miners of eastern Ohio have placed themselves in an unenviable position. Their only defense now is that they have made a promise to the operators in other parts of Ohio which they cannot break. Such a promise, which meant a reduction in wage in southern Ohio and an increase in eastern Ohio, should not have been made. Surely the miners in eastern Ohio should be allowed by the union to return to work at an increased wage, regardless of how small that increase may be. For everywhere else they have been counseled to return to work at unchanged wages except in the rest of Ohio, where wages are actually decreased.

Disposition to Return to Work

The men are really disposed to return to work in most cases at the offers made to them by the operators. The miners at the Pursglove mine at St. Clairsville are said to have held a meeting on the 9th and decided that they were willing to return on the 58-22 basis. But several out-of-town officers of the organization came around in the nick of time and prevented the men from acting. At Neff, where there has been much destitution, the prospect of winning the strike by a half-cent rise and a recognition of the run-of-mine bill looks too good to the men to be passed up. It is stated that 270 men out of 300 on a local comprising the miners of the United States Coal Co., in Bradley, petitioned their representatives at the miners' and operators' conference to settle the strike on the best terms available. The petition was not read.

But Some Men Get Less Reasonable as Time Passes

But the sentiment is not all in one direction. On the 10th, 225 members of Local No. 1077 held a mass meeting and unanimously adopted a resolution calling, not for 47c., but for the original demand of 49.64c. for machine-mined run-of-mine coal. The local is composed of employees of the Rail & River mine in South Bellaire, and there are about 400 members in all. Local union No. 1666, of the Fort Pitt mine, opposite Moundsville, W. Va., discussed the same matter and urged that the demand for 49.64c. be renewed.

The Militia Wanted by the Miners

Another difficulty has arisen. The operators formerly employed union men to operate their pumps and fans. Recently they have called on their petty bosses to do that work. These men are nonunion employees, and the miners insist that the understanding with J. M. Roan, the mine commissioner, to the effect that only union men should be employed, be carried out. It is not clear whether these bosses, who are replacing the union pumpmen, engineers and repairmen, are monthly employees who are usually paid by the company whether the mines work or not. Some of the companies have let the mines be flooded and the air become stagnant rather than engage union men who are striking against them.

Local union No. 430, at McClainsville, west of Bellaire, passed a resolution requesting that troops be sent to Belmont County to compel the operators to reinstate the men thrown out of work by the employment of petty bosses. They have urged that the need for this work is just as urgent now as it was when the operators desired the militia for the protection of those nonunion men who were then doing the pumping and repairing.

There has been some expectation that the operators would introduce strike-breakers, but W. R. Woodford, president of the Pittsburgh Vein Operators' Association of Ohio, denies it without qualification. Benefits of $3 weekly will be paid from now on by the union, and now union activity elsewhere has ceased, a large amount of money will become available to back the eastern Ohio cause. This feature, and the miners' pledge for a 47c. rate, will be the sole causes for delayed settlement.

The operator is not unreasonable in eastern Ohio. He surely has outstripped all other operators by offering an increase in wage, however small. Even 44.61c. on a mine-run basis has been offered, and this is better for the miner than last year's scale.

The Coshocton Difficulties

In the Coshocton district, the scale has not yet been adjusted, but arrangements have been made for a conference in the near future to try to arrive at an adjustment. The difficulty in that district is not so much a matter of scale as the question of the payment of 5c. a ton to the men for pushing the mine cars from the neck of the room to the face and back again when loaded. It is believed the matter will be amicably adjusted.

Questions of the quantity of fine coal allowable under the mine-run law have generally been settled at the various mines without calling on the Ohio Industrial Commission.

Violence at Elverton

At Elverton, Fayette Co., W. Va., there has been a strike resulting in much violence. On the 10th of this month, several men were being lowered down a plane. Two loads of men were allowed to pass, but riflemen, declared to be strikers, fired at the men in the third car and killed one man who had lately arrived from Pittsburgh, Penn.

The shooting began at 4.30 p.m. and continued for 15 min. After the men had reached safety in shanties at the foot of the hill, the fire was directed on the company store, which also serves as the home of W. R. J. Zimmerman, the manager of the Branch Coal & Coke Co. The shooting was maintained at intervals till 5 o'clock, and fire was returned from the company store and office.

The dispute is about a check weighman whom the company refuses to recognize. The man is declared to be neither in the employ of the company nor a practical miner. The miners' officials and Gov. Hatfield, president of the board of conciliation, have tried to get the men back to work, leaving the dispute open till the governor has had time to render his decision. The men will not accede to this arrangement, though it follows the lines of their agreement. The company declares it will not reinstate four of the striking men. It has employed its own detectives and has refused to accept the assistance of the sheriff's officers. It is though that much trouble may result, and the subdistrict president, L. C. Rodgers, of the New River United Mine Workers, declares he is

endeavoring to prevent union men from compromising themselves by staying around the scene of the trouble.

No Reduction in Wage

From all quarters, we are assured that there is no truth in the story that there has been a decrease in the mining rate along the Norfolk & Western Ry. William Leckie, a large operator of Welch, W. Va., writes us that he has not heard of any such reduction in rate. N. H. Mannakee, civil and mining engineer, of Williamson, W. Va., also declares there has been no cut in that region. It has also been reported to us that inquiries have been made throughout the Pocahontas field, and no operation has been discovered at which any cut had been made.

The Mailed Fist

Some time ago we printed an editorial entitled "The Mailed Fist," condemning certain orders of the War Department, and learned later, apparently in contradiction of our statement, that the administration did not require men to be citizens of the state of Colorado before entering the service of Colorado coal corporations. Residence alone, we learned from the War Department, was required. We expect to publish a full record of the War Office orders which we have secured, and to add to it the letter of the War Office to us, in which the issue is carefully dodged. An order was issued on Aug. 14, 1914, requiring that all miners recently employed must be citizens of the state of Colorado. Afterward, this order was modified, and it is no longer in force.

The Colorado Armistice

President Wilson is endeavoring to arrange a three-year agreement between the Colorado operators and union miners. The latter have spent $3,000,000 on their strike, and are at their wits' end to secure the money for further finance, especially since the eastern Ohio situation has called for money in larger quantities in the hitherto peaceful states. The agreement, on which we expect to comment next week, is as follows:

There hereby is established a three-year truce, subject to:

1. The enforcement of the mining and labor laws of the state.
2. That all striking miners, who have not been found guilty of violation of the law, shall be given employment by the employer they formerly worked for, and where the place of the employee has been filled, he shall be given employment as a miner at the same or other mines of the company.
3. Intimidation of union or nonunion men strictly prohibited.
4. Current scale of wages, rules and regulations for each mine to be printed and posted.
5. Each mine to have a grievance committee to be selected by majority ballot at a meeting called for the purpose, in which all employees (except officials of the company) have the right to participate.

Members of said committee must be employed at least six months at the individual mine before being eligible.

Married men to be in the majority on each committee.

6. It is understood as a condition of the creation of said commission that during the life of the truce,

(a) The claim for contractual relations is to be waived, but this shall not prevent the voluntary agreement betweeen any employer and their employees during the life of this truce.

(b) No mine guards to be employed, but this does not preclude the employment of necessary watchmen.

(c) In the establishment of the truce, the presence of the federal or state troops should become unnecessary.

(d) There shall be no picketing, parading, colonizing or mass campaigning by representatives of any labor organization of miners that are parties to this truce, which will interfere with the working operations of any mine during the said period of three years.

(e) During said truce, the decisions of the commission in cases submitted shall be final and binding on employers and employees.

(f) There shall be no suspension of work pending the investigation and reaching a decision on any dispute.

(g) The suspension of a mine over six consecutive days by the company may be authorized for cause satisfactory to the commission, but not pending any dispute.

(h) Wilful violators on any of these conditions will be subject to such penalties as may be imposed by the commission.

The Miners Approve and Operators Question

The miners' convention on Sept. 16 voted to accept the proposals after a two-day debate, the vote being 83 in favor of the agreement and 8 against it. The Colorado mine operators held a meeting Sept. 19 and succeeding days, to prepare a reply to the President relative to the proposed agreement. A committee was formed to formulate a reply, consisting of J. C. Osgood, F. E. Gove, of the Victor-American Fuel Co., and D. W. Brown, of the Rocky Mountain Fuel Co.

The Colorado Fuel & Iron Co., through J. W. Welborn, its president, declares that it does not have room in its mines for all strikers not proved to be criminals. It has already almost as many men as it needs in the service. Mr. Welborn also declares that it is dangerous to employ men hostile to the company's purposes, at work as hazardous as coal mining. He states that, where there are vacancies he is willing to employ any strikers who have not been guilty of acts of violence or overt hostility.

He objects to the provision giving a commission the right to determine whether the company shall close its mines for more than six days at a time. He states that the needs of the market are best known to the company. He also declares that the assessment of fines would only be operative against the coal corporations, as the men could not be made to pay them. He is very willing to see that the mining laws are complied with, and says that they have always been observed by his company. He also adds that, in accordance with the proposal, he has already ordered a full publication of the rates of mining and regulations appertaining thereto.

At Last an Agreement Is Made in the Southwest

Districts 14, 21 and 25, comprising Kansas, Missouri, Arkansas and Oklahoma, held conventions in Kansas City, at which the joint interstate agreement was ratified with minor changes, and the agreements reached between the committees of operators and miners were also ratified with trifling modifications. The new contracts, which remain in force till July 31, 1916, make practically no change in the wage scales. The chief changes are in local matters affecting only the particular districts.

The most important matter of the present contract and interstate agreement is that as to arbitrators. All disputes reach finally, under the new plan, a board of arbitration or district joint board, which is supposed to settle grievances without strikes or stoppage of work. This board consists of three members from the miners and three from the operators. There is to be a joint board in each district, but there will be two such boards in District 21, one for Arkansas and one for Oklahoma.

The officials of the districts and of the conference are this week going over the agreements and conferences carefully preparatory to their f rmal publication.

The boards appointed are as follows:

Kansas, District 14—Operators: George Richardson, commissioner; Ira Clemens, John Mayer. Miners: Bernard Harrogan, district president; Francis McDonald, James James.

Oklahoma, District 21—Operators: E. W. Hogan, commissioner; Dan McAlpine, James Cameron. Miners: Edward Cunningham, district president; Pete Hanraty, Ben Brown.

Arkansas, District 21—Operators: E. W. Hogan, commissioner; William McKinley, M. M. McWilliams. Miners: Edward Cunningham, district president; Peter Stewart, Robert Kendrick.

Missouri, District 25—Operators: W. L. A. Johnson, commissioner; William Harkes, B. T. Whitey. Miners: George Manuel, district president; B. C. Morrow, Charles Daither.

The Bache-Denman Coal Co. Approves the Check-Off

It is interesting to see that the Bache-Denman Co. is now using the check-off as a weapon to collect money from the Arkansas union for the riot and arson of the members of that organization at the Bache-Denman mines. Judge Frank A. Youmans has attached the funds of the Union in a dozen banks of western Arkansas at the suit of the Bache-Denman Coal Co., and the miners are not desirous of collecting the check-off if the money thus collected is to be lost to them by being applied to pay for the losses due to their lawlessness. It will take a long time for the Arkansas union to collect $1,250,000, and the men threaten to strike on general principles. Evidently such a strike can only be called for the purpose of influencing the court against continuing to attach the money of the union.

Our Front Cover This Week

The interesting photos shown on the front cover of COAL AGE, this issue, were furnished us by the General Electric Co. The two locomotives shown in the pictures are of "G. E." manufacture, the one operating in Kentucky being a 5-ton machine. Locomotives of this type are now being used for long hauls on the surface, as well as underground.

Mine Foreman Association Meet

In our issue of Sept. 5 we stated that the Knoxville field day was to be held on Oct. 15. This should have read Oct. 24. A number of teams are to compete for some nice prizes. The event is under the auspices of the Mine Foreman Association.

The Export Trade

A British View of Our Possibilities in the South American Trade

The *Colliery Guardian* (London, England) has the following to say regarding our attempt to break into the South American coal markets:

If this country is in a position to detach a large portion of Germany's foreign trade at the present time, it should not be forgotten that the United States, free from most of the difficulties that beset us, cherishes hopes also of benefiting from the embroilment of Europe. Amongst other ambitions, the desire to popularize Pennsylvania and West Virginia coal in South America is prominent. It is highly probable that efforts will be made to introduce American coal in other markets, but the Argentine Republic and Brazil naturally present themselves as those which, *a fortiori,* are most vulnerable to attack.

The matter, however, is not so simple as it looks. In the first place there is the difficulty that the United States has few ships adapted for this trade. The Ship Registry Bill, which has just passed through the American Senate, seeks to provide a remedy. The Bill admits to registry in the United States foreign-built ships when owned by citizens of the United States or corporations organized under the laws of the United States or of any state; but it excludes such vessels from engaging in the coastwise trade.

A section of the Senate Bill also authorizes the President to suspend the laws requiring watch officers on such vessels to be citizens of the United States whenever, in his judgment, there are not enough citizens of the United States available and qualified to fill such positions. The bill also authorizes the President in his discretion to suspend the "provisions of the law requiring survey, inspection and measurement by officers of the United States of foreign-built vessels admitted to American registry under the Act."

We can contemplate but little advantage to our American cousins on this score. The guerilla warfare of the "Dresden" and other German cruisers in the Atlantic must soon come to an end from lack of fuel alone, and insurance will add but little to the cost of freight.

On the other hand, our ships have the advantage of a return freight, which is not available to United States shipping, and exporters are strongly entrenched in South America. The bulk of the import trade in coal is in the hands of British exporters, who may be trusted to lose no opportunity of maintaining and extending their province. Of course, it is possible that South American shipping may be called into action. Brazil, Argentine, Chile and Peru own about 622 ships, with a combined gross tonnage of 204,473 tons.

But another greater difficulty that meets the American coal operator is the long credit system which prevails in the Southern Continent. The American shipper is not accustomed to the c.i.f. basis. . . It is true that in several cases since the war broke out buyers of British coal, who usually deal on a c.i.f. basis, have consented to clear the freight themselves so as to accommodate the exporter, who still has enormous sums outstanding to his credit, but it is certain that, if we are to continue business, a purely cash system of trading all around is out of the question.

It is important to remember that such coals as those of Pocahontas and New River, and some of the Pennsylvania and West Virginia gas coals, are but little inferior to the best that we can supply. It is an open secret that some of the largest firms of British coal exporters have been heavy buyers of American steam coals during the last year or two. Our impression is that if American coals do reach South America in any quantities, it will be through the agency of these houses. The markets, it may be added in conclusion, are most valuable, and the actual tonnage of coal, which exceeds six million tons per annum, does not by any means represent the whole of this value, for the connection with South America, in which coal forms one link, is of national importance.

A factor that must not be overlooked is the opening of the Panama Canal, which facilitates the transport of American coals to Chile, Peru and Bolivia, at present extensive customers for British and Australian coals.

The U. S. Geological Survey on the Export Question

The exports of coal from the United States have never been large enough to affect the production materially. They amounted to 20,000,000 short tons in 1912 and 23,200,000 tons in 1913, or less than 4 per cent. of the total output of the mines in each of those years. At present, however, while the six European nations that rank next to the United States as coal-mining countries are at war, the demand for export coal from neutral countries is inevitable.

It must be granted that the sale of manufactured products for export is preferable to the sale of raw materials, but there appears now to be a large opportunity for coal export that will not curtail in the least either the domestic supply of coal or the activities of domestic manufacturers. The exportation of coal to South American countries must be of advantage both in establishing trade relations and in insuring a balance of trade in our favor. Already shipments to European and South American ports have begun, and there is demand for authoritative information regarding the quality of the coal from the different fields accessible to the seaboard. How this information can be obtained has already been mentioned on page 9.

Our Coal Reserves

As stated by Secretary Lane, "Coal is our one resource about which there need be no present anxiety." In 1908,

Note—Abstract from "Our Mineral Reserves," U. S. Geolo. Survey Bulletin No. 599.

Campbell estimated that our reserves of easily accessible anthracite and bituminous coal were more than eleven hundred billion (1,166,527,000,000) tons and that nearly half as much more of the same grades was accessible with difficulty, besides comparable tonnages of sub-bituminous coal and lignite. Five years later a new estimate made by the same geologist, in the light of much better geologic data, especially regarding the extent of the Rocky Mountain coal fields, exceeded these figures by nearly 30 per cent. His estimate of more than 15 hundred billion (1,500,000,000,000) short tons in the United States, exclusive of Alaska, was published in a volume on the world's coal resources resulting from an international inquiry made by the Twelfth International Geological Congress. This publication, in preparing which the geological surveys of the world coöperated, furnished the first authoritative statement of the coal supply of the world, and showed that North America possesses nearly two-thirds of this supply and that the United States alone has reserves exceeding those of any other continent and nearly double those of Europe.

In view of the steadily increasing consumption of coal in the United States the question how long the exportation of coal should be encouraged or continued must be considered at some future time, for it will plainly not be wise to deplete too greatly this reserve of fuel, on which the Nation's industrial life must depend. At present, however, the question of the duration of our coal supply includes so many indeterminate factors that any prophecy as to the date of its exhaustion must be of doubtful value, and it does not now seem at all improvident for us to utilize in some degree this abundant resource as a means of building up our foreign commerce and making new markets for the products of our industries.

Until the present war broke out, Great Britain was the only country that exported coal in considerable quantity, but Great Britain is already beginning to feel the pinch of poverty in her coal supplies, and it is highly probable that when peace is once more established she will place restrictions upon her exports of coal. In 1913, the exports of coal from Great Britain amounted to 82,200,000 short tons, and the bunker trade called for 23,555,288 short tons more. In the same year the exports from the United States, as already stated, amounted to a little over 25,000,000 short tons and the total bunker trade at the principal ports—New York, Philadelphia, Baltimore and Hampton Roads—was only about 7,500,000 tons, indicating that most of the trans-Atlantic liners, the majority of which are English, have been carrying from the other side a sufficient quantity of coal for the round trip.

The high-grade steaming coals of the United States, which would be the ones in chief demand for export trade, are found largely in the eastern half of the Appalachian coal field, which includes the Clearfield, Allegheny, and Somerset districts of Pennsylvania on the north; the Cumberland region of Maryland; the Elk Garden, Fairmont, New River and Pocahontas districts of West Virginia; the southwestern counties of Virginia; the eastern counties of Kentucky and Tennessee; and the Birmingham and other districts of Alabama on the south. Of these coals, those available in highest quality are the semibituminous coals of the Pocahontas, New River, Elk Garden, and Cumberland districts and the better grades of Clearfield. The fields nearest the seaboard are those of the Cumberland and Elk Garden districts, but these are approaching exhaustion, so that the advantage in this respect will fall to the Alabama mines, which are being made more easily and cheaply accessible by the slackwater improvements in Warrior River, which have already resulted in a marked advance of Mobile as a shipping port.

United States Almost Independent in Mineral Resources

Probably no other nation in the world so nearly approaches absolute independence in respect to mineral resources as the United States.

A glance at the statistics of mineral imports affords a means of comprehending in a broad way how great and complex is the task of attaining national independence in the mining, metallurgical, and chemical industries. Last year the imports of mineral products, both crude and manufactured, exceeded $270,000,000. Of this total probably $200,000,000 represents raw materials and crude metals, the value of these imports being about 8 per cent. of that of the domestic output.

In this list of imports the larger items named in the order of value are unmanufactured copper, precious stones, nitrate of soda, copper ore and matte, nickel, tin, iron ore, pig iron and steel, petroleum products, manganese ores and alloys, platinum, aluminum, pyrite, graphite, stone, potash, and magnesite.

This country has an abundant supply of most of these mineral products that are now imported in large amounts, and as to them it can be independent of foreign countries. The only essential minerals of the first rank of which the United States has no known supply at all commensurate with its needs are nitrates, potash salts, tin, nickel and platinum, the list thus comprising two essential mineral fertilizers and three useful metals.

The Coal Markets of Cuba

Coal contracts for the large consumers in Cuba as a general rule are made in the autumn of each year, and are affairs of many years standing. The three largest consumers of coal in the Island of Cuba are: The United Railways of Havana and allied lines; the Cuba R.R., Camaguey, Cuba; and the Havana Electric Railway, Light and Power Co. In addition to these, the sugar mills and mining companies of the island consume large quantities. A complete list of these appears in the Cuban section of the World's Trade Directory, issued by the Bureau of Foreign and Domestic Commerce, Department of Commerce, Washington.

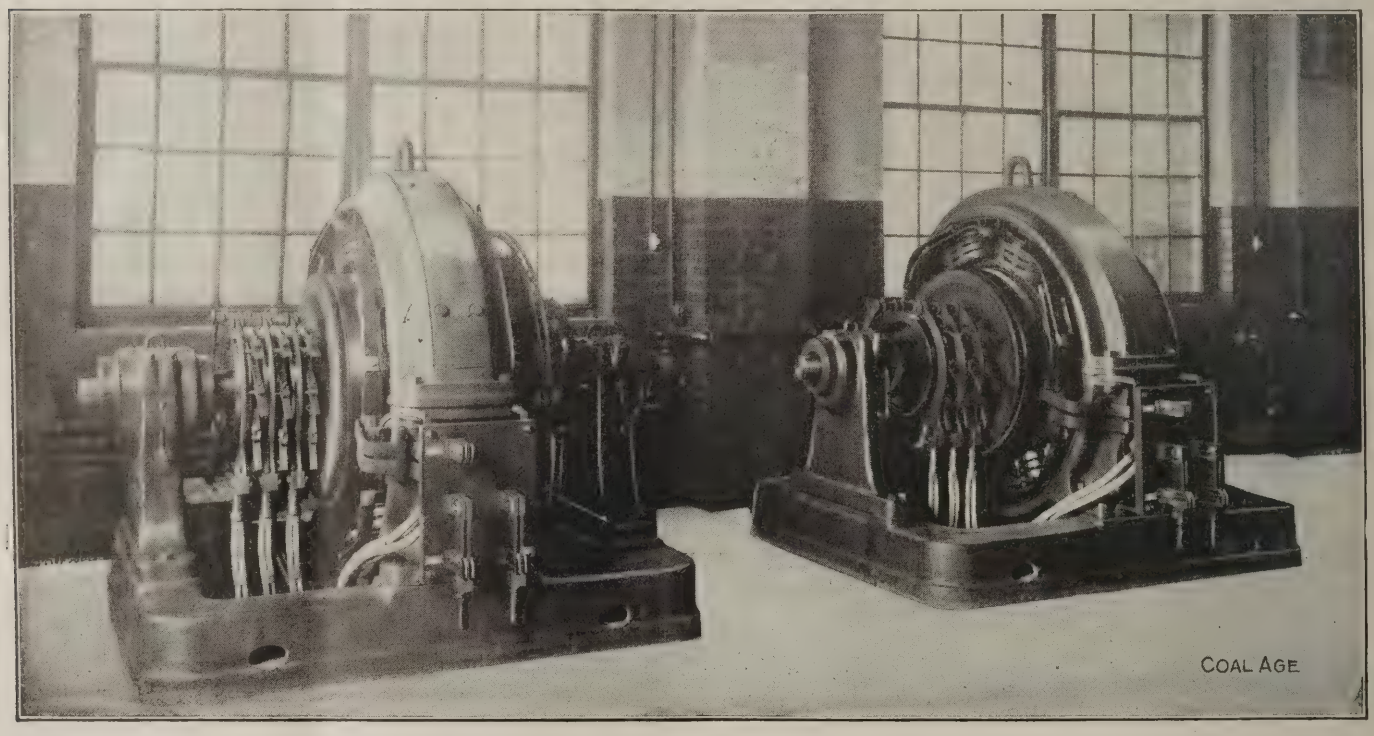
The largest importers of coal in Cuba for retail purposes, that is, for ship's use, are the Havana Coal Co. (E. J. Berwind & Co.) and the West Indies Coal Co. The first named, having an extensive plant in Havana for loading and unloading, has almost a monopoly of the business.

One horsepower-hour is equivalent to 2545 B.t.u. per In a pound of Pocahontas or other coal containing 15,000 B.t.u., there is enough energy, could it all be utilized, to supply almost 5.9 hp.-hr. or to raise a weight of one pound 2210 miles against the force of gravity. This energy would lift a 100-ton locomotive 58 ft.

Power Department

The Operation of Rotary Converters at Coal Mines

By C. A. Tupper*



SYNOPSIS—A rotary converter is virtually a synchronous motor-generator set with the frame, field and armature windings common to both elements of the unit. This hybrid among electrical machines must be brought into synchronism with the source of supply before being loaded.

In previous articles, methods of installing and operating generators and motors, both for alternating and continuous current, have been described. These pertain to complete systems, either of the one or the other, while possible links between the two were not considered.

changers have been developed. These are known as the motor generator and the rotary converter. Each is best suited to some particular kind of work, and the choice will depend upon the engineering and economic considerations entering into the problem.

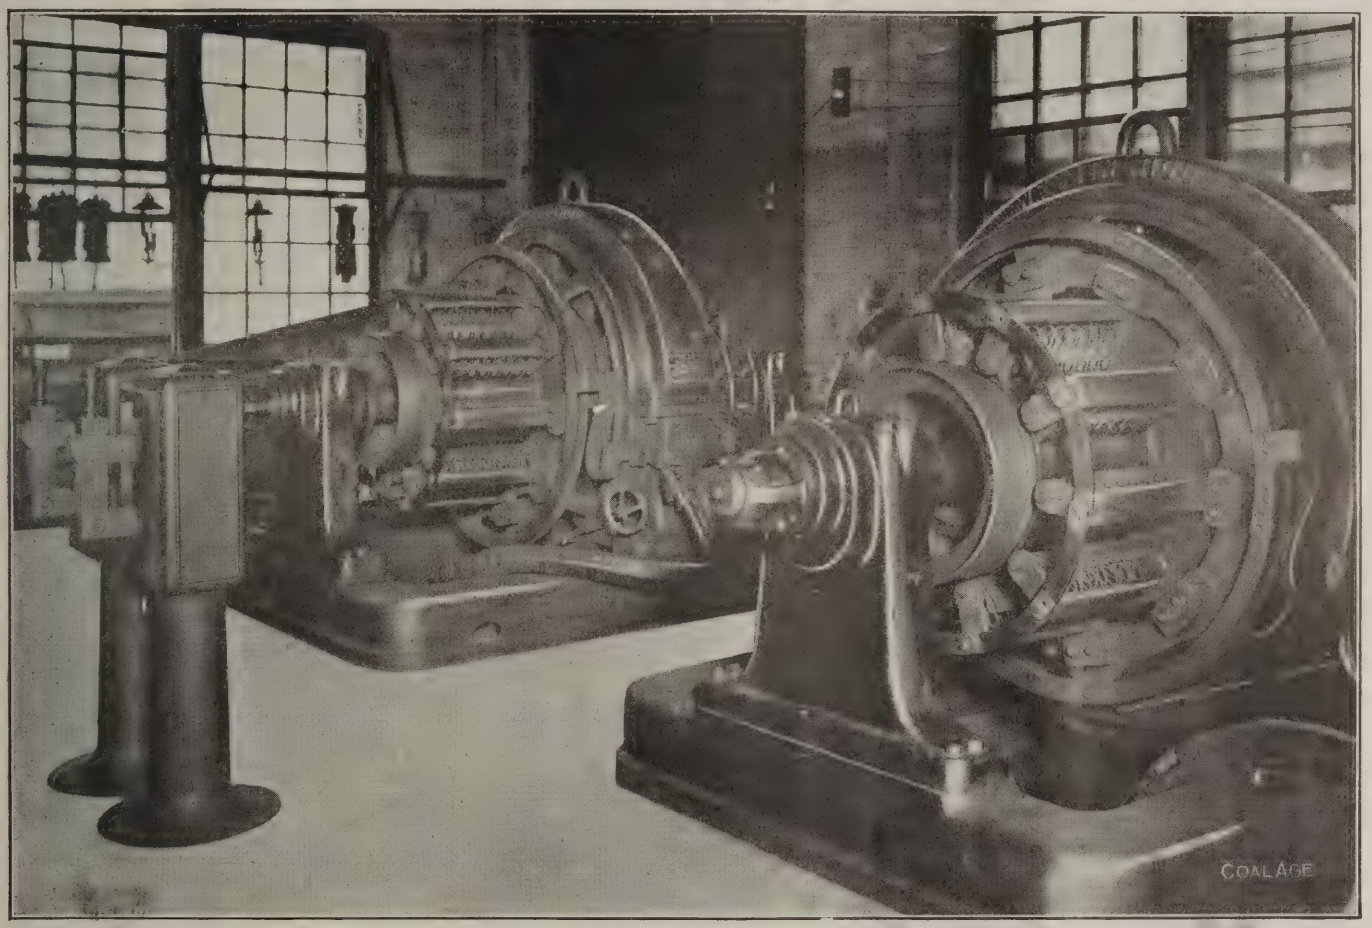
The rotary converter has usually the advantage over the motor-generator set in point of cost, there being but one machine instead of two, and also in respect to efficiency, as both the mechanical and electrical losses are naturally less. In practice, the use of the rotary converter is usually limited to substations from which direct current is distributed, in amounts of 100 to 200 kw. upward; but for this purpose in coal-mining service, it is particularly well adapted. The ordinary installation consists of 300- to 500-kw. machines.

The use of the rotary converter in coal mining is a

Two 300-Kw. Rotary Converters. Six of These Machines Have Been Installed by the Virginia Pocahontas Coal Co. at Coalwood and Juno, W. Va.

While, however, the tendency at present, in plants of any size, is to generate and transmit power, even over short distances, as alternating current, the use of continuous-current motors has so far retained its place for certain purposes, as, for instance, coal-cutting machines, underground haulage, electric hoists, surface tramming, or otherwise where variable-speed drive is required, that a considerable proportion of the power generated is still applied through motors operating on such current.

To make possible the use of the two systems in connection with each other, without going to the expense of separate generating plants, two principal types of current



good illustration of the utility of "borrowing" ideas from other lines of industry. It first became prominent in electric-railway, commercial-power and lighting service; then it was taken up in various industrial systems operated partially on direct or continuous current; and from these reached the collieries and finally spread into other fields of mining.

A simple explanation of the rotary converter, which will aid the reader in applying to it many of the rules for installation and care previously given, without repetition in this article, is to regard it as developed in several successive steps.

Taking the synchronous motor-generator set, with its synchronous motor and continuous-current generator, as-

*2172 East 89th St., Cleveland, Ohio.

sume that the two armatures are brought side by side on the main shaft, under a single inclosing circle of field coils. Then observe the further simplification which results from placing the two armature windings on the same drum, and finally consider the effect of connecting the two armature windings or using the same winding for both machines. An idea is now obtained of the conditions which exist in the rotary converter. It has been aptly described as a direct-current machine to which slip rings, connected to suitable points on the armature, have been added.

Rotary Converters for Large Coal-Mining Operation, Run in Parallel to Equalize Load or Boost Power Factor

The direct-current voltage of a motor-generator set is independent of that of the supply circuit and can be adjusted as may be desired; but the continuous-current potential delivered by the rotary converter depends upon and is fixed by the electromotive force of the alternating current received through the slip rings, necessitating, in the case of high-voltage transmission, the insertion of a step-down transformer on the alternating-current side.

On a three-phase machine, which is the most common type, the alternating-current voltage is usually about 61 to 62½ per cent. of the continuous-current potential. The same is true of double-delta-connected six-phase rotary converters. For single-phase, two-phase and diametrically connected six-phase converters, the alternating-current voltage is approximately 71 per cent. of that of the continuous current delivered.

Three Methods May Be Employed in Starting

There are three ways in which rotary converters can be started; and, as the alternating-current side of the machine is a synchronous motor, it must be brought into synchronism with the central-generating plant before the load is thrown onto the continuous-current side.

First Method—The machine can be started from the continuous-current side when it is connected to a general distribution system.

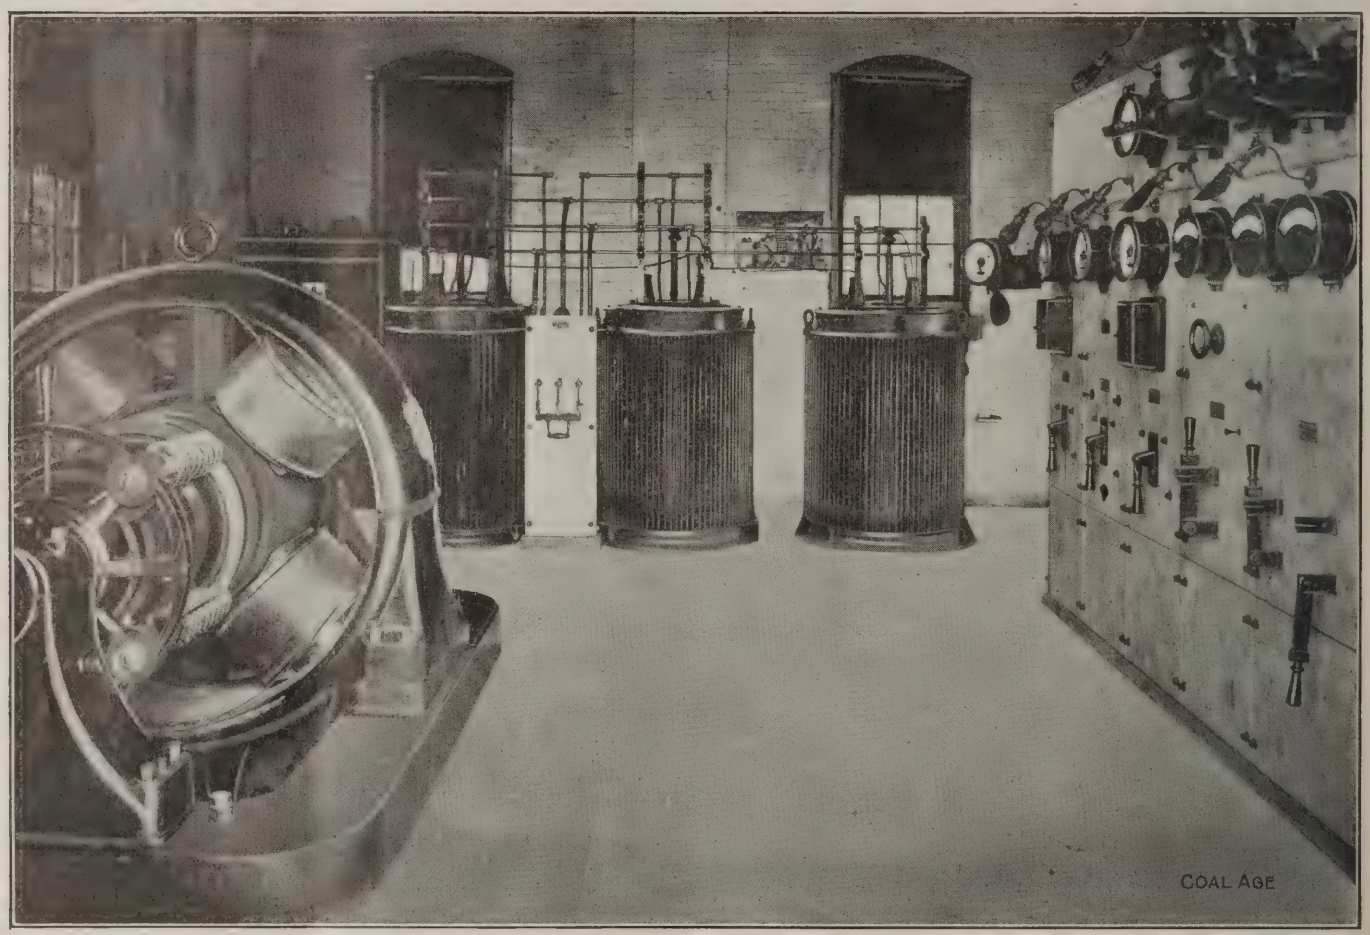
Second Method—It can be stated by means of a small induction motor, either belted or direct connected to the shaft.

Third Method—It can be started from the alternating-current side by supplying a reduced voltage to the slip rings, as in the case of induction or continuous-current motors.

This reduced voltage is usually obtained through taps on the transformers. When the machine is started by the third of these methods, the field must be broken. This method has this advantage, that the rotary converter automatically falls into synchronism. It will, therefore, be considered first here.

The starting voltage required varies somewhat for the different sizes of rotary converters. It is standard practice in mining, however, to provide one starting voltage only and to make this approximately one-third of the operating voltage on the alternating-current side; but, for the larger sizes of converters and under certain local conditions for which expert advice will be required, it is sometimes desirable to use two starting voltages, approximately one-third and two-thirds of the normal operating potential.

After a rotary converter has been installed and dried out, according to the methods dictated by good practice for *both* alternating- and continuous-current machines, the entire unit should be subjected to a thorough final inspection, to make sure that it is ready for starting. The brushes on the continuous-current side, for example, must be sound and free from chipping, should move freely in the brush-holders and be properly adjusted to the commutator and also be set in the right position with reference to the neutral line. The alternating-current brushes will also need to be adjusted for good contact without cutting the slip rings too rapidly.



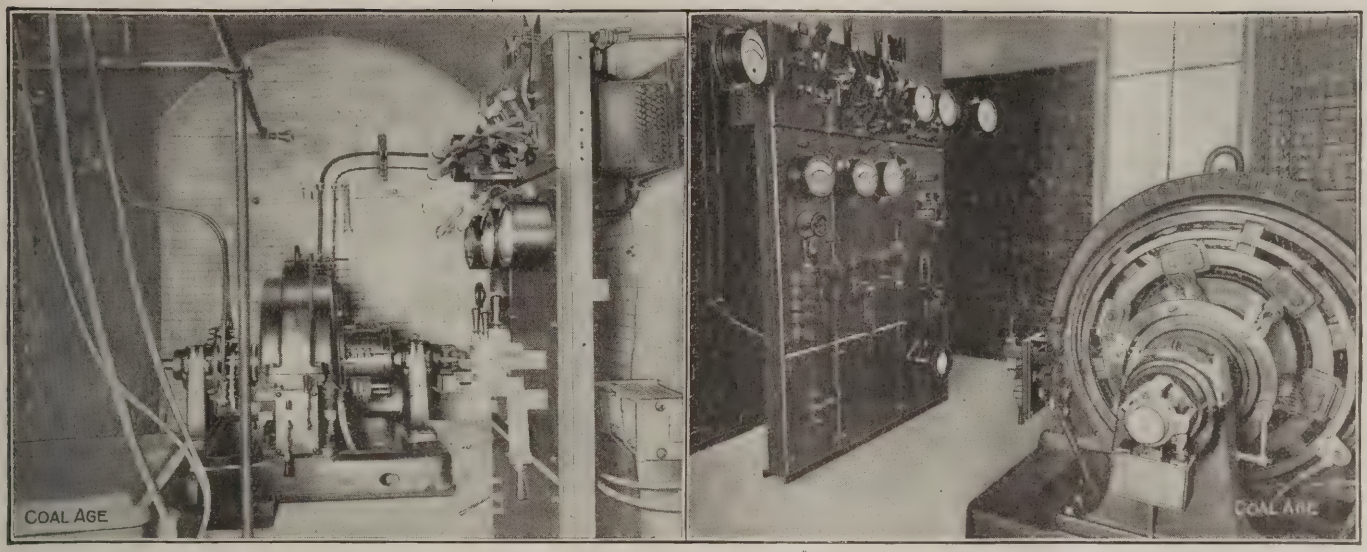
It will then be well to examine the interior surfaces of the unit, to see that no foreign material has become lodged in it, particularly tools or broken brush carbons, and to be certain that the insulation, especially on the ends of the armature windings, is intact.

Examination of the bearing housings, to make sure that there is plenty of oil in the wells and that the rings are free to turn, should not be omitted.

The Switches Should Be Examined

Finally, the various switches should be inspected, to insure that no one has tampered with them. Above all things, the field break-up switch must be open. If this happens to be closed during starting, a dangerous voltage is certain to be developed. The speed-limit switch must also be open and in good condition, with contacts clean and the spring operative. Furthermore, all knife switches on the switchboard connected with the operation of the rotary converter, as well as on the starting panel, on the pedestals if used there, and on the rotary converter frame for both the alternating- and continuous-current circuits, should be *open*.

Assuming, then, that we are to start the unit from the alternating-current side, at one-third voltage, the following directions will govern. These are based on the operation of a Westinghouse machine but are applicable to any other make, so far as the apparatus mentioned is used in the plant. Any differences in this respect can be readily detected and the procedure altered accordingly. When in doubt, get expert advice.



A Thoroughly Modern Type of Mining Substation at the York Run (Penn.) Plant of the H. C. Frick Coke Co. The Converter Is a Three-Phase, 25-Cycle, 344-355-Volt Machine

The rotary converter about to be started, with a single reduced voltage applied on the alternating-current side, is, say, a 3-phase, 60-cycle machine, delivering continuous current for coal-mining service at 250 volts. Its normal speed will be 1200 revolutions per minute.

The preliminary conditions having been complied with, close the oil circuit-breaker on the high-tension side of the transformer and insert the plug for the continuous-current voltmeter. Put the double-throw starting switch up to the starting position; then, when the voltmeter above mentioned indicates the correct polarity, close the field break-up switch in the "down" position, so as to have the rheostat in the field circuit.

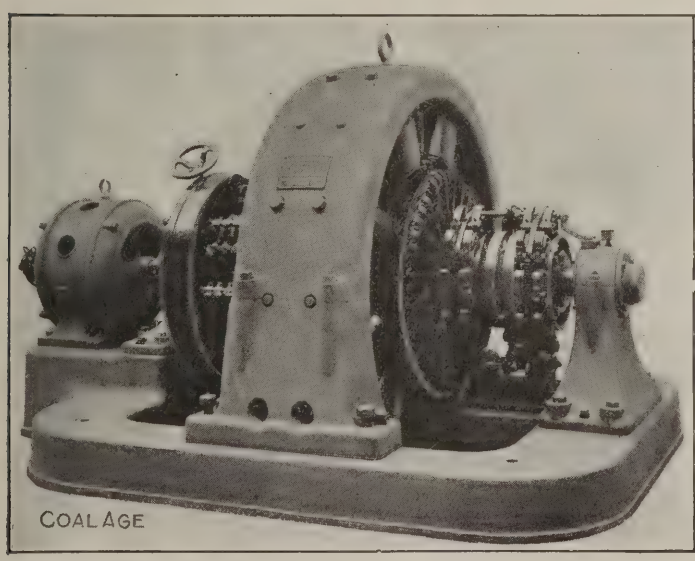
As soon as the voltmeter indicates reversal of polarity, close the field break-up switch in the upper position, thus reversing the shunt field and connecting it directly across

A 500-Kw., 60-Cycle, 600-Volt and a 150-Kw., 60-Cycle, 250-Volt Rotary Converter. Both These Machines Are Installed in Colorado Coal Mines

the armature. The indicator of the voltmeter will swing back toward zero. When it reaches that point, throw the field break-up switch again to the lower position.

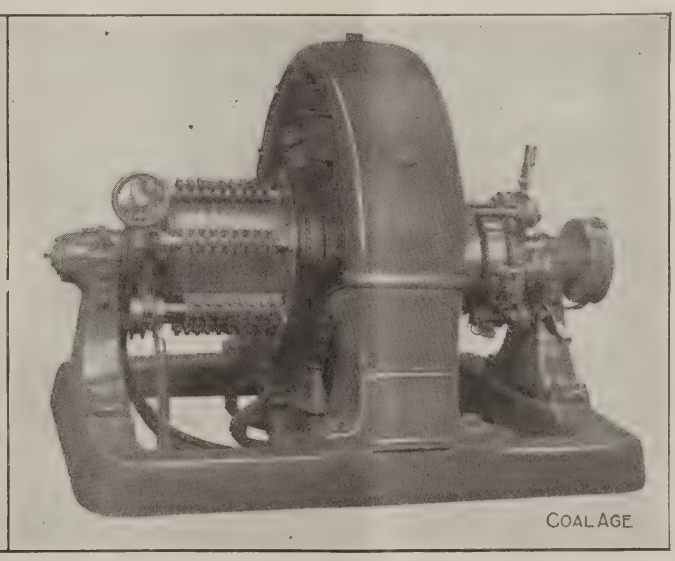
The unit should come up to synchronous speed in about 30 sec., and lock into step, indicating this condition by a steady current on the alternating side and a steady deflection of the continuous-current voltmeter.

If the voltage comes up with the right polarity, showing that the unit is up to synchronous speed, throw the starting switch down to the running position. If, however, the machine fails to slip a pole and the voltage again comes up with reversed polarity, it is evident that the field induced by the alternating current in the armature is too strong. The starting switch should accordingly be opened momentarily, to permit the machine to slow down somewhat, and closed again in the up position to proceed as before.



With the rotary converter properly running, adjust the continuous-current voltage to the proper value. Means of varying the voltage, which differ according to the character of the installation, will be referred to later.

If there is a series shunt, close the switch for that circuit, then the continuous-current circuit-breaker, then the equalizer, negative and positive switches. When operating two or more machines in parallel, adjust the field rheostats so as to equalize the load. Finally, make another examination of the bearings to see that the rings are turning and carrying plenty of oil.

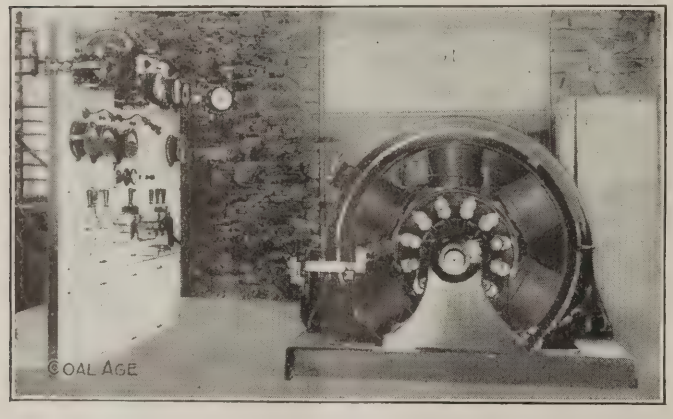


Larger Machines Have Two Starting Voltages

Where two starting voltages are applied, in the case of the larger machines, the procedure will differ in few particulars from that given above; but there will, of course, be two starting switches to handle. At the beginning, both should be thrown *up* to the starting position, and then the switch connected to the low-voltage tap on the transformer closed to the second starting position.

The time elapsing between these two operations should be such that the swing of the ammeter, when the second voltage is applied, will not exceed that caused by the first starting voltage. This time varies somewhat with machines of different capacities and can best be determined

A 250-Kw., 6-Phase, 50-Cycle, 480-Volt, English Rotary Converter with Starting Motor



A Standard American Rotary Converter for Coal-Mine Service

by practice. When the rotary converter is up to synchronous speed, the second starting switch should be thrown down to running position and the first starting switch opened. Adjustment of the continuous-current voltage follows, with the remaining course as before.

Induction Motors Are Sometimes Used in Starting

In practice, it is not unusual to employ a small induction motor to start a rotary converter and bring it up to speed and synchronism with the supply circuit. No separate exciter is necessary, as the converter itself, when put in motion, furnishes continuous current from the commutator. The method of starting is as follows:

First, see that the resistance of the rheostat is all cut in on the field circuit, that the knife switches on the alternating-current side are open and that the oil circuit-breaker on the high-tension side of the transformer is closed, also that the plug for the continuous-current volt-

A 200-Kw., 25-Cycle, 250-Volt, Rotary Converter of the McKell Coal & Coke Co., Sydney, W. Va.

meter and the synchronizing plug are inserted. Then start the induction motor, and thereby the rotary converter, by closing the knife switch controlling the former. Build up the continuous-current voltage to approximately that of the line by adjusting the field rheostat, and slow down the rotary converter to synchronous speed by closing the switch controlling the synchronizing resistance. If the speed becomes too low, open and close the switch until it gets to the point desired.

When the lamps or synchroscope indicate synchronism, connect the rotary converter with the supply circuit on the alternating-current side, by closing the switch or switches—there being two in the case of six-phase double-delta connection—and open those controlling the starting motor and synchronizing resistance. Adjust the field rheostat to obtain the minimum current in the alternating-current circuit, and then proceed as above recommended for self-starting.

As will be gathered from the foregoing, this auxiliary induction motor is wound for a speed slightly in excess of that for which the rotary converter is designed, and the method above outlined simply means that the latter is brought down to synchronous speed by loading one of the phases through a suitable rheostat. This method makes the process of synchronizing exceedingly simple, and, as the power developed by the induction motor need only be about one-tenth of the full load output of the rotary converter, the additional cost for its installation should not be excessive.

Self-Starting Is Adaptable to Large Sizes

Of the methods described, self-starting from the alternating-current side would seem to be best adapted only to the smaller sizes of machines, say 300 kw. and under, while a starting motor has been generally thought advisable for the larger units. In practice, however, self-starting has become practicable for even the largest machines and is now common. The chief objection to it, originally, was the rush of current from the supply mains, amounting to about three times the normal full-load consumption of the rotary converter, and, since this current was much out of phase with the supply pressure, the regulation of the entire system was seriously affected. The method outlined above, which insures that, before switching on the supply, adequate provision is made for reducing the voltage across the slip rings by taking intermediate tappings from the low-tension side of the step-down transformer, has overcome that difficulty.

Starting from the Direct-Current Side

Where there is connection to an independent supply of continuous current, say the exciter system of the main generating plant, any rotary converter can be started from the commutator side. This is a simple matter, and the method is similar to that used for an ordinary shunt-wound or compound-wound continuous-current motor.

The rotary converter is then synchronized by varying the field excitation until the correct speed, as indicated by the lamps or synchroscope, is obtained, when the switches on the alternating side can be closed, making the connection to the supply circuit. If the latter is 3-phase, it is usual to close one of the switches first; and then, at the moment when synchronism has been attained, the other two are thrown in.

In cases of emergency it is possible—although never advisable when it can be avoided—to omit the process of synchronizing. The rotary converter will then be run up to a speed slightly above synchronism, as when started by an induction motor, the continuous-current switches opened and the alternating-current switches immediately closed to make the connection to the supply circuit. The machine will pull itself into step and as soon as that has been accomplished the switches on the continuous-current side can again be closed.

It should also be stated that, although the rotary converter has thus far been considered in this article as taking the supply from an alternating-current system and transforming it to continuous current, the machine is readily reversible and can be supplied with continuous current at the brushes, in which case it will give out alternating current at the slip rings. Thus, if there are independent alternating- and continuous-current generating systems, the rotary converter can be made a load balancer between the two.

When, however, a rotary converter is feeding into an alternating-current system and running in parallel with synchronous generators, some difficulties may arise, due to the absence of armature reaction in the machine. In that respect, it differs materially from a synchronous generator or motor. Lagging currents on the alternating side will, therefore, tend to weaken the field and produce a condition of instability which may cause a falling out of step. This, however, can be overcome by special methods of field excitation.

For ordinary operation, in supplying direct current,

this absence of armature reaction—or the fact that it is practically negligible—is an important advantage; for, with a fluctuating power load, the pull on the machine can be varied enormously. Instances are recorded of temporary overloads in excess of 300 per cent. of the regular load, and the carrying of 100 per cent. overload for considerable periods.

Interpole Motors for Mine Locomotives

By A. R. Anderson*

On May 9, 1914, I presented an article in the Coal Age on "Interpole Motors for Mine Locomotives," which has been criticised in the Sept. 19, 1914, issue of the same magazine by Messrs. R. E. Hellmund and W. A. Clark, who do not see fit to agree with the views expressed in the original paper.

Of course, it was not expected at the time this paper was written, that it would meet with the approval of all readers, neither was it expected that any argument such as that presented could convince anybody whose experience with noninterpole motors was so entirely unsatisfactory as the experience of these two gentlemen evidently has been. I am not surprised that those whose experience with noninterpole motors leads them to say "the absence of interpolees and consequent poor commutation" should thus vigorously advocate the use of interpoles.

The experience of the writer, however, and the comments which he has heard made by practical men in the coal-mining industry stand in marked contrast to the evident experience of these two gentlemen. In fact it was the observation of the generally excellent commutation of properly designed noninterpole mine-locomotive motors, and the polished condition of the commutators of such machines, especially where ball bearings were used, that prompted the writing of the first article.

Even further, the writer's experience has extended to noninterpole motors of the same general design and a comparison between the commutation of interpole and noninterpole motors left the impression that the application of interpoles was labor lost. Of course, the commutation with interpolees was excellent; so it was with no interpoles, and it was on such observations as these that the original paper and arguments contained therein were based. I am sure that had the gentlemen who criticized this paper had the opportunity of seeing as much of good noninterpole motors as the writer has had, they could not conscientiously have given utterancee to the phrase, "the absence of interpoles and consequent poor commutation."

It is the privilege of any manufacturer of mine locomotive motors to build them either with or without interpoles as he may see fit, since there are no fundamental patents standing in the way. The original article on this subject was an attempt in a broad analysis of mine-locomotive motors and the conditions under which they worked, to show why nothing was to be gained by the application of the interpole motor over a properly designed noninterpole machine.

The statement made in the first article in regard to the horsepower rating of the machine, depending almost entirely upon the size of the motor carcass, will bear repeating:

"Motors of the railway type are totally inclosed; they are rated on the one-hour basis, and since there is practically no difference in efficiency between interpole and non-interpole motors, the amount of heat to be radiated for a given horsepower is practically the same in both cases and the dissipation of this heat within a given temperature rise requires a machine of practically the same size in both cases."

Thus the horsepower rating permissible on a motor of given dimensions, will be the same for both, whether interpole or noninterpole, and these dimensions generally permit of the design of a noninterpole machine with good commutation.

Keeping in mind that the subject under discussion is motors for *mine locomotives,* it is a little surprising that the gentlemen who criticized my article should submit a value of 40 per cent. for the coefficient of adhension under mine conditions. It may be possible under exceptionally favorable circumstancees to reach such a high value with soft tires, sharp, dry sand and a heavy rail, but it has been my experience that under actual mine conditions a coefficient of adhesion of 25 per cent., which is generally accepted for steel-tired wheeels, is very close to what is actually obtained.

It is only rarely that this coefficient of adhension is considerably exceeded. If it were possible to obtain such a coefficient greater than 25 per cent., the manufacturers would certainly take advantage of the higher rated draw-bar pull which this would place on their locomotives.

Another point then that will bear repeating is the statement that a properly designed mine locomotive can be and should be over-motored. For example, the Jeffrey Manufacturing Co. is building locomotives regularly, in which the motor capacity is such that at full normal rated load on the motors, the tractive effort capable of being developed by the machine corresponds to a coefficient of adhension well over 30 per cent., having been, in many cases, as high as 44 per cent.

It is by no means true that all locomotives at present available to the trade may be oveerloaded when the coefficient of adhesion is as high as 30 to 40 per cent. A locomotive can and should be over-motored. Then the proper weight of locomotivee is selected for the duty required, and regardless of the territory on which it is to operate, the machine will always have ample motor equipment.

Train resistance has absolutely nothing whatever to do with the draw-bar pull and motor equipment of a mine locomotive. If the train resistance is great, it simply means that a locomotive of given weight cannot haul a great load. The subject of train resistance is absolutely irrelevent material in the discussion of locomotive draw-bar pull and motor equipment.

Although it is possible to build certain sizes of railway motors with only two commutating poles, there are a great many sizes in which four such poles must be employed, and where this is the case, it is impossible to connect a reversible motor with fewer leads than shown in the diagram in my original article.

Any figures which may be submitted on the life of brushes and commutators are almost meaningless. To make such data of value, the mechanical construction of the motor, the grade of brush used, and the conditions of service to which the locomotive is put must be very definitely known.

The length of life of brushes and commutators on noninterpole emotors, which have come under my observation, have been very satisfactory, and I doubt if either could be greatly prolonged by the application of interpoles.

*Electrical Engineer, Jeffrey Mfg. Co., Columbus, Ohio.

Who's Who in Coal Mining

Herbert C. Campbell

There is plenty of room in the coal-mining industry for young life and blood, and quite a few of the so called second generation are availing themselves of the opportunities presented. The fallacy that only age and long experience are to be trusted has been exploded, and the world is better for it. Many corporations, once great, have gone to seed, simply for lack of the hope and enthusiasm that youth imparts. Great successes in mining as in all industrial and commercial life are but "dreams come true," and it is the air castles of our young men that materialize into the realities of our actual everyday existence.

H. C. Campbell

Our hard-headed, philosophical friends are always telling us of how hopeless is the future of the young man afflicted with a rich daddy. The handicaps, they say, are insurmountable, and even if the son himself isn't a pin-head, his environments are so unreal, so artificial, that all possibility of individual achievement is completely destroyed.

In the case of Herbert Campbell who was born in Kansas City, a little more than 30 years ago, the outlook, measured by above standards, was unusually dark. There wasn't any fake about the quality of the spoon in his mouth when he first saw the light of day. The article was solid silver and quite heavy at that. However, the family decided to take a chance, and the work of rearing the young man commenced. It so happened that the late Chas. Campbell, Sr., father of the boy, had ideas of his own concerning many things, among which were some data pertaining to laws, rules, regulations, and safety precautions relative to raising a boy in the U. S. A. Several times when Herbert wandered beyond the danger sign of the fireboss, Campbell, Sr., sent out a rescue corps, and later when alone, himself applied the first-aid measures.

As a result of such solicitous care, Mr. Campbell, Jr., became cautious, absorbed an education at St. Paul's School in New York, and on receiving his diploma, hurried back to Kansas City, arriving there in time to report on the morning shift. That same day, long before noon, the following entry was made on the books of the Central Coal & Coke Co.: H. C. Campbell, clerk, auditor's office.

They say the reason he was placed in the auditor's office was to teach him that the best opinion of responsible people in America favors the plan of demanding and getting 100c. in value for every dollar expended. It's good training for a young man to see, think, and talk all day about sums of money representing many thousands of dollars, and then after work, have to walk 37 blocks to save 5 cents.

At any rate, the drilling in the auditor's office was so comprehensive, and Mr. Campbell's conduct was so exemplary, that the company decided to remove all his illusions concerning the color and characteristics of coal, and forthwith ordered him to their mines in the Arkansas field, tempering their verdict of "guilty" by listing him on the payroll as assistant superintendent of the Arkansas mines.

Right here let me say it would be a good thing if all coal-company auditors were sometimes lifted gently but firmly from their office chair and conveyed without delay to the place where the coal is mined. Arriving there, they should be inclosed in neatly tailored overalls and jumper, and a delicately carved utensil commonly spoken of as a shovel should be placed in their hands. Next we have a pile of coal just shot from the face, an empty car, a starter's pistol and a recording stop-watch. I'm sure the picture is complete.

And that isn't all. It is just as essential that mine superintendents be subjected to an occasional change in climate. They might with advantage recreate in the auditor's office, punch a time clock, wear a fancy vest, a stiff collar and swear off swearing. To make the super feel at home amid his new surroundings, someone might be specially designated to blow coal dust in his face, singe his hair and drop a light weight of some kind on his head, all at stated intervals. The benefits of such a change are obvious.

But returning to Mr. Campbell, his stay in Arkansas was ended when the "big boss" appointed him assistant superintendent of their Kansas mines. This job kept him busy for three years, when he was advanced to the more responsible place of assistant manager of all the company's coal properties. Five years have elapsed since this last advancement, and they say out West that Herbert is making good with both feet. True, he found it necessary to run over to Kentucky and carry off for his very own a blushing Southern bride. But this is the only time he ever weakened, and since the company's punishment was inflicted in the form of a raise in salary, no great damage was done.

Mr. Campbell is a director of the Campbell Glass & Paint Co., and a director of the East Oregon Lumber Co The Country Club, Blue Hills Golf Club and Commercial Club, all of Kansas City, list him as an active member. He is likewise interested in the work of the Rocky Mountain Coal Mining Institute, having played the part

of host on the institute's stop at Rock Springs in June, 1913.

There is no more popular young man in the coal industry of the Middle West than "Herb" and no one who is more democratic.

Extracts from a Superintendent's Diary

It falls to my lot to witness often the gullibility of the average human.

We mining men have a way of shrugging our shoulders and smiling whenever one of our friends in town mentions some newspaper or magazine article dealing with an event at a mining camp, because we have come to know that such articles are always either greatly exaggerated or are ridiculous. But of late I am beginning to realize that such things are not always chargeable to malice and ignorance on the part of editors, but rather to their reporters, who swallow highly colored facts that are volunteered to them by the average mining-town citizen.

It has always been the policy of men in charge of large mining operations to talk as little as possible and it naturally follows that whenever newspaper reporters want to work up a feature story, they waste little time on bosses, but rather fall back on the talkative ones, whatever their prejudices and position may be.

That's where the fun begins if the miner encountered is possessed of a sense of humor. He does not stop to think of the possible effect of a published story built up on the statement he is volunteering, but only anticipates the laugh he will have on the reporter and then later on his acquaintances in town.

I have accompanied numbers of people into coal mines on their first trip and I have yet to see one who was not in a mood to believe most anything that might be suggested, if accidentally left in darkness for even a moment.

I always recall in this connection a sentence from one of Stevenson's essays: "Certain dark gardens cry aloud for a murder; certain old houses demand to be haunted; certain coasts are set apart for shipwreck.

A young reporter arrives at a camp in search of a story; although he has never been near a mining camp before, he feels that miners must be a pretty brave lot to hazard death by explosions, fires and all of the other terrible things that happen around them. And being a pretty decent sort of a chap, he plainly shows his admiration for all of the smutty-faced miners who pass him on their way from the pit mouth. Later on, at the boarding house, he gets on friendly terms with some of the younger men and they exchange confidences. Gradually they begin to realize that they are heroes in this young fellow's eyes and, unconsciously, perhaps, by word of mouth, they begin to live up to expectations.

Many of the terrible tales (imaginative) of hardships imposed by employers can be traced back to such interviews, as can also tales of wanton sacrifice of men due to failure on the part of those in power to adopt well known safeguards.

During strikes, the encounters between the "thugs" (the romantic name for mine guards) and the miners, as told by the miners to the reporters, take precedence over the ordinary adventures inside, and here again the same influences can be detected if one reads between the lines.

I am reminded of all this by a conversation I overheard tonight between our boss driver and a young cousin of his who is here on a visit from a distant farming section. The driver remarked that today he cut into an old room in the mines (he has to my knowledge never cut anything larger than a piece of pine and never used anything for cutting heavier than a pocket-knife) and found himself facing a skeleton. They were probably the bones of a victim of an explosion that occurred years ago. "We miners must always keep our nerves keyed up to expecting something of that sort," was the way he ended the narrative.

A Dust Arrester for Drilling and Boring Machines

Much attention is being paid at present to the avoidance of free or floating dust during drilling or boring in stone, coal or other materials. One method of attacking this problem is by directing a spray of water onto the part where drilling is in progress, but this is not always possible, unless a supply of water is easily available.

An alternative arrangement which has been introduced by Holman Brothers, of Camborne, England, under the patents of M. T. Taylor, consists of providing the drilling or boring machine with a means of arresting and collecting the dust so that it cannot permeate the air.

The boring tool is provided with a cup or receptacle slipped over the shank and having a soft-edged mouth, which accommodates itself to the rock surface when pressed against it. The soft edging at the mouth of the receptacle is secured by a sponge collar or gasket.

At the lower part of the receiver a nozzle is arranged, from which the dust is led away through a hose into bags or a water trough. A gland closed at the lower end by a rubber washer fits around the drill.

The machine when it commences to bore compresses a spiral spring, which butts against the cup receiver and forces it against the rock surface and the dust on coming out of the hole, being unable to make its escape because of the soft edging, passes away through the dust-collecting duct into the receptacle provided.

The whole arrangement is extremely simple, and easily applied, its simplicity of application is a strong point in its favor, inasmuch as the average miner is prone to give but little attention to his physical condition if such attention involves any extra trouble in the operation of his equipment. It is to be hoped that with the introduction of dust-allaying devices, miners' phthisis, of which so much has been heard in recent years, will be done away with, or at least effectively curbed.

Extracting Benzine from Coal

A new electrical process for extracting benzine from coal has recently been invented by a Swedish engineer, Mr. Vidstrand, of Stockholm; the costs of manufacture are said to be considerably lower than those with the methods now employed, and the product is stated to be as good as any fuel for motor cars. The process has been patented in eighteen countries and the inventor is carrying on negotiations with a group of Norwegian financiers with the view of disposing of the patent rights for Norway.

Editorials

Picking the Winners of First-Aid Contests

It will serve no good end for us to disguise the fact that there is a degree of uncertainty as to the quality of decisions in first-aid contests. There is no question but that an element of chance does enter in, and that not infrequently a team which does not deserve the fewest demerits carries off the palm in competition with teams whose execution is more perfect. And in this we have reference to no specific contest, nor to any particular series.

It is no great misfortune if a team entitled, we will say, to fifth place receives only seventh prize, nor if one entitled to a prize of low order is deprived of all award. But among the first three or four teams where competition is keen, the uncertainty in the result, due to faulty judging, is a matter of considerable discouragement, and eventually it will serve to reduce the interest in contests and limit the distance which contestants are willing to travel to attend meets. For crack teams will go a long way if only the award is sure to fall to the team of greatest merit.

We do not believe the interest will flag if one or two teams are invariably winners, so long as the contests are known to be fair. The international yacht races have lost little of their charm, though for years the American yacht has carried off the cup. But if a doubt were to arise in that nautical event as to the relation subsisting between success on the one hand and excellence of design and seamanship on the other, then the race would be deemed a useless event, and the sporting world would hardly maintain its interest from year to year.

Consequently, we think any method of performance and judging which will give the best team first place will serve a useful purpose and make the prizes obtained a cause of real gratification to the teams securing them.

We would suggest, therefore, that the events in which the contestants all enter, be regarded as elimination trials. Every capable judge should serve who can possibly be secured. There should, if possible, be as many judges as teams, and the men acting in that capacity should be, as far as may be, not only physicians, but men also having first-aid contest experience.

They should discuss the events beforehand and should agree on the preferable technique, and moreover they should decide what demerits they will give for any deviation from the desired procedure. Of course, the judges should be rotated and should not be connected, even remotely with any of the contesting teams. They should watch the manner of operation, as well as observe the final result. Moreover, a list of rules, far more complete than those we now have, should give the competitors a knowledge of what is expected.

But when all this preliminary judging is done, the first three or four teams should be selected for a final contest. So many of the judges we are obliged to employ are not mine physicians, for most of those who are interested enough to attend have teams entered. The local doctors in general practice have not studied first-aid as a science, and moreover do not know how to spot errors in technique as readily as do those who have trained teams for months or even years. Consequently, assuming a doctor can and does observe every move, the judgment of one of the judges may easily be slightly in error, and moreover, the lenience of one judge often wins a close contest.

In order that the winner may be the best team, we propose a final contest for the leading contestants. One team should be chosen to perform a certain event in the presence of all the judges. This event should not be preannounced. The other final contestants should be removed from the field, and when the first team has finished the final, the others, one by one, should come forward to perform the same event in the presence of the same judges. The award of the whole bench would be regarded with favor and confidence, and the fact that several teams had been already eliminated would probably make it possible to have the judging bench consist wholly of the medical directors of teams already out of the contest.

It may be objected that this will take time. It will, but where rescue work forms a part of the meet, the final first-aid contest could take place concurrently with the rescue events.

We believe that such a system will lead to great advances in execution and to discussions of technique more valuable than have yet arisen. The hurry on the field before the main contest makes it hard to get the careful consideration necessary to determine just how some six separate events should be conducted. So far the American Mine Safety Association has done only a small part of the work needed in formulating rules for action in the field, and there is a large degree of uncertainty as to whether demerits will be awarded for certain methods presented. If the rules of the game are undecided, and the ideas of each judge are the final laws for the teams he inspects, then there can be no confidence, and without confidence there can be no real contest.

Our Commercial Relations with Brazil

Ever since James G. Blaine, while secretary of state, attempted to establish a better political understanding with the various other nations of the new world, there has been a persistent feeling among Americans that this country should have a closer commercial relationship with our sister republics to the south. The present conflagration in Europe has afforded our first real chance to cultivate and foster such a relationship. Fate, unbid and unsought, has laid opportunity at our door.

Of the two great South American republics by far the larger in land area is Brazil, and unlike all other countries in America, the language there spoken is Portuguese. In spite of the discoveries and contributions to our geographical knowledge made by our well known and intrepid ex-president along the "River of Doubt," Brazil is

nevertheless about the only country in the world today across the map of any considerable portion of which may be written the word "unexplored."

Notwithstanding the fact that perhaps the major portion of the area of the country is virgin forest or wild land, Brazil has a population of about 22,000,000 people. It has also approximately 15,250 miles of railway and many thousand miles of navigable rivers.

The gradual increase in the exportation of the products of the country which has taken place for some considerable time past was not continued during last year, the total value of exports decreasing from $362,245,951 in 1912 to $313,628,078 in 1913. This decrease is accounted for by the lower market prices paid for coffee and rubber, the two products which for many years have constituted over 80 per cent. of the country's export.

The United States is the largest purchaser of Brazilian products, absorbing more than Great Britain and Germany put together. Besides purchasing 36 per cent. of the exports of coffee, this country buys the bulk of the Brazil nuts, cacao, carnauba wax, manganese ore and skins exported. On the other hand, we sell to Brazil only about one-third as much as we buy.

So far as we are able to learn, of coal or other solid mineral fuel, Brazil produces none or practically none. Throughout the rural districts, particularly in the states of Pernambuco and Sao Paulo, where sugar is a staple product, the mills almost exclusively burn wood and bagasse under the boilers. The same is true also of the domestic fuel consumed. Wood is, however, rather expensive and is becoming more so from year to year.

During the year 1913, Brazil purchased coal to the value of $19,505,066 and patent fuel or briquettes to the amount of $2,668,068. Of these amounts the United States furnished coal to the value of $2,162,098, while Great Britain furnished almost the entire balance.

Approximately 75 per cent. of the imports into Brazil come from the United States, Great Britain, Germany, France and Argentina. The percentages of these countries being 15.7, 24.5, 17.5, 9.8 and 7.4, respectively. These importations consist mainly of arms and ammunition, breadstuffs, cotton and cotton manufactures, coal, clocks and watches, chemicals and drugs, vehicles and accessories, electrical machinery and supplies, fish, fruit, glass, scientific instruments, iron and steel manufactures, leather and leather goods, meats and dairy products, musical instruments and accessories, naval stores, oils, paper and manufactures thereof, vegetables, wood and wooden goods, and miscellaneous articles of various kinds.

During 1913, Brazil exported products to the five countries previously mentioned, valued as follows: to the United States, $102,436,302; to Germany, $44,333,640; to Great Britain, $41,650,331; to France, $38,637,801 and to Argentina, $14,830,127.

The principal articles exported consisted of Brazil nuts, bran, coffee, cacao, cotton, cotton seed, carnauba wax, gold, hides, manganese ore, monazite sand, precious stones, rubber, skins, sugar and tobacco. Of these, the United States took the major portion of the Brazil nuts, coffee, cacao, manganese ore, rubber and gems.

In the number and tonnage of vessels, both steamships and sailboats entering Brazilian ports in 1913, the nations other than Brazil in order of their rank were Great Britain, Germany, France, Italy, Austria and Holland. Ten steamships and three sailing vessels, having a gross tonnage of 37,057 and 2448, respectively, are listed as being North American. It is doubtful if even one of them flew the Stars and Stripes.

Extensive improvements on the docks at Rio de Janeiro, where all vessels entering the port now come alongside, have been completed, together with modern warehouses and coal- and ore-handling apparatus.

Brazil is naturally one of the richest countries in the world, but her wealth lies almost wholly in her soil and climate. She has a diversity of products such as this country could well use. Something like 300 different kinds of useful woods including such varieties as ebony, mahogany, Spanish cedar, iron wood, ivory wood and bamboo, might be to advantage exported to this country for furniture manufacture. Her supplies of fuel are, however, deficient, and it is believed that henceforth coal, coke and briquettes will form an ever increasing portion of Brazilian imports from the United States.

A Big Slump in the British Exports

The figures for the British exports for the first month of the European war show the expected heavy decline. The gross exports of all kinds, including fuel, fell off 45 per cent. in value, as compared with the same month last year. It should also be remembered in this connection that these figures do not show the full force of the curtailment for the entire 30-day period. The declaration of war only occurred on Aug. 4, and it was a number of days after this before the complete cessation in shipping became effective. It is only fair to state in this connection, however, that much of this enormous falling off is due to unwarranted apprehensions among those in the affected industries and also to the disruption of the customary channels of business; it is, therefore, fair to assume that much of this is of a temporary character.

The fuel exports experienced a particularly heavy decline, the gross for the month aggregating only about three million tons, or about one-half normal. The most interesting and significant phase of the British export figures to the American operators, is the enormous decrease in the South American shipments. The August exports to the Argentine Republic amounted to only 98,344 tons, as compared with 290,741 tons for the same month last year, and 312,387 tons in 1912. In this one instance, therefore, we have a flat loss of nearly 200,000 tons, which cannot now be made up with anything except American coal.

While this is perhaps the most important tonnage that American operators can expect to obtain, there are other possible contracts involving relatively large volumes of coal. For instance, the British exports to Uruguay decreased from 72,006 tons in August, 1913, to 39,103 tons in this year, the relative figures for Brazil for the same period being 111,504 and 48,983, respectively.

The greatest decline in British exports, very naturally, was to Germany, the figures for August, 1913, being 798,177 tons, as compared with 132,026 tons for August of this year. It is interesting to note, however, that the shipments to Russia have suffered almost equally as much, decreasing from 769,794 tons in 1913, to 169,353 tons this year.

Forfeiture of Coal-Mining Leases

By A. L. H. Street*

SYNOPSIS—Although an agreement authorizing forfeiture for breach of a material condition will be enforced by the courts, the decisions are not uniform as to whether breach of the lessee's implied obligation to diligently carry on operations will sustain an involuntary cancellation of his rights. Right to forfeiture may be lost through the lessor's acquiescence.

One of the legal phases which frequently arises in coal-mining litigation is that pertaining to the right of a landowner to forfeit a coal-mining lease granted by him, for default on the part of the lessee—usually failure to commence or continue mining operations. In showing the policy of the courts on this question, I leave out of consideration cases which involve abandonment of a lessee's rights, confining myself to instances in which there is no showing that he ever intended to relinquish his rights—an essential element of abandonment.

Although all the courts probably agree that, even when there is no express covenant on the lessee's part to commence operations within any particular time, he is impliedly bound to work the property with a reasonable degree of diligence. And judicial authority is unanimous to the effect that a right of forfeiture for breach of a material covenant on the lessee's part, *expressly* reserved, will be enforced. The judges disagree, however, on the proposition as to whether breach of such an *implied* obligation will afford the lessor the right of cancellation. The Circuit Court of Appeals and the appellate courts of North Carolina and Virginia have sustained this right, while it has been held in other jurisdictions, including Ohio and Pennsylvania, that, in the absence of express reservation of the right of forfeiture, it does not exist. Under the latter view, the lessor's only remedy is an action for damages.

Leading Decisions Cited

In the case of Smith vs. Eagle Coal & Mercantile Co., 155 Southwestern Reporter 886, the Missouri Court of Appeals recognized the right of a lessor to enforce an expressly reserved right of forfeiture for failure of the lessee to pay royalties, or for suspension of operations for more than sixty consecutive days not attributable to strikes, car shortage or legal proceedings. But in this case a forfeiture was refused because it appeared that a suspension of operations relied upon by the lessor was due to a strike.

In the case of St. Louis Union Trust Co. vs. Galloway Coal Co., 193 Federal Reporter 107, the United States Circuit Court for the Northern District of Alabama announced the following principles:

Shortage in the payment of royalties is no ground for forfeiture, if innocent and if the lessee offers to pay the full amount due. Making of a mine-working contract by the lessee with a third person does not constitute a violation of a stipulation against assignment of the lease without the lessor's consent, so as to entitle the latter to enforce a forfeiture on that ground. Nor did use of narrow work in the removal of coal from adjoining land forfeit the lessee's rights. No forfeiture will be declared for claimed failure to properly develop the property, if it appears that the lessee has proceeded in good faith, and if the proper manner of development was largely a matter of judgment.

Forfeiture for Unreasonable Delay

But, where a lessee agreed to commence operations within one year from the date of the lease and continue developments to ascertain whether the property could be profitably worked, the lessor was entitled to forfeiture on showing that for 24 years the lessee had failed to proceed. (Kentucky Court of Appeals, Diamond Mining & Developing Co. vs. Sellars, 136 Southwestern Reporter 1016.) In a similar case (Brown vs. Wilmore Coal Co., 153 Federal Reporter 143), a lease was canceled as being a cloud on the lessor's title, where the lessee had failed to proceed with operations for 20 years, although mining was extensively carried on in the vicinity in the meantime. But the Kentucky Court of Appeals refused to decree a forfeiture because a lessee failed to commence operations within ten days and failed to do the development work required by the contract. (Ross vs. Sheldon, 119 Southwestern Reporter 225.) This decision was influenced, however, by the facts that time for commencement of the work was not made of the essence of the contract, no right of forfeiture was expressly reserved, and the lessee acted in good faith, having been delayed in his operations by illness and a temporary difficulty in obtaining necessary funds. It was further decided in this case that a lessee is not chargeable with delays arising after lessor brought suit to terminate the lease.

In Price vs. Black, 101 Northwestern Reporter 1056, the Iowa Supreme Court refused a forfeiture where it appeared that the lessor had acquiesced in a delay in prosecuting the mining and a large expense had been incurred in constructing a shaft to carry on the work just before suit to declare a forfeiture was brought.

On the other hand, the West Virginia Supreme Court has decreed cancellation of a lease for failure of the lessee to conduct operations for a period of two years and three months, where the lease contemplated production on a monthly royalty basis at the end of one year. (Starr vs. Huffman, 59 Southeastern Reporter 179.) And the Missouri Supreme Court forfeited a lease for sixteen months' delay. (Brooks vs. Gaffin, 90 Southwestern Reporter 808.)

Lessee Cannot Dispute Lessor's Title—A person who occupied coal lands under a lease and option could not dispute the title of the lessor, nor could a coal company which claimed under an assignment of the lease and option. (Oregon Supreme Court, Rouse vs. Riverton Coal & Development Co., 142 Pacific Reporter 343.)

Discussion By Readers

Method of Working Underlying Coal Seam

Letter No. 1—Referring to the proposition of Mr. Lyman, as described in his inquiry, COAL AGE, Aug. 29, p. 357, I had hoped to see this proposition fully discussed by the practical readers of COAL AGE, and will venture to express my own opinion in reference to the working of this seam of coal, in the hope of inducing others to do the same. Perhaps no subject is of greater interest to mining men than that relating to the economical and safe mining of coal under difficult conditions.

In the first place, in my opinion, neither the thickness of the seam nor the nature of the strata lying immediately above and below this coal present any features that would recommend the adoption of the pillar-and-stall system of mining. In all pillar systems applied to the mining of coal, one of the greatest difficulties experienced is the question of keeping the roadways open, as the development of the mine progresses. In all pillar systems of mining, the danger of squeeze exists to a greater or less extent, and the extraction of the coal is accompanied or followed by a greater or less settlement of the roof, which is sometimes gradual and gives little trouble, but more often results in breaks and roof falls that hinder and endanger the work and increase the cost of getting out the coal.

Owing to these considerations, in the adoption of the pillar system of mining, it is necessary to take the precaution of driving all roads with a sufficient height or headroom that will provide a good margin of safety. Unless a sufficient allowance be made for head clearance above the top of the loaded car, taking into account the settlement of the roof that is certain to occur, it will frequently be necessary to suspend work at the face temporarily, while lifting bottom or brushing the roof.

In the present inquiry the thickness of the seam is given as 4½ ft.; and it is stated that the roof is composed of soft shale, slate and limestone. These conditions make it almost certain that stringers or crossbars will be required to support the roof. These crossbars or collars will occupy from 6 to 12 in. at the roof, while the track will require 6 in. more at the floor, leaving only about 3 ft. of clear headroom above the rail. The soft floor is also an item that must be considered before adopting any pillar system of mining, as the weight coming on the pillars will have a tendency to heave the bottom.

Taking these considerations into account, I would recommend the adoption of the longwall-retreating system of mining. It is true that, in the adoption of this system, the roads must first be driven to the limit; but, since these are made in the solid coal, they will be more permanent and require the handling of less waste material than would be necessary in any pillar system. The work, generally, will be much safer, the extraction of the coal more complete, and the ventilation of the mine will present fewer difficulties than when mining on the pillar system. The longwall system also insures a larger output of coal for the same length of roadway, which reduces the cost of maintaining the roads; also, the work of collecting the cars, at the face, is much simplified, because the work is more concentrated. There is generally a greater percentage of lump coal produced in longwall mining; and the roof settlement being more gradual, less damage results on the surface. By the adoption of the retreating longwall plan of mining, there will be less danger of the pillars in the overlying seam breaking through into the workings below, provided suitable attention is given to the stowing of the waste behind the longwall face, as the work proceeds.

No doubt some would prefer the adoption of the pillar system of mining in this case, notwithstanding the existing conditions, had the thickness of the coal been greater, which would then require the handling of less waste material in the rooms. I hope to see this proposition further discussed by men whose experience will be of value to us all.

JAMES DICKSON.

Nanaimo, B. C., Canada.

The Safety Lamp and the Eyesight

Some time since, I remember, the question of the effect of the safety lamp on the eyesight was discussed in COAL AGE. Since that time, my eyes have become affected by the use of the safety lamp; and I would like to ask if anyone can tell how long it would probably be before a person so affected would become totally blind and what could be done to prevent such a calamity.

The trouble with my eyes began with an apparent swinging motion of the floor or the ground on which I stood. I next noticed that lights, at about 500 ft. distant, began to revolve when I looked at them. This has grown worse recently, and, now, lights close at hand often seem to revolve as I look at them. This continues until I can't see at all. I can see the light on my safety lamp, however, as well as ever; but when I proceed to put the date of my examination on the coal face, my hands seem to swing around and around. I have been firebossing for seven years continuously. I would very much appreciate some of our readers giving me further information, so that I will know when I ought to quit.

J. MILES KEMP.

Maben, Ala.

[In the discussion of the question of whether the continuous use of the safety lamp, in coal mining, affected the eyesight of miners, COAL AGE, Vol. 4, a great number of varying opinions were expressed; but, as stated in review of this discussion, COAL AGE, Vol. 4, p. 585; and Vol. 5, p. 135, it has not been shown that healthy eyesight has been impaired from this cause. Men who had used the safety lamp continuously for more than a quarter of a century, testified to having as perfect eyesight as could be expected if they had not used the lamp.—ED.]

The Reverse or Counter-Current Theory

Letter No. 8—In his recent letter, COAL AGE, Sept. 5, p. 398, Mr. Ashworth seems to infer that there is a collaboration between Mr. Verner and myself with respect to the graphic illustration of Mr. Verner's theory of the initiation and cumulative effects of a coal-dust explosion, which appeared in my letter, COAL AGE, Vol. 5, p. 1059 and was reproduced in the issue of Sept. 5, p. 398. In justice to Mr. Verner, I feel it my duty to state that, so far as I am aware, this diagram never received his sanction.

Believing, with Mr. Ashworth, that an idea or theory can be more clearly and comprehensively conveyed by a diagram when the subject matter will permit, I embodied my idea of this theory in a graphic illustration, trusting that, if my conception was wrong, Mr. Verner or some other authority would point out the error, that myself and others might profit thereby.

In his criticism, Mr. Ashworth remarks:

> It is clear, however, that no such reverse current would be produced until the force exerted by the powder or other explosive had expended its energy.

This statement, though slightly indefinite, agrees practically with what I stated, in my explanation, p. 1059, to the effect that a reverse current will *not* take place until the force of the blast "becomes more or less exhausted" or is opposed by an equal or stronger force, through the elasticity of the air compressed. Also, that the reaction between the resulting compression and depression would manifest itself at the point of least resistance, at the floor. If I have correctly interpreted Mr. Ashworth's meaning there is no difference of opinion in this respect.

Again, Mr. Ashworth remarks:

> It would seem also that, at the point C in the figure, the air would be in a state of compression instead of a depression or vacuous condition, existing.

I have always regarded the gas and flame of a blown-out shot as analogous to a projectile. If a projectile strikes a nonelastic body, the greatest compression will occur at the point of impact; and, if complete penetration takes place, alternate compression and expansion will result in different parts of the mass. If, however, the body struck be elastic, the compression of the area of impact will result in an expansion of the surface or mass not in the line of impact. Air being elastic may therefore be expected to expand toward the line of impact, thereby creating the vacuous condition at *C* and along the line of discharge. Mr. Ashworth's method of proving my deduction to be incorrect is not consistent with his own statement, as his diagram, Fig. 2, accepting for the purpose his argument, proves the existence of a vacuous condition along the longwall face, on each side of the shot, in which respect it does not differ from the diagram I submitted.

Mr. Ashworth further observes that, in explosions of this kind with which he has had experience, he has "observed that there was invariably a large cavity or air space in the immediate neighborhood of the blast." I take his meaning to be that such an area is more favorable to a general expansion of the blast, and furnishes besides, a sufficient supply of oxygen for the initiation of the explosion. So far the logic is sound; but, if he intends to say that an explosion will not occur except through the agency of such an area, I fail to grasp the argument. That explosions have occurred where such a condition existed, is no proof that an explosion will not occur where such condition does not exist, if the necessary factors for its occurrence be present; and the reverse current supplies these factors.

Mr. Ashworth's opinion that "when a shot blows out, the heated gases and particles of solid matter are projected into the mine roadway where the blast stirs up the dust" is generally conceded to be correct. But speaking of the initial moment when the fatal blast occurs, he says:

> At this initial moment, the atmosphere in the immediate vicinity of the shot is quickly rendered devoid of oxygen, which makes an explosion of the dust and gas at this point impossible.

I regard this statement as a very strong argument in favor of Mr. Verner's theory; but a practical test, as has been suggested, would be to place a barrier across the air course so as to prevent the supplying of sufficient oxygen for the necessary combustion through the agency of the reverse current.

Mr. Ashworth, in concluding his remarks, says there has not been shown "any reverse current other than that due to the cooling of the heated gases, which occurs in what is properly called, the condensation stage, etc." If this be true, then such an explosion would be characterized by only one compression and one expansion. In a recent issue of COAL AGE (Aug. 22, p. 294), there was given a description of an experimental explosion at the British experimental station at Eskmeals. At the mouth of the experimental tube a marker indicated upon a plate the compressions and expansions of the atmosphere, from the moment of the occurrence of the blast to the termination of the explosion, plainly showing that more than one compression and expansion took place.

Mr. Ashworth has not touched upon the cumulative effects of a coal-dust explosion which I believe is one of the principal things the theory seeks to explain. I question whether a practical test of Mr. Verner's theory, by the methods he has suggested, would result in the prevention of an explosion; but that the cumulative effects of such an explosion may be due to such a cause, I see no reason to doubt.

I. C. PARFITT.

Jerome, Penn.

Letter No. 9—I notice, by Mr. Ashworth's letter, COAL AGE, Sept. 5, p. 398, that he rejects the theory that the counter-current set up in a mine entry, immediately following an explosion of gas or dust, becomes a factor in the development and propagation of the explosion throughout the mine.

I want to express my indebtedness to Mr. Parfitt for his detailed explanation, COAL AGE, Vol. 5, p. 1059, of the action of such counter-currents occurring as an incident of the initial explosion at the face of a room or entry. I feel assured that Mr. Ashworth, after he has read Mr. Dean's description of the test at Eskmeals Experimental Station, COAL AGE, Aug. 22, p. 294, will no longer doubt the existence of the counter-current, in dust explosions, and its influence in the initiation and propagation of the resulting mine explosion.

At the present time, I will only briefly review Mr.

Ashworth's criticism of Mr. Parfitt's illustration, which is reproduced as Fig. 1, p. 398. The diagram represents an ideal or suggestion of what may reasonably be assumed to take place when a shot, fired at the face of a chamber or heading, is discharged into an explosive atmosphere of gas or dust. The principal force of the explosion is shown as projected along the roof of the heading, giving rise to a counter-current setting in along the floor at a point marked *F*. Referring to this sketch, Mr. Ashworth states:

> It is clear, however, that no such reverse current could be produced until the force exerted by the powder or other explosive had expended its energy.

My own observations and the results at Eskmeals and elsewhere have proved, to my mind, that the reverse current is not delayed until all the energy of the explosive blast has been expended; but that such a current sets in immediately after the explosive force has reached and passed its maximum; or, in other words, as soon as the pressure begins to decline. I am pleased to say that I regard Mr. Parfitt's sketch, in this respect, as fairly representative of true conditions in the mine.

Mr. Ashworth, further, doubts the existence of "a depression or vacuous condition" behind the blast when the shot is fired at the face of a heading, as indicated by *C* in Mr. Parfitt's Fig. 1, and suggests that a shot fired at a gate-end, in a longwall face, might produce such a condition by drawing the air from the road along the face, after the principle of an injector (Fig. 2, p. 398). I consider that the large space open at the longwall face suggested by Mr. Ashworth would prevent any depression being formed there at the moment the shot is fired.

Permit me to say, in conclusion, that the existence, during every dust explosion, of air inrushes, counter-currents, reverse impulses, or any other name by which these air movements may be known, has been established, by the experiment at Eskmeals, in the most convincing manner. Granting this to be true, the next step, in my opinion, should be the investigation of the function of such a reverse current. In other words, an effort should now be made to show how such currents influence the initiation and propagation of a dust explosion throughout the mine. This is what I have termed the "air factor" in a mine explosion. It is possible, I believe, to carry this investigation to a final conclusion and establish beyond a doubt what this influence may be. When that work has been accomplished at experiment stations, we shall possess more definite information in regard to mine explosions and be able to determine more effective means for their mitigation or prevention.

JOHN VERNER,
Former State Mine Inspector.
Chariton, Iowa.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

Theory of Siphoning—In order to operate a mine siphon successfully it is absolutely necessary to understand the theory of its working, and to know its limitations, and be able to detect the causes of failure when the results obtained are not satisfactory. Aside from the requirements of an air-tight pipe line and the complete or effective submergence of the ends of the pipe and assuming a clean bore, unobstructed by corrosion, sharp bends, globe valves, etc., there are other important considerations that affect and limit the flow of water in a siphon.

1. It is necessary to consider the flow of water from the intake end to the summit (short leg), as independent of the flow from the summit to the discharge end (long leg). The flow in the short leg is caused by the pressure of the atmosphere; that in the long leg is due to gravity.

In the **short leg** the gravity head (h_1) opposes the atmospheric head (H), which gives,

Effective head (short leg), $H - h_1$

In the **long leg,** the atmospheric head **(H)** opposes the gravity head (h_2), which gives,

Effective head (long leg), $h_2 - H$

2. It is evident, at once, that the gravity head (h_1) or rise in the short leg must always be less than the atmospheric head (H), in order that water shall flow to the summit of the pipe, and, further, as the rise of the pipe approaches the atmospheric head, the effective suction head will be correspondingly less.

The **atmospheric head** varies with the elevation above sea level and is, besides, subject to barometric changes. The average atmospheric head at sea level, expressed in water column, is $14.7 \div 0.434 =$ say 34 ft., which is therefore the theoretical limit to the rise of a siphon, at sea level. Owing to the frictional resistance of the pipe and other obstructions to the flow, the practical limit of rise is much less.

A **practical rule** for calculating approximately the allowable rise or **suction head,** in siphoning or pumping is:

Rule—Approximately, under ordinary conditions, the allowable suction of a pump or siphon in feet, may be taken as nine-tenths of the height of the barometer, in inches.

3. The **flow in the suction end,** under the effective head $H\text{-}h_1$, is calculated by equating this effective head with the sum of the friction head and the velocity head expressed in gallons per minute (G); length of suction end in feet (l_1); and diameter of pipe in inches (d_1), which are as follows:

Friction head, $\dfrac{l_1 G^2}{800\, d_1^5}$

Velocity head, $0.0026\, \dfrac{G^2}{d_1^4}$

$$H - h_1 = \frac{l_1 G^2}{800\, d_1^5} + 0.0026\, \frac{G^2}{d_1^4}$$

Then, solving for G, the flow in the suction end is

$$G = d_1^2 \sqrt{\frac{800\, d_1\, (H - h_1)}{l_1 + 2.08\, d_1}}$$

The Coal Age Pocket Book

4. The **flow in the discharge end,** under the effective head $h_2\text{-}H$, is calculated in the same manner as before, by equating this effective head with the sum of the friction and velocity heads and solving for G, which gives

$$G = d_2^2 \sqrt{\frac{800\, d_2\, (h_2 - H)}{l_2 + 2.08\, d_2}}$$

5. The proper **design** of a mine siphon requires that the diameters of the suction and discharge pipes shall be proportioned to their respective lengths and effective heads.

To determine this relation, in practice, whenever the diameter of the pipe in inches, does not exceed its length in hundreds of feet, the velocity head can be ignored with an error that will not exceed one per cent. This eliminates the term 2.08d in the above formulas expressing the flow.

In order that the siphon shall run full continuously, without necessitating the throttling of the discharge, the flow of water to the summit, under the effective suction head must at least equal the flow from the summit, under the effective discharge head. Therefore, equating the expressions for these respective flows, and disregarding the velocity head,

$$\left(\frac{d_2}{d_1}\right)^5 = \frac{H - h_1}{h_2 - H} \times \frac{l_2}{l_1}$$

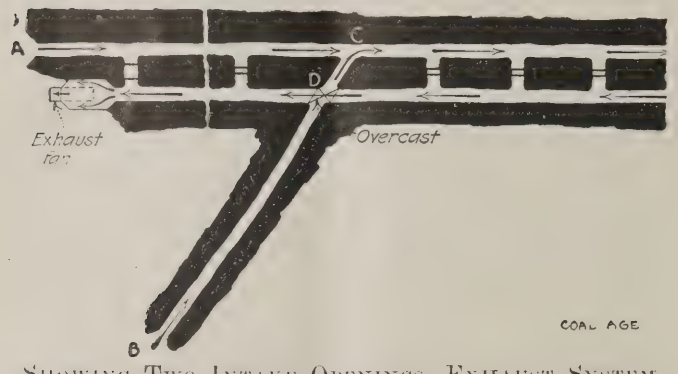
Or, the relation of the **effective head, diameter** and **length** of pipe, in the respective suction and discharge arms of a siphon, when the diameter of the pipe in inches does not exceed its length in hundreds of feet, is expressed by the following:

Rule—The fifth power of the diameter of the pipe varies directly as its length and inversely as the effective head. Or, in other words, the fifth power of the diameter ratio is equal to the length ratio multiplied by the inverse ratio of the effective heads.

When the dimensions of the pipe, in each arm of the siphon, respectively, are thus proportioned to the effective heads, which are producing the flow, the pipe will run full throughout its length; and the velocity of the flowing water will be such that there will not be the same tendency for the air contained in the water, to escape and accumulate at the summit of the siphon or pipe line.

6. The use of **air traps** and **valves** to throttle the flow of the water in the discharge, and thus prevent the siphon emptying itself or "running dry" are unnecessary devices in a properly designed pipe line.

An air trap is a chamber attached to the summit of the pipe line, its connection therewith being controlled by a stop cock or small valve that will permit water from the chamber to replace the air that accumulates at that point when the siphon is not properly designed.



When a valve is required at the discharge end of a siphon a gate valve should be used in place of a globe valve, as the form of construction of the latter presents greater obstruction to the flow of the water. A valve may be required to control the flow in a **poorly** designed siphon; **or** whenever the fall in the discharge end of the pipe exceeds the atmospheric head, expressed as water column.

Inquiries of General Interest

Taking a Water-Gage Reading In a Mine

In order to settle an argument in reference to the proper method of taking the water-gage reading in the mine illustrated in the accompanying sketch, will you kindly state which of the methods advanced is the correct one to adopt in this case, that the reading of the gage shall represent correctly the pressure producing the circulation in the mine.

This is a drift mine and, as shown in the sketch, the fan is exhausting the air from a single main-return airway. There are two main-intake roads by which the air enters the mine at *A* and *B*. These air currents unite at *C* to form a single intake current, which traverses the main-intake road and, after passing through the workings, returns to the fan by the main-return airway. The return current is overcast at *D*, before it reaches the fan. The arrows show clearly the course of the air.

SHOWING TWO INTAKE OPENINGS, EXHAUST SYSTEM OF VENTILATION

It is claimed by one party that, in order to obtain a correct water-gage reading in this mine, the gage should be placed on a stopping inby of the point *C*, where the currents join. The other party claims that a correct water-gage reading for the entire mine can only be obtained by placing the gage in such a position that it will indicate the difference of pressure between the main-return airway at the fan and either of the intake roads, close to the entrance of the mine or outby from the point *C*, where the currents join; or, what is practically the same thing, to take the gage reading between the fan drift and the outside air. He urges in support of his claim that "when a fan is exhausting, the barometric pressure of the outside atmosphere forces the air into and through the mine against the partial vacuum created by the action of the fan; and the difference of these pressures is the pressure measured by the water gage in the position he has suggested. We would like to see this question answered in COAL AGE.

U. S. WILSON.

Briceville, Tenn.

In the ventilation of a mine, the air always moves from the point of highest pressure which is the mouth of the intake, to the point of lowest pressure at the mouth of the return airway. The course between these points does not include the passage through the fan. When the fan is blowing, its location is at the mouth of the intake airway and the point of *highest* pressure, in this case, is in the fan drift, close to the fan; while the lowest pressure is the barometric pressure at the mouth of the return airway. When the fan is exhausting, however, the point of *lowest* pressure is in the fan drift, while the highest pressure is the barometric pressure at the mouth of the intake airway. In either case, the water-gage reading taken on the fan drift will show the difference between the highest and the lowest pressure of the circulation, which will be the correct mine pressure.

The fact that, in this case, there are two intake openings and two intake currents that unite at *C* to form a single intake current, does not alter the situation. Since this fan is exhausting, the barometric pressure of the outside atmosphere, at *A* and *B*, is the highest pressure in the circulation; and the pressure in the fan drift close to the fan is the lowest pressure. The correct position of the water gage when ascertaining the mine pressure is, therefore, on the fan drift close to the fan, but at such a distance from it as to avoid the violent oscillation of the water in the gage that sometimes takes place, owing to the eddying of the current or an unsteady action of the fan.

Adding Air to Reduce Flame Cap

Referring to the answer to an examination question, COAL AGE, Sept. 12, p. 444, it seems to me that the air required (37,300 cu.ft.) is not nearly sufficient to dilute the gas so that no cap will appear on the lamp. The amount of gas in the air current is found to be 946 cu.ft. per min.; but I do not understand why this is divided by 0.02 to obtain the total volume of the return current. Kindly explain.

INQUIRER.

South Brownsville, Penn.

If the 946 cu.ft. of gas is 2 per cent. of the total return current (air and gas) after dilution, 1 per cent. is

$$946 \div 2 = 473 \text{ cu.ft.;}$$

and 100 per cent. of the total return current including the air added, is then

$$473 \times 100 = 47{,}300 \text{ cu.ft. per min.}$$

The same result is obtained by dividing at once by 0.02, as in the answer given Sept. 12, p. 444; thus,

$$946 \div 0.02 = 47{,}300 \text{ cu.ft. per min.}$$

The original current of air and gas being 10,000 cu.ft. per min., the air added to this current is

$$47{,}300 - 10{,}000 = 37{,}300 \text{ cu.ft. per min.}$$

To prove this result, find 2 per cent. of the total return current, which is the gas present; thus,

$$47{,}300 \times 0.02 = 946 \text{ cu.ft. per min.}$$

Examination Questions

Wyoming Questions (1912)

(*Answered by Request*)

Ques.—What is afterdamp and why is it dangerous to life?

Ans.—Afterdamp is a variable mixture of the gaseous products of an explosion of gas or dust, generally mixed with more or less air. The composition of afterdamp is very variable, depending on the character of the gases burned and the conditions attending the explosion, in respect to the quantity of air available for the combustion of the gases. As the proportion of air (oxygen) available for combustion is increased, the percentage of carbon dioxide (CO_2) formed is increased, while the percentage of carbon monoxide (CO) formed by the explosion is decreased, as shown by the following:

Gas to air, 1 : 4.5; 10 per cent. of carbon burns to CO_2
90 per cent. of carbon burns to CO

Gas to air, 1 : 5; 13 per cent. of carbon burns to CO_2
87 per cent. of carbon burns to CO

Gas to air, 1 : 6; 20 per cent. of carbon burns to CO_2
80 per cent. of carbon burns to CO

Gas to air, 1 : 9.57; all of the carbon is converted into CO_2

Afterdamp is dangerous to life for two reasons; namely, the available oxygen is insufficient for the support of life; the gases composing the mixture are either poisonous or suffocating when breathed into the lungs.

Ques.—Explain the meaning of the terms, *ventilating pressure, water gage* and *resistance of air,* as used in mine ventilation.

Ans.—The ventilating pressure is the pressure producing ventilation. This should be the entire pressure exerted on the sectional area of the airway, which is the equivalent of the resistance to be overcome in passing the air through the airway. The term "ventilating pressure," however, is quite generally used for the *unit* pressure or pressure per square foot of sectional area.

The term, *water gage,* refers to the inches of water column supported by the air pressure producing the circulation. The water gage is, therefore, the measure of the difference of pressure between the intake and the return airways, in any given circulation of air. One inch of water gage corresponds to a pressure of 5.2 lb. per sq.ft.

The *resistance* of an airway is the force developed in opposition to the passage of air through the same and is equal to the pressure exerted on the total sectional area of the airway to produce the circulation. The resistance of an airway is expressed in pounds. It is caused by the friction of the air rubbing on the sides, top and bottom of the airway and the obstruction offered by timbers and other abutting surfaces that impede the flow of the air.

Ques.—(a) How is pressure measured in a mine airway? (b) Explain the constant, 5.2, used in connection with water-gage calculations.

Ans.—(a) The pressure producing circulation in a mine or airway is measured by means of the water gage, which is a U-shaped glass tube containing water in the bend of the tube. Both ends of the tube are open, one of these being connected with the intake while the other is open to the return airway. The pressure on the intake airway always being the greater, the water in this arm of the tube is depressed, while that in the other arm rises an equal amount. The difference between the two water levels of the gage is the water column that measures the difference of pressure between the two airways or the pressure producing the circulation. Since each inch of water gage corresponds to a pressure of 5.2 lb. per sq.ft., the water-gage reading multiplied by 5.2 will give the unit of ventilating pressure, in pounds per square foot.

(b) The weight of a cubic foot of water is practically 62.5 lb.; and the weight of water 1 in. deep spread over an area of 1 sq.ft. is, therefore, $62.5 \div 12 = 5.2$ lb. Since water always rises to the same level, this weight of water, in pounds, spread over 1 sq.ft. of area is equal to the pressure, in pounds per square foot, corresponding to 1 in. of water gage.

Ques.—If the length of an airway is increased four times, what is the effect on the friction of the air current?

Ans.—The friction will be increased in the same ratio as the length of the airway; or, in this case, the friction will be increased four times.

Ques.—If the velocity of the air current be increased four times, what will be the effect on the friction of the air passing through the airways?

Ans.—The friction increases as the square of the velocity of the air current. If the velocity be increased four times, the friction will be increased $4^2 = 16$ times the original friction.

Ques.—If an explosion should occur in the safety lamp when testing for gas, or the lamp should suddenly fill with flame, what would you do to insure your own safety?

Ans.—It is important, in either case, to make no quick movement, as that would increase the danger. An explosion within the lamp chimney indicates that the air entering the lamp approaches closely to the lower explosive limit. Owing to the presence of more or less burnt air within the lamp chimney, which reduces the explosive condition within the lamp, the air surrounding the lamp may at the same time be highly explosive. Under the observed conditions stated here, a quick movement of the lamp, by assisting the circulation, might cause a sharp explosion within the chimney that would pass the flame through the gauze and ignite the gas outside the lamp.

The flaming of the lamp indicates a similar condition within and surrounding the gauze chimney, but to a lesser degree. A quick motion of the lamp downward causes a greater upward pressure within the chimney and tends to transmit the flame through the upper portion of the gauze. In the flaming of the lamp, the moment of greatest danger is when the lamp is being removed from the gas into fresher air below. The entrance of the fresh air into the combustion chamber of the lamp increases momentarily the explosive condition of the gas-charged air within the chimney, which might cause an explosion that would transmit the flame through the gauze.

Coal and Coke News

Washington, D. C.

The Senate Committee on Public Lands has reported the bill to provide for leasing coal lands in Alaska, which passed the House of Representatives on Sept. 5, in an entirely new form. This provides for authorizing the Secretary of the Interior to survey the lands in the territory of Alaska, just as was done in the house bill. In Sect. 2 of the measure, 5120 acres of coal-bearing land in the Bering River field and 7680 in the Matanuska field are reserved to the United States for the purpose of mining for government use. Then the following draft of Sect. 3 is inserted with reference to the conditions under which the unreserved lands are to be taken up:

That the unreserved coal lands shall be divided by the Secretary of the Interior into leasing blocks or tracts of 40 acres each, or multiples thereof, and in such form as in the opinion of the Secretary will permit the most economical mining of the coal in such blocks, but in no case exceeding 2560 acres in any one leasing block or tract; and thereafter, subject to any prior valid existing rights, which said rights may be perfected under the laws in force at the time the same were initiated.

The Secretary shall offer such blocks or tracts and the coal, lignite and associated minerals therein for leasing, and shall award leases thereof through advertisement, competitive bidding, or such other methods as he may by general regulations adopt, to any person above the age of 21 years who is a citizen of the United States, or to any association of such persons, or to any corporation organized under the laws of the United States or of any state or territory thereof.

Provided, that no more than one of said blocks shall be included in any lease.

And provided further, that no railroad or common carrier shall be permitted to take or acquire through lease or permit under this act, any coal or coal lands in excess of such area or quantity as may be required and used solely for its own use, and such limitation of use shall be expressed in all leases or permits issued to railroads or common carriers hereunder.

And provided further, that any person ,association or corporation qualified to become a lessee under this act and owning any pending claim under the public-land laws to any coal lands in Alaska may, within one year from the passage of this act, enter into an arrangement with the Secretary of the Interior by which such claim shall be fully relinquished to the United States; and if in the judgment of the Secretary of the Interior the circumstances connected with such claim justify so doing, the moneys paid by the claimant or claimants to the United States on account of such claim may, by direction of the Secretary of the Interior, be returned and paid over to such person ,association or corporation as a consideration for such relinquishment, or in lieu of such repayment, the Secretary of the Interior may execute and deliver to said person, association or corporation, in preference to any other lessee, a lease under this act of the land so claimed or any part thereof within the limitations of area and location fixed by Sect. 2 hereof, and the said moneys may be credited upon the royalties to become due under such lease: Provided, that if the land so claimed be within a reservation made in pursuance of Sect. 7 of this act, other coal lands in Alaska of substantially equal value may be substituted in said lease for the lands so relinquished.

The later sections relate to details concerning the purchase or acquirement of mining rights by individuals. Sect. 9 reads as follows:

That for the privilege of mining and extracting and disposing of the coal in the lands covered by his lease ,the lessee shall pay to the United States such royalties as may be specified in the lease, which shall not be less than 2c. nor more than 5c. per ton, due and payable at the end of each month succeeding that of the shipment of the coal from the mine, and an annual rental, payable at the beginning of each year, on the lands covered by such lease, at the rate of 25c. per acre for the first year thereafter, 50c. per acre for the second, third, fourth and fifth years, and $1 per acre for each and every year thereafter during the continuance of the lease, except that such rental for any year shall be credited against the royalties as they accrue for that year. Leases may be for periods of not more than 50 years each, subject to renewal, on such terms and conditions as may be authorized by law at the time of such renewal.

Five Per Cent. Rate Case to Be Reopened

Contrary to expectations, the Interstate Commerce Commission has reopened the 5 per cent. rate case and will again hold hearings regarding it. There is no official assurance on the subject, but it is pretty generally understood that the commission has no intention of changing its attitude on the question of rates on heavy products, of which coal is a conspicuous example.

From all appearances, whatever the commission chooses to do will be done with due regard to the necessities of the coal industry, as already ascertained, and of others which are in a like position. There was no industry, it is learned, which made a stronger demonstration of its position during the hearing before the commission when the original 5 per cent. case was being heard than the coal industry.

HARRISBURG, PENN.

There is wide interest in the argument arranged for Sept. 25, on the "Mine foremen's certificate" case, which will be heard by Judge Kunkle, in this city.

The United Mine Workers are anxious to prevent the issuance of certificates to the successful candidates, who they allege have not had the requisite experience of five years in actual work of cutting coal at the face. The law requires that each applicant shall have had five years' experience as a miner, but the attorney-general recently applied an interpretation that "miner" means anyone engaged about the mines.

The United Mine Workers take a different view of the matter from that of the chief of the Department of Mines, who is abiding by the interpretation of the attorney-general. They began proceedings in the name of James Mathews, president of the Schuylkill district, to stop the issuance of certificates to the large number of men who passed the recent examination when the bars were let down. As a result, the certificates of the anthracite region have not been issued. The candidates who passed the examination have now retained ex-Judge A. L. Shay, who has applied for a mandamus on the chief of the Department of Mines, Hon. James E. Roderick, to compel the issuance of the certificates which were awarded by the examining boards.

Judge Shay claims that the court cannot go behind the returns of the examining board unless fraud is alleged, and that the board is sole judge of the qualifications of the candidates.

He quotes a decision of the Schuylkill County court in the case of Thomas Reese, who was refused a certificate for mine inspector. In that case, the court said it could not substitute its own discretion for that of the board and refused any relief to Reese.

The argument on Sept. 25, therefore, may not be on the merits of the question, but whether the courts have jurisdiction under the circumstances surrounding this case. The whole anthracite region is keenly interested in the matter. The miners have engaged as counsel, James J. Moran and ex-Congressman J. B. Reilly, who will argue that the safety of many thousands of men depends on having efficient and experienced foremen. Deputy Atttorney-General J. E. P. Cunningham will represent the Department of Mines.

A Medal Is Awarded

The Bliss breaker, owned and operated by the Delaware, Lackawanna & Western R.R. Co., was struck by lightning on July 27, 1914. The bolt tore off a portion of the roof and set the building afire, the employees running panic-strucken from the breaker to a place of safety. John Zabigolski, who is employed as a slate boss, instead of following his fellow-employees, picked up a hose and turned a stream of water on the fire, which resulted in saving the big building.

The company has just rewarded Mr. Zabigolski for his bravery by presenting him with a beautiful gold medal as an award of merit. The medal is engraved as follows:

SAFETY FIRST
AWARD OF MERIT
JOHN ZABIGOLSKI
JULY 27, 1914
MINING DEPT.

Mr. Zabigolski may well feel proud of the honor, since it is the first medal presented as a token of merit by the Lackawanna R.R. mining department in this region to any employee for an act of heroism.

PENNSYLVANIA

Anthracite

Girardville—Anthony Faran was killed and John Regan was seriously injured and four others were entombed for several hours when the timber in an old gangway collapsed under a fall of coal at Packer Colliery No. 5 of the Lehigh Valley Coal Co., on Sept. 17. A rescuing force reached the entombed men after three hours of perilous labor.

Ashley—Because it is alleged that three patchers employed in Maxwell Colliery, Lehigh & Wilkes-Barre Coal Co. had not been given an increase in pay which they claim was promised

them, and which they say is due them under the terms of the last agreement, a strike was called on Sept. 18, and the entire colliery was shut down.

Plymouth—A button strike was called at the Lance colliery, Lehigh & Wilkes-Barre Coal Co., at Plymouth. A number of men have refused to join the union and the others refuse to work with them.

The strike at the Dorrance colliery of the Lehigh Valley Coal Co., which grew out of the company's new regulation regarding car topping is still unsettled.

Wanamie—Officials of the Lehigh & Wilkes-Barre Coal Co. are considering the project of erecting a new breaker at No. 18 colliery. It is said that plans are to be made for a new all steel structure some distance from the present breaker. Electricity for power and modern machinery for coal preparation are to be used.

Mt. Carmel—Two men were killed and one fatally injured in the Midvalley colliery when a trip of cars upon which they were riding struck a mining locomotive. In order to avoid a long walk to reach home, 11 men and boys disregarded the rules and warnings of the company. The trip started at high speed when the cars reached a curve on the slope and crashed into a locomotive drawing a trip of loaded cars.

Hazleton—The anthracite mines in the Lehigh coal fields, on Sept. 14, started on their second week of steady time, which is to be continued indefinitely. The Lehigh Valley R.R. is getting ready for heavy fall coal business. Motive power is being repaired and cars are being gathered from all points to handle the traffic. With the mines in steady operation and local industries going nearly full blast the Hazleton region is not suffering depression. The European war has not yet caused any suspension of work at local mills; but as Hazleton and the surrounding towns depend mainly on the anthracite industry a good winter is ahead.

Bituminous

New Salem—The main business block of this place, an H. C. Frick Coke Co. town of about 2000 population, was destroyed by fire on Sept. 17. The damage is estimated at $40,000. A school building erected at a cost of $30,000 was burned several months ago. It is rumored that these fires were of incendiary origin.

Jerome—The probability of Sunday shifts to keep up with the great demand for its product was announced on Sept. 15, by the Jenner-Quemahoning Coal Co. Orders for coal from this company's mines are said to be piling up faster than the company can fill them at the present rate of mining, and long trains are being sent both east and west, loaded with coal. The condition is considered extraordinary by operators, as there is a noticeable slump in business in most of the workings in the vicinity.

Milford—The 700-acre tract that was optioned for the Hinchman Brothers of Mount Pleasant may be sold to Cambria County capitalists. The field under option includes coal underlying the farms of G. J. Hayes, J. M. Critchfield, A. J. Newman, Walker Brothers and F. F. Welmer. It has been learned that the Cambria County operators are favorably impressed with the quality of the coal and will likely purchase the tract together with several acres of surface upon which to build a plant.

Mines on all these farms have been opened and have been supplying local trade for several years. It is believed that the equipment for operating the tract will be placed on the Hayes farm, which is more accessible to the Somerset & Cambria branch of the Baltimore & Ohio and that the mine opening at this particular point has been better constructed. The deal for the 700 acres will likely be closed before the end of September.

Pittsburgh—The plans for the new buildings of the U. S. Bureau of Mines located in Pittsburgh have been completed and are now in Washington awaiting the approval of the government architect. It is expected that bids for the construction of these buildings will be invited and contracts awarded not later than Oct. 15.

Connellsville—The Connellsville coke region is now producing approximately 250,000 tons weekly, which is a new low record for the year. The coal market in the Pittsburgh district on the other hand, has been slightly more active as the result of increased demand for domestic purposes.

WEST VIRGINIA

Charleston—It is announced by the mine workers' organization that all contracts which expired in the Kanawha district in March have now been renewed and that the entire district is now at work without friction. Contracts are also being sought with the Milburn Coal Co. and the Solvay Coal Co., both of which have begun operations on Paint Creek. The miners working these operations have been working on a temporary agreement, but it is believed that there will be no difficulty in securing the consent of the two companies to operate under the general wage agreement.

Fatality records in the department of mines show that during the month of August, 32 men lost their lives in West Virginia coal operations. Chief Inspector Earl A. Henry is calling the attention of both miners and operators throughout the state to the number of accidents and deaths due to riding on loaded trips, 10 of the 32 fatalities during the month arising from this cause. Eleven more are classified as due to carelessness. A further classification shows that 15 deaths were due to falls of coal and slate, 10 to mine cars, motors and the like, 6 to electrocution, and one to machinery.

Welch—Complaint was recently brought before Justice of the Peace, A. T. Hufford, charging that William Concoski, of Superior No. 1 Mine, a Russian, was carrying matches and smoking under ground. The mine is worked on locked safety lamps and permissible electric lights. He was fined $100 and costs. This is the first case of its kind, and should be a lesson to others violating Sec. 18 of the Mining Law.

TENNESSEE

Chattanooga—Coal shipments are to begin soon from the developments the Castle Rock Coal & Coke Co. The capital of the company is provided and it is opening up the famous Coal City seam on the side of the mountain nearest Whiteside, Tenn., on the Nashville, Chattanooga & St. Louis R.R.

KENTUCKY

Whitesburg—Last week was a record breaker in point of coal shipments from the Consolidation Coal Co.'s plants in the Jenkins-McRoberts-Burdine fields, though definite figures are not available. The company is planning continued increases in its output.

Louisville—Of the 866,980 workers in Kentucky engaged in gainful occupations, 21,100 or 2.4 per cent. of the total are miners, according to the detailed report of the census bureau for 1910. Of the miners, all by but 9 were males, while of the total number of miners 18,310 were coal mine operatives.

Hazard—The Hazard Town Coal Co. is opening a large mine in the No. 4 seam of coal immediately west of Hazard, on the North Fork of the Kentucky River. The main line of the Lexington & Eastern division of the Louisville & Nashville R.R. is on the opposite side of the stream. The tipple will be built beside the railroad and the coal carried from the mine to it across the river in an aërial tramway.

Benham—The Wisconsin Steel Co. is now shipping a larger coal tonnage than at any time in the history of its operations in the Cumberland River field. At present the Wasioto & Black Mountain R.R., a branch of the L. & N. is taxed to the limit to handle the unusually large coal tonnage going out from the different plants. A large increase was made also last week in the working force of the company, while increases are billed to take place from time to time within the next two or three weeks.

OHIO

Columbus—The mine rescue car which was purchased several months ago by the Ohio department of mines has proven its worth. It has shown that the investment of $10,000 for the car has been a piece of wisdom and that it is one of the genuine assets of the department of mines. Upon two occasions the car and its equipment have been called upon and in both cases it has done all that was claimed for it. The first occasion was a fire in the mines of the Superior Collieries Co. at Wellston, where fire from the tipple was communicated to the interior workings. The car was called and with the aid of the equipment the fire was extinguished in three days. The second occasion was the opening of Mine No. 301 of the Sunday Creek Co. at Congo.

INDIANA

Indianapolis—The local inspector of weights and measures has ordered that coal in baskets must be sold by weight, 80 lb. of soft coal and 40 of coke to the bushel. A certificate of weight must accompany delivery.

ILLINOIS

Belleville—The annual report of the County Mine Inspector for St. Clair County gives a total tonnage of 5,117,002 tons of coal produced for the year. The 54 shipping mines in the County shipped 4,900,489 tons, and the local mines, numbering 17, shipped 107,514 tons. There are 160 mining machines, 27 locomotives and 4313 miners employed, with 425 men at miscellaneous labor. The shipping mines worked on an average of 145 days throughout the year, and the local mines worked 213 days.

Owners of 45 mines in the Belleville district have received letters from Adam Hoffman, Jr., of St. Louis, requesting that the present option for the purchase of these operations be extended for a period of 90 days. Hoffman who has been promoting a $15,000,000 deal had hoped to raise the capital in France. This plan has fallen through for obvious reasons.

Pana—The men of the Peabody Coal Co. recently went on strike because of the alleged refusal of the company to recognize the pit committee and the district president.

East St. Louis—It is rumored that the Prairie mine, owned by the Aid Coal Co. of St. Louis, is in such a condition that it will likely be abandoned on account of the excessive squeezes that have created doubt as to the likelihood of ever being able to operate the mine at a profit again. This is one of the largest and best mines in St. Clair County, but it has not been operated since early last spring.

Johnston City—The work of developing the property of the Cambria Coal Co., north of here, continues, and an enormous pile of coal, containing several thousand tons, has been taken out and heaped up waiting for the railroad extension to be built into the property. It is understood that the temporary top works will remain until next spring, when a steel tipple and up-to-date head gear will be erected.

Marion—Many of the mines in Williamson and Franklin Counties are able to run only about two or three days a week, on account of the congested condition of their storage tracks, and all sidings on the railroad, with steam coal. Some mines have over a hundred cars of the smaller sizes that they are unable to move at any price. At Johnston City one mine is dumping all of its screenings on a lot adjacent to the mine.

MISSOURI

Richmond—Perry Rice, of Richmond, has leased the Vibbard mine which has not been worked for several years; it is said to have a vein of about 27 in. at a depth of 400 ft. Mr. Rice is reported to be making plans to reopen the old shaft and sink another. The Santa Fe will build a spur to the mine.

UTAH

Eureka—A cave-in occurred recently in the 1600 ft. level of the Continental mine burying 12 mine workers. It is believed that all of these were crushed immediately.

FOREIGN NEWS

Cardiff, Wales—Miners producing the coal for the English navy have shown their loyalty in a manner highly gratifying to the Admiralty. In the face of attempts on the part of labor leaders to take advantage of the present situation for the enforcement of demands upon the Admiralty, the Welch miners have waived all holidays and are working Sundays whenever it is necessary to keep the navy supplied with coal. Union leaders asserted that it was not necessary for the men to surrender their holidays, but the latter disregarded their ruling.

PERSONALS

W. O. Stillwagon, of Mount Pleasant, Penn., is about to retire from the employ of the H. C. Frick Coke Co., after 33 years of service.

R. B. Waddell, formerly connected with the Commercial Coal Co., of Detroit, has accepted a position with the Colonial Coal & Supply Co., of Columbus, and will cover Northern Ohio.

S. A. Bramlette has been appointed special commissioner for the operators in District 25, to assist in digging out of work accumulated during the recent long conferences over Southwestern and district agreements.

H. L. Warner, general manager of the Victoria Coal Co., has completed a thorough inspection of the mines of the company. D. C. Hitt, sales manager of the company, accompanied by Fred C. McConnell, recently visited the mines of the East Kentucky Coal Co., at Torchlight, Ky.

J. M. Roan, chief mine inspector of Ohio, is receiving subscriptions in the form of money and clothing for the benefit of destitute children and women among the miners' families of eastern Ohio. In many instances the children have been unable to attend school because of lack of clothing.

W. L. Carter, until recently general manager of the Bessemer Coal, Iron & Land Co., of Birmingham, Ala., and since engaged in special work, is now general manager of the Himyar Coal Corporation, at Himyar, Ky. This firm is just completing the installation of a new plant including electric hoists and cutters, reinforced concrete tipples, loading booms, etc.

R. A. Colter, secretary and treasurer of the C. G. Blake Co., of Cincinnati, and of the Waldensia Coal & Coke Co., in his capacity as vice-president of the Cincinnati Chamber of Commerce represented that body at the centennial celebration of the city of Covington, Ky., held recently, appearing formally at an elaborate banquet at which prominent local and state officials were present, and addressing the guests on behalf of Cincinnati.

CONSTRUCTION NEWS

Coshocton, Ohio—The Ohio Cannel Coal Co. expects to open its 5-ft. bed of coal underlying 1200 acres in Bedford Township near Coshocton within the next few weeks.

Providence, Ky.—The Providence Coal Co. is constructing what will be the largest retail store in Webster County for its commissary department. The building is to be of brick, 36x90 ft., with a full basement.

Benz Creek, Penn.—W. H. Hughes & Co. have installed at their No. 1 Slope Benz Creek, Cambria County, Penn., the largest electric hoist in that region. This hoist is driven by a Westinghouse continuously rated 400-hp. alternating current motor.

Williamson, W. Va.—Contracts for the construction of two bridges across Tug River and two miles of railroad up Blackberry Creek have been awarded by the Norfolk and Western Ry., and the construction of this road will open up one of the greatest coal fields in eastern Kentucky.

St. Louis, Mo.—Actual work has been begun on the one-story brick building in the 600 block of Catalan St., to cost $25,000, which will contain the first battery of Koppers by-product coke ovens, for the Laclede Gas Light Co. The entire plant, when completed, next July, will have cost $750,000.

Winchester, Ky.—It is stated that the Consolidation Coal Co., which has been considering driving a tunnel through the mountains that separate McRoberts from Jenkins has ascertained that the opening will be run through 9 ft. of coal and that a sufficient quantity can be thus secured to pay for the work of excavation.

Hazard, Ky.—The Ashless Coal Co. is completing a bridge across the Kentucky River to reach the main line of the Louisville & Nashville R.R. This will follow the completion of a short, three-mile branch road in order to tap an extensive coal field on Davidson's Creek. The company expects to be shipping coal out from its plant within 30 days. There is unusual industrial activity around the Hazard and Perry County coal field.

Lansford, Penn.—The Lehigh Coal & Navigation Co., is now installing at its No. 11 shaft the largest alternating-current equipment used in the anthracite region. The hoist is operated by means of a Westinghouse motor and liquid controller, rated at 750 hp. continuously. The weight of coal, car and cage combined is 28,000 lb. Forty trips per hour are made from the 500-ft. level and 60 trips per hour from the 266-ft. level. The r pe speed being 1300 ft. per minute.

NEW INCORPORATIONS

Chattanooga, Tenn.—The Castlebroom Coal & Iron Co., with a capital of $25,000, has been organized here.

Jenny Lind, Ark.—The Moma Coal Co. has been incorporated here with a capital stock of $3000, by Joseph Moma, J. L. Henson, Max Richardson and others.

Earlington, Ky.—The Atpontley Coal Co. has announced through its president, James E. Rash, and its secretary, Paul M. Moore, that it is winding up its business in order to dissolve.

Williamsburg, Ky.—The Letz-Jellico Coal Co. announces that its business is being closed up and that the corporation will be dissolved. J. W. Latham is president and J. Robert Zimmerman is secretary.

New Albany, Ind.—The Edward J. Hackett Coal Co. has been incorporated here, with $20,000 capital stock, for mining purposes. The directors are Edward J. Hackett, John W. Whedon and S. M. Lawrence.

Charleston, W. Va.—The Hardy Coal Co. of Mullins has been organized with a capital of $100,000. The chief works will be in Parkers Ridge district of Wyoming County. The incorporators are J. C. Sullivan, H. W. Hubbard, J. A. Wood, C. A. Mead, Edward Cox and Frank A. Prince.

Frankfort, Ky.—Articles of incorporation of the Mountain Central Railway Co., which projects a 12½-mile line to run from Campton Junction, Carter County, to Campton, Wolfe County, have been filed with the secretary of state. The company has $25,000 capital and among the incorporators is the Day Lumber & Coal Co., of Clay City, where headquarters will be located. A large coal and timber area will be opened.

INDUSTRIAL NEWS

Chattanooga, Tenn.—The Continental Coal Corporation recently received a cablegram from Brazilian interests asking quotations on 150,000 tons of coal to be delivered at Charleston, S. C.

Cincinnati, Ohio—It is reliably reported that an order from Brazil for 200,000 tons of coal for immediate shipment, presumably for use by war vessels belonging to the Triple Alliance, has been turned down by local companies operating in the West Virginia fields.

Des Moines, Iowa—Matthew Holmes, administrator of the estate of the late John Holmes, asked damages to the amount of $20,000 against the Bloomfield Coal Co. in the district court. John Holmes was killed by a fall of slate in the defendant's mine, and negligence is charged.

Johnstown, Penn.—J. H. Salisbury, of Punxsutawney, and John Harrington, of Horatio, have purchased the Liston mine at Listonburg, Somerset County. Forty men will be employed from the outset with both purchasers taking an active part in the operation of the property.

Washington, D. C.—The people of Alaska may be cut off entirely from their coal supply according to Senator Walsh of Montana. He states that practically the entire supply for Alaska comes from British Colombia and that this province is considering placing an embargo on the exportation of coal owing to European hostilities.

Connellsville, Penn.—According to the report of the State Geological Survey, the total value of the mineral production of Fayette County in 1913, excluding the natural gas, was $38,906,843. This total does not include the value of the coke manufactured, since this was made from coal, the value of which is included in the total given.

Washington, D. C.—Aiming to expand the coal trade with South America during the emergency resulting from war in Europe, the Bureau of Mines recently began the distribution of a bulletin among consumers in Latin American republics describing the coals of the United States best available for export. These bulletins are printed in Spanish, Portugese and English.

Scottdale, Penn.—There has been recently considerable inquiry about the completion of the model coal and coke plant at the H. C. Frick Coke Co.'s Engineering Building. All visitors are welcome to view this model before it is sent to the Panama-Pacific Exposition. This model stands 26 ft. long and 16 ft. wide, and will be on exhibition from 3 to 5 o'clock in the afternoon, and from 7 to 9 in the evening.

Birmingham, Ala.—The Alabama Great Southern Ry. has just equipped all of its engines operating in the Birmingham limits with smoke consumers, in order to meet the smoke requirements. The Southern Ry. is also equipping all of its engines with the apparatus. Several methods of firing were tried in order to reduce the smoke, but without satisfactory results. A jet of steam emitted into the smoke has the effect of precipitating the dust, sending the smoke out in a white cloud.

Chicago, Ill.—The Gun-Crete Co., of Chicago, has purchased all the rights, titles, contracts, and interests in the Cement Gun Construction Co., and has also taken over the Construction Department of the General Cement Gun Co. This enlarges the scope of the business greatly. The combined business will hereafter be conducted under the firm name of the Cement Gun Construction Co. with offices at 914 South Michigan Avenue, Chicago.

Charleston, W. Va.—The Knight Couch Coal Co. recently filed suit in equity in the Kanawha County Circuit Court against the Sunday Creek Co. for $50,000 damages for alleged injuries done to the plaintiff company's mine at Riverside and the recovery of insurance alleged to be due for the houses belonging to the company which were destroyed by fire. The plaintiff leased the property to the defendant and claims that improper mining methods damaged the holdings to the extent of the amount of the judgment asked.

Connellsville, Penn.—Blast furnace operations in the East are on a much reduced scale, and are being still further curtailed. Three stacks most of the production of which has been of the merchant class have been blown out recently. These include Warwick, of Pottstown, Penn., Leesport, of Leesport, Penn., and Musconetcong at Musconetcong, N. J. The latter has been operated on foundry iron for the Singer Manufacturing Co. In Virginia, one active Low Moor furnace is going out leaving but four stacks now in blast.

Pittsburgh, Penn.—English buyers of Pittsburgh products are in some cases closing contracts for the delivery of steel in lighter finished forms. Pittsburgh manufacturers have recently received inquiries and some orders for wire rods of which several thousand tons have already been sold for shipment abroad. Pittsburgh coal men are considering inquiries for fuel from both South America and Europe, but thus far, business actually closed was drawn to eastern mines, which gained the benefit of a lower freight rate to the seaboard.

New York, N. Y.—The commission representing the Italian government that has been negotiating for coal for the Italian navy is reported to have closed a contract for 100,000 tons for prompt shipment, and is still in the market for a large tonnage for future delivery. Coal sales have also recently been made by local firms amounting to about 72,000 tons for export to Greece. Twenty steamships were cleared from Baltimore recently carrying about 100,000 tons, half of which is destined for Brazil, the balance of the shipment being for Mediterranean ports for Greece and one or two cargoes for Norway.

Montgomery, Ala.—The State Railroad Commission has been in session for some time hearing the proposed increases in the coal freight rates, and continued the hearing until this week. After over-ruling the petition of the contestants who believed the time was not ripe for a trial, the Commission refused to continue the case and immediately began the trial. A decision will determine whether or not railroads operating in the Gadsden-Anniston-Talladega district will be allowed to withdraw special manufacturers rates on coal from the Birmingham district, which rates have been allowed for several years.

Washington, D. C.—There seems to be no question but that West Virginia can dispose of her coal in the foreign markets. The Norwegian steamship "Ranvik" and the Greek steamer "Laertes" left Newport News within the past few days with over 14,000 tons of coal for River Plate ports. On Sept. 17, the British steamer "Glenartney" was awaiting cargo for Buenos Aires, the Norwegian steamer "Mathilde" had sailed with a cargo of 3058 tons for Guantanamo, Cuba, and three Italian steamers arrived from ports in the Meditarrean to load for Naples and Genoa. The question which appears to worry coal men at the present time is the permanency of this market.

Connellsville, Penn.—It is stated that during the year 1912, there were imported into Greece 482,768 short tons of coal of which Great Britain supplied 364,996 tons, Germany, 116,035 tons, the rest coming from Turkey, Belgium, and the Netherlands. The total imports for 1911 were 639,822 short tons, while the estimated figures for 1913 show a rapid recovery from the previous year. The imports into the ports of Pirateus for the last twelve months being 665,000 tons including steam and gas coal, etc. The coaling stations in the islands of Zea and Syra received 140,000 tons, most of which was later transferred to ships calling for coal.

Cincinnati, Ohio—The receivers of the Cincinnati, Hamilton & Dayton R.R. have formally filed application in the United States District Court for permission to issue receivers' certificates to the amount of $2,942,250, for the purpose of providing new rolling stock which is declared to be necessary for the proper operation of the road. It is declared in the petition that the present equipment of the road is neither sufficient nor up to the standard. The following new equipment is to be purchased: Five passenger locomotives, 30 freight locomotives, 1000 box cars, 1000 hopper cars, 12 steel passenger coaches, 8 steel combination passenger and baggage coaches, 4 steel combination baggage and mail cars, 5 steel baggage cars, 1 dining car, 1 steam crane, 1 steam locomotive crane and 105 cabooses. All of the equipment except the cabooses, which can be constructed in the company's shops, will have to be purchased, and bids have been received covering it, upon which the amount indicated is based.

Coal Trade Reviews

General Review

Heavy demand for anthracite continues unabated. Bituminous slows down still further and the outlook is now most discouraging. Lake shipments for the season show a big loss. Middle Western steam fuels given away for freight charges.

The anthracite trade is still marked by a steady, persistent call that presages a heavy business this fall and winter. The individuals are offering occasional concessions where some of the slow sizes have accumulated but as a rule full circular prices prevail. In the Lake trade the situation is rather mixed; some shippers claim they have sufficient stocks while others are eagerly taking all they can get. The heavy demand in other directions has absorbed so much coal that the Lake trade has readily taken up the balance.

It is becoming increasingly difficult to maintain prices in the Eastern bituminous trade. Some of the important distributing centers are more or less congested and the markets are steadily narrowing down. Shipments in the export trade are only fair and should there be further recessions along this line it will severely test the resisting powers of the market since these are an important factor in maintaining the present level. A most determined effort will be necessary to avoid a heavy slump in all directions. Rumors are current that shipments on some of the foreign contracts are already about finished.

The opening up of some domestic buying in the Pittsburgh district has been the only bright spot in an otherwise uniformly dull situation. Both railroad and manufacturing demand is light while advance estimates of the Lake shipping to the close of the season place the tonnage at one third less than last year; this latter has been a particularly discouraging proposition with the operators. The attitude of the railroads in refusing to buy beyond their immediate requirements has also proved a depressing factor. Should the rumors of a proposed moratorium in Canada develop into a reality this will tend to complicate negotiations and make the American operators even more cautious.

The heaviness in the Ohio steam market has reached a point bordering on demoralization and the depressing effects are spreading to the domestic branch as well. Production is somewhat reduced as a result of the adverse conditions which are considered by some as the worst in years. The Lake trade is the only encouraging aspect in the Ohio trade; a moderate season-end rush has developed which has created some activity in this department. As a rule the arrivals are in excess of requirements.

Local business in the Southern market is at more or less of a standstill; some small shipments have been made to foreign markets but no important tonnages have so far been reported.

The wide difference between the steam and domestic grades in the Middle West has been further accentuated. The shortage of high-grade domestic fuels created a stampede in that market, culminating in a spectacular advance in quotations. On the other hand operators are in some instances giving the steam fuels away for the cost of the freight or making arrangements to be supplied with side-dump hopper-bottom cars so that the coal can be dumped on the right-of-way. Mines as a rule are probably working on slightly better time. An increased buying movement on the part of the railroads is the best feature of situation at the moment.

ATLANTIC SEABOARD

BOSTON

Export demand slackens and prices on Pocahontas and New River are thought to be on the point of decline. Only a slim market in prospect. Volume of Georges Creek is steadily increasing. Pennsylvania grades fairly firm. Anthracite demand about even with supply, except in the case of stove size.

Bituminous—The indications are that the spot market for Hampton Roads coals is on the verge of a decline. Coastwise, there is practically no business whatever and for some reason the export trade has slackened notably. If this latter continues falling off nothing but the most resolute attitude on the part of shippers can prevent concessions in price in the course of a week or two. For the trade in general such a prospect is disheartening with all the hard work of re-establishing prices, etc., to be done over again. It is not easy to see where any market can be developed in this territory, even at reduced prices, for a long time to come.

In many cases where consumers were ready to buy extra tonnages early in August and their business was then refused by the shippers, particularly from Hampton Roads, they either did not buy at all or they placed orders with Pennsylvania operators. Such business therefore cannot be had now as there is no shortage of Hampton Roads coals.

Georges Creek shipments from Philadelphia and New York continue to improve in volume and not much difficulty is anticipated now in getting forward New England's normal requirements of this grade. Heavy shipments off-shore continue at Baltimore but it is understood that several of the large orders like that of the Greek Government are nearly completed.

There is no new feature in the market for the Pennsylvania grades. Consignees who are fearful of storing summer coal because of possible spontaneous combustion are now accepting deliveries with something like regularity. There are occasional offerings at low prices but for the most part Pennsylvania bituminous is holding firm.

Anthracite—The companies have plenty of September orders now to work on. There is no special delay in shipping, the demand being just about up to the supply on all sizes but stove. Stove is short with most of the companies and schedules calling for more than a third of a cargo are, in some quarters, being flatly declined. There is an active market here for dock screenings but unless the shipments of domestic sizes over the piers increase more than they have lately screenings will continue in short supply.

Current wholesale prices on bituminous are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.90@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.15@2.80	2.50@2.90	2.92@3.02	
New York*	2.40@3.10	2.80@3.20	3.22@3.32	
Baltimore*	.....	.....	2.85@2.95	
Hampton Roads*	.....	.....	.....	$2.85
Boston†	.....	.....	.....	3.63@3.78
Providence†	.....	.....	.....	3.68@3.73

* F.o.b. †On cars.

NEW YORK

Bituminous weaker. No spot demand and some demurrage coal is noted. Anthracite picking up additional strength as the season advances. Heavy Western demand the latest important development.

Bituminous—There is almost a total absence of spot demand in bituminous coal and the market is perceptibly weaker than it has been in some little time. There is, however, little inclination on the part of the operators to force coal on to this market and the amount of demurrage coal

offering is small and prices are fairly well maintained although, of course, here and there a bargain can be had. The higher grades are, generally speaking, well placed under contract so that low prices are confined almost entirely to coals of fair and poor qualities.

The offshore business continues to ease up and there are few inquiries now in the market for export coal. More vessels

are offering and the heavy tonnages available in England are putting this business back into its former channels. The market on slack is very weak. Quotations continue as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania. $2.55@2.65; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

Anthracite—Reports from the West show a heavy movement of crops and the farming interests are beginning to realize on the yield. This furnishes them with money to take care of their coal accounts and is being reflected in the increased demand coming in from the retail dealers. This applies more particularly for rail shipments, Lake movement having been quite heavy and stocks in good shape.

The requirements from the West run about 50 to 60% chestnut, about 25% stove and a small percentage of egg. The heavy demand for chestnut in this direction has a particularly good influence as regards the Eastern market just at this time. In the East chestnut is a size which moves principally in small lots to the cash buyer and for immediate consumption in the cold weather. The Western demand is taking the strain off this market so that there is no druggishness in this size here at present. On the other hand, egg seems to be moving slowly and is being stocked by some of the companies. Stove size continues strong and is getting scarcer. It is practically impossible at this time to buy stove from any of the companies at tidewater without an accompanying tonnage of either egg or chestnut.

The retail situation in New York is quiet, the warm weather of the past few days causing a considerable let up in business. Orders continue to come in, however, from rail points in normal quantities for this time of the year and with any advent of cold weather there is no question that the demand on all sizes will easily take care of the supply with a probable shortage on stove.

The fine sizes continue in about the same condition as last week, the higher grades finding a ready market, whereas inferior coals can be had at considerably off circular. The No. 2 buckwheat does not seem to be as strong as heretofore which is rather an innovation as this size, particularly in high grade coals, has been short almost continually for the past year.

The market is now quotable as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.10	$4.60@5.10	$5.05	$4.55@5.05
Egg	5.35	5.10@5.35	5.30	4.80@5.30
Stove	5.35	5.35@5.40	5.30	5.30@5.40
Chestnut	5.60	5.50@5.60	5.55	5.30@5.55
Pea	3.55	3.50@3.55	3.50	3.40@3.50
Buckwheat	2.80	2.70@2.80	2.50@2.75	2.25@2.75
Rice	2.30	2.15@2.30	2.00@2.25	1.50@2.25
Barley	1.80	1.70@1.80	1.75	1.45@1.75

PHILADELPHIA

Anthracite trade still showing improvement. Restriction of operations has about ceased. Good fall business anticipated. Bituminous indicates slight improvement over last week.

Anthracite—Judging from reports from all sections of the country, the fall and winter demand will be heavy. Operations at the mines have practically been restored to an all week basis, and unless unforeseen circumstances occur, this will continue for the next four or five months at least. Everything points to a successful October, which is generally one of the banner months of the year, as far as actual consumption is concerned. Optimistic reports are coming from both the retailers and wholesalers, which is in vivid contrast to the pessimistic utterances of a month or six weeks past.

While there is still a tendency on the part of the individual operators to make substantial concessions on the slow sizes, taking the market as a whole, prices are well maintained. The exception is chestnut, figures anywhere from 40 to 50c. less than the established circular having been quoted in some instances. Pea coal is also off circular, but not to the same extent as chestnut. Broken, egg and stove seem to be readily absorbed, and stove, as usual, is short of the market requirements.

Tidewater business, which showed a slight falling off in the early weeks of September, is again picking up, and is felt to be the forerunner of heavy business in the near future. Prices rule about as follows:

	Circular	Individual
Broken	$4.75	$4.75
Egg	5.00	4.90 @ 5.00
Stove	5.00	5.10
Chestnut	5.25	4.80 @ 4.90

Bituminous—While the demand for bituminous coal shows a slight improvement, prices are unchanged. Tidewater business is more active than the line trade which is still inclined to be apathetic. Prices for good coals continue about $1.35 to $1.50, with the medium grades from 25 to 30c. less.

BALTIMORE

Slack takes another tumble and demand is generally poor for gas and steam coals. Export trade holds up well. The anthracite business shows strength on domestic account.

Slack during the past 10 days has been sliding, and sales at the West Virginia mines have been made as low as 40c. Run-of-mine coals were offering around 80c., and three-quarter around 90c. Pennsylvania line coals of lower grade were offering below the dollar mark in some cases, while the best grades were to be secured in limited lots at from $1.25 to $1.30.

The one feature that holds up well is the export trade. From two to three steamer loadings per day are being made, and the month's total should be a heavy one. Most of this coal is on old contracts, but there is enough new developing in Greece, Italy, Spain, Norway and the Argentine Republic to make it interesting.

Early in the week, a betterment was noted in the hard-coal trade. The domestic business is showing increased activity, and the movement for household use will be quite heavy within the next two weeks.

A distinct lack of coastwise charters Northward is noted. Several vessels were chartered for Tampa, Galveston and other points South. The Northern movement is almost entirely on long-term charters or in company-owned colliers.

HAMPTON ROADS

Dumpings for the week fair. Large cargoes both coastwise and foreign. Accumulation of coal slightly above normal. Prospects for September indicate a record month.

Dumpings at the various piers have shown up fair during the week but it is not believed that the total will compare favorably with the previous week's movement. Some large shipments, however, have been made, both coastwise and foreign, and in addition the government has also taken a fairly large quantity. Export shipments have gone to Genoa, Naples, Cagliari, Valparaiso, Para, Buenos Aires, Kingston, Port of Spain, Dakar and Piraeus.

Prices for New River and Pocahontas mine-run still continue around $2.85 to $3 but so far as can be ascertained little coal is moving at the latter figure.

In addition to New River and Pocahontas mine-run there have been a few cargoes of high volatile and nut and slack moving to the New England market. The accumulation of coal at the railway yards is perhaps slightly above normal with tonnage about due which will considerably reduce the supply on hand.

Both the Virginian Ry. and Chesapeake & Ohio are already well ahead of their dumpings for this month when compared with a corresponding period of August, and unless there is some delay to tonnage due between now and the first of October the total dumpings for the month of September should be well ahead of all previous figures for Hampton Roads.

COAL CHARTERS

The "Journal of Commerce" reports: The demand holds steady in several of the transatlantic trades, particularly for grain, petroleum, coal and deal carriers, and rates in all instances are firmly supported at the basis of last previous charters. The requirements of West India charters are apparently well covered for the time being, and there is but little inquiry from South American shippers. Tonnage offers moderately for prompt and forward shipment, with rates ruling about as last quoted. In the sailing vessel market a very limited business was concluded, and there was no improvement in the demand for tonnage in any of the several departments. Rates are low and favorable to charterers, and the supply of vessels is considerably in excess of charterers' requirements.

Coal charters have been reported as follows:

Vessel	Nationality	From	To	Tons	Rate
St. Gothard[2]	British	Baltimore	Port Limon	1790	
Glenartney[2]	British	Baltimore or Virginia	Buenos Ayres	3309	
Ranvik[2]	Norwegian	Baltimore	Buenos Ayres or Montevideo	3332	
Themis[2]	Norwegian	Norfolk	Greece	4184	
Confidenza	Italian	Baltimore	West Coast, Italy	2198	
Antares[2]	Norwegian	Baltimore	Havana	1104	
Lovisa	British	Baltimore	Jucaro, Cuba	880	
Alice M. Colburn[1]		Philadelphia	Ponce, P. R.	1335	$1.90
Claveresk[2]	British	Newport News	Havana	2441	
Alice May Davenport[1]		Baltimore	Porto Rico	952	
Childe Harold[1]		Philadelphia	Calais	675	
Pietro[2]	Italian	Baltimore	Naples, Savona or Leghorn	2429	
Thyra Menier[2]		Norfolk	Chandler, Que.	794	
Flora A. Kimball[1]		Philadelphia	Nassau	321	2.50
Edward H. Blake[1]		Port Reading	Camden, Me.	484	0.65

[1] Schooner [2] Steamer

LAKE MARKETS

PITTSBURGH

Slight increase in line trade and buying by retailers but decrease in Lake shipments. Total operations slightly reduced. Prices quite irregular and little new buying.

The local coal situation shows both favorable and unfavorable developments, net balance being unfavorable. The line trade has improved slightly, as compared with a fortnight or 30 days ago, with manufacturing consumers taking heavier shipments. As manufacturing activity has hardly increased it would appear that the change is due to stocks having been still in evidence up to a very few weeks ago. The retail demand has opened up, giving a fresh outlet for coal, and there have been fair shipments to retail dealers for two or three weeks past. The retailers, however, are not taking as much coal as they usually do at this date. The railroad demand is light, and has decreased somewhat.

The Lake trade gives the poorest account. There has been a decided decrease in Lake shipments since the closing days of August. It is true that August showed heavier Lake shipments than July, whereas last year August showed less movement than July, but this year the increase was not large, and the total of August shipments was less than in August a year ago. A rough estimate made by a well posted authority is that the total Lake shipments this year will be about 22,000,000 tons, against 28,000,000 tons last year, the banner year, thus showing a decrease of about 20%. Shipments have been impeded all season by congestion at the Upper Lake docks, the stocks accumulated there last season in anticipation of a prolonged suspension of mining this spring having been moved very slowly.

Mining operations in the Pittsburgh district do not average over 60% at the outside. Prices are irregular and are not closely quotable as there is no contracting and not a great deal of selling of free coal. In general mine-run is not much above a dollar a ton for prompt lots, slack being 50 or 60c. Circular prices for the season are: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.50.

BUFFALO

Slack continues to depress the market. Railroads holding off are also adversely affecting the situation. Canada proposes a moratorium. Anthracite holding strong.

Bituminous—Some of the shippers are inclined to report a better market, but with slack so heavy it is difficult to see anything satisfactory in the trade as a whole. Estimates place the possible fall increase at 20% as compared with 30 or 35% normally. There is at least no present prospect of an advance in prices. The attitude of the railroads is adverse to any improvement. They will not buy a pound of coal where it can be avoided and they are crying poverty so persistently that everybody is affected.

The falling off in the slack trade is thought to be temporary, as there will soon be a big increase in the consumption. There is complaint from the anthracite shippers that the special demand for screenings has dropped off and coke taken up instead; if this is the case screenings will again be used for mixing with slack to make smokeless city fuel; this should make both more active soon. The proposed Canadian moratorium will be taken by all shippers as a confession of inability to pay debts and coal shippers will be still more cautious about selling that market.

The prices of bituminous are weak, but the circular has not been laid aside, some of the best Pittsburgh grades still commanding $2.80 for lump, $2.70 for three-quarter, $2.55 for mine-run and $2.15 for slack, with Allegheny sizes about 25c. lower. One reason for the slow sale of slack is that some consumers are finding a good grade of three-quarter that they consider cheaper.

Anthracite—Shippers with a good supply of anthracite regard themselves as fortunate as the demand has set in strong enough to cause premiums on stove. As a rule everybody is short of this grade. So much coal was sent in some other directions that only 82,500 tons were loaded for Lake shipment during the week. There is some difference of opinion to the needs of the upper Lake docks; some shippers believe that they have about enough there, while others are eager to fill up all available space made by current sales, which are reported good. There will be some caution about shipments to Canada, but as a rule shippers feel that they will be able to arrange for regular payment in spite of the unsettled conditions there.

COLUMBUS

Domestic grades continue heavy and will be a weather proposition from now on. Lake business the only active department. Steam coals slowest in years.

With a slackening in the demand for domestic sizes, due to higher temperatures, a slowing down in steam trade and an active Lake business, the coal trade in Ohio has been almost at a standstill during the past week. Notwithstanding these bad features the tone of the trade has been satisfactory and future prospects are not altogether bad.

The Domestic Trade is largely a weather proposition at this time as the stocking-up season is about over. As a result orders from now on will depend largely upon the temperature. Prices on the whole have been well maintained despite the unfavorable weather.

Lake Trade still retains its activity and a considerable tonnage is moving to the Northwest. Chartering is going on actively and there is a good supply of vessels. Docks in the Upper Lake ports are sending coal to interior points and are thus free from bad congestion.

The Steam Trade is the slowest in years. Manufacturing establishments are not requiring as much fuel as formerly and many have resorted to buying on the open market, rather than to enter into contracts. Railroad fuel business does not show any increase. Many of the larger railroad contracts are still open and the indications are good for a continuation of this condition.

Production in various Ohio fields during the past week has declined to a certain degree. Reports from Hocking Valley district show the output to have been about 75 to 80% normal. In the Pomeroy Bend field the output is about 90% and in other fields about 75%.

Prices in Ohio districts are:

	Hocking Valley	Pomeroy	Kanawha
Re-screened lump	$1.70	$1.75	
Inch and a quarter	1.60	1.60	$1.50
Three-quarter inch	1.45	1.45	1.45
Nut	1.15	1.50	1.15
Mine-run	1.15	1.15	1.15
Nut, pea and slack	0.30	0.35	0.30
Coarse slack	0.20	0.25	0.20

CLEVELAND

Market remains inactive. Current receipts small, but too large for immediate consumption. Orders in the Lake trade have been reduced by leading shippers.

While a few local factories are working only part time or not operating at all, there are some working night and day to supply increased trade due to the European war. The automobile plants, carbon works and clothing industries are very busy, but use comparatively small amounts of fuel. The blast furnaces and steel mills are doing more than they have for a month. Coarse coal is not moving. Nut and slack are readily placed, but pea and bug-dust are refused by the consignees.

Lake Shipping was ordered reduced by shippers who find they will be unable to handle the coal at the upper Lake docks. Large boats of the 10,000-ton class are accepting cargoes to ports where unloading is a matter of a week. Boats of 3000 and 4000 tons usually go to these ports, but the ship managers are so hard up they will carry anything. Freight rates have not been cut.

Prices for current shipment are as follows:

	Pocahontas	Youghiogheny	Bergholz	Fairmount	W. Va. No. 8
Lump	$3.60				
Lump, 6 in.			$2.45		
Egg	3.60				
Egg, 6 in.			2.10		
Lump, 1¼ in.		2.40	2.20		
Lump, ¾ in.		2.30	2.10	2.00	2.05
Mine run	2.75	2.15	2.00	1.90	1.95
Slack	2.40	1.55@1.60	1.55	1.50@1.55	1.50

CINCINNATI

Bad market conditions have spread to the domestic trade. Prices are weakening badly, and while there are some signs of betterment, immediate improvement is improbable.

The poor demand which has been noted in the steam market is now in evidence among domestic consumers and dealers as well. The industrial situation remains poor. Prices have shown signs of a collapse on both sides of the market, concessions being freely offered all around. Nut and slack have been practically given away, in many instances, for several weeks, but heretofore the domestic grades have held firm. That they have now given way to some extent is good evidence of the pressure on the trade. Indications are not lacking, however, that the industrial situation will improve within a few weeks, and that a like improvement may be looked for in the coal industry.

COKE

CONNELLSVILLE

Coke market absolutely stagnant, with consumption decreasing and no occasion for any new purchases, so that prices are practically nominal.

The Connellsville coke market is absolutely stagnant. Consumption is decreasing rather steadily and furnaces in operation are well covered by contracts, on which shipments tend to be excessive rather than otherwise, so that there is no contracting and no demand for prompt furnace coke. The foundries are mining somewhat lighter and foundry coke is also stagnant. Prices are practically nominal, former quotations having been: Prompt furnace, $1.65@1.70; contract furnace, $1.75@1.90; prompt foundry, $2.25@2.35; contract foundry, $2.35@2.50, per net ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Sept. 12 at 250,955 tons, a decrease of 16,915 tons, and shipments at 255,865 tons, a decrease of 14,445 tons.

BUFFALO

It is still considered odd that the iron ore receipts by Lake are so large while the ore trade continues lifeless. It appears from these apparently conflicting reports that ore is going into consumption, while at the same time the consumer is in control of the price of coke. Quotations remain as before, on the basis of $4.25 for best 72-hour Connellsville foundry and $3.30 for stock coke.

BIRMINGHAM

There is no change in the coke market this week, the production being far in excess of the requirements, though prices remain about the same.

SOUTHERN

BIRMINGHAM

No large shipments being made but some tonnage is being exported. Lump coal rather quiet. Furnaces report heavy sales of pig iron.

The demand for steam coal is unchanged though many of the operators state that business has been better. While none of the large tonnages wanted for South American trade have been moved, several shipments of smaller size have been made. One steamer left this week for South America with 2900 tons of coal, and it is understood that another cargo of 7000 tons will leave either Pensacola or Mobile this week. Details regarding charters and finances for the larger export business have not yet been definitely settled.

Lump coal is just about the same as last week, with the production a little larger than the requirements. Blacksmith coal is in a satisfactory condition. Pig iron manufacturers report heavy sales and shipments of iron far exceed the production.

LOUISVILLE

Domestic sizes in good demand but the market is still glutted with the steam grades. Prices unchanged.

The demand for domestic coals is heavy but the retail dealers report they are not doing the business they would like to. Crops are much better than expected and the interior sections will take larger quantities of domestic coals than was anticipated.

The market is glutted with steam sizes, however, and there are large quantities on demurrage, with little in the way of immediate prospects for improvement in the demand. Labor is plentiful and there are some operations running on full time, with markets for all the coal they can produce.

Prices are virtually unchanged except as to the steam sizes, on which cuts are readily made.

MIDDLE WESTERN

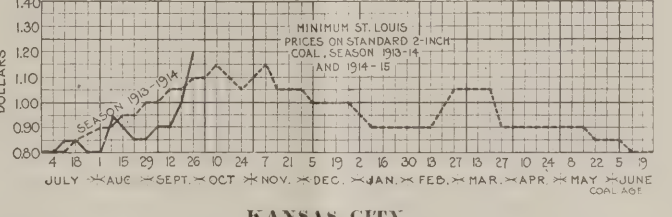
INDIANAPOLIS

Larger movement of freight creates a stronger demand from the railroads. Both steam and domestic consumers doing some stocking. Mines working fuller.

The weather is not favorable to an increased coal trade, yet the retail yards of the state have been ordering the domestic grades freely, apparently in anticipation of the colder weather ahead. There has also been some accumulation by industrial plants for a like reason. Probably the most important feature in the trade now is the improvement in the demand from railroads. This is supposed to be due to the better ocean shipping which has started a larger movement of flour, grain and other commodities to the Atlantic and Gulf ports. Mines are running fuller and a good percentage of the larger operations are on full time. The screenings situation has not improved and low prices prevail in the open market; on this account prices on other grades are held stiffly. Retail prices are unchanged and the movement from the yards is about normal for the season. There are indications of improvement in the industrial situation.

ST. LOUIS

Advance in high-grade domestic coals has developed to spectacular proportions, but the steam coals have suffered a similar decline. Screenings can be obtained for the cost of the freight.



As has been predicted, the high-grade domestic market has experienced a spectacular advance, and the steam trade has gone to pieces. In the Standard field screenings are being given away for the freight, and there is no demand for lump at the price that the operator must have. Failure to move the smaller sizes in the high-grade field has brought about such a congestion at many of the mines that the railroads will not allow them to work until the surplus coal has been sold. This has reduced the working time from five and six days a week down to two days, and the lump and egg produced is not sufficient to care for the contracts alone, in addition to which there is much in the open market already sold. The result is that some mines are still behind on their August shipments of lump and egg, and it is almost impossible to buy these grades for prompt shipment on the open market.

The washed market is good, as far as sizes Nos. 1 and 2 are concerned, but the other grades are dragging. Screenings are down to 20 and 25c. In a general way conditions in the steam market will not improv until colder weather sets in, with a demand for the smaller sizes. There is no hope at all, to bring about a change as far as manufacturing interests are concerned.

In the Standard field the situation is absolutely hopeless. One or two operators in the Williamson County field are already storing their steam sizes close by.

The prevailing circular is:

	Williamson and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump		....	$1.30	$1.20@1.30	$1.25
3-in. lump		....	1.40	....	....

KANSAS CITY

Trade very quiet, the volume falling considerably below normal. Prices are mostly unchanged.

Retail coal trade in Kansas City showed a decided falling off last week. Reasons ascribed are the warm weather which revives recollections of the warm fall last year, and the continued uncertainty as to whether prices will rise materially. Severe storms hampered shipments, but the situation was relieved by the comparatively light demand. Some of the block coal producers have delayed longer than usual in beginning fall operations, and even at that are said to be ahead of the demand. Prices on block coal have advanced 10c. at the mines, but locally are unchanged.

The market is quotable as follows:

	Wholesale	Retail
Block coal	$2.50	$3.75 @ 4
Nut	2.70	3.75
Mill	2.30	3.25
Slack	2.05	3
Semi-anthracite slack		3.75
Semi-anthracite	5.00	6.00

PORTLAND, ORE.

High wood prices expected to increase the demand for coal. Car shortage developing. No coal expected by way of the Panama.

The outlook for this winter is brighter than for some time, that is providing coal will be obtainable without serious delays in transportation. Slab wood is higher than usual this year which is causing an advance to a price where coal will be found cheaper. Many are now placing orders for coal.

Grain is now moving steadily from the interior to the wharves here and on Puget Sound and as a result the railroads are not able to furnish cars promptly.

It is hoped here by the trade that prices will not advance as reasonable coal prices would give them opportunity to introduce coal and gain steady customers who heretofore have favored wood fuel.

PRODUCTION AND TRANSPORTATION STATISTICS

SAULT STE. MARIE CANALS

Coal shipments through the Sault Ste. Marie Canals for July and August were as follows:

	July			August		
	Canal			Canal		
	U. S.	Cana.	Total	U. S.	Cana.	Total
Anthracite	375,127	56,066	431,193	238,952	54,107	293,059
Bituminous	1,580,950	287,200	1,868,150	1,808,341	275,440	2,083,781

PENNSYLVANIA R.R.

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for August and eight months of 1913 and 1914, in short tons:

	August		Eight Months	
	1914	1913	1914	1913
Anthracite	805,585	713,451	7,153,407	6,851,626
Bituminous	4,299,810	4,562,339	31,821,349	33,396,286
Coke	792,656	1,161,484	6,867,676	9,731,462
Total	5,898,051	6,437,274	45,842,432	49,979,374

NORFOLK & WESTERN RY.

The following is a statement of coal handled by the N. & W. Ry. during August and the past four months of the current year in short tons:

	May	June	July	August
Pocahontas Field	1,239,653	1,245,440	1,314,478	1,277,621
Tug River District	263,155	244,342	263,240	293,179
Thacker District	280,148	261,248	288,643	286,572
Kenova District	101,768	97,352	100,600	105,724
Clinch Valley District	150,916	156,028	140,751	134,408
OTher N. & W., Territory	2,596	2,337	2,735	4,211
Total N. & W. Fields	2,038,236	2,006,747	2,110,447	2,101,715
Williamson & Pond Creek R.R.	74,875	76,822	90,819	91,813
All other railroads	225,561	232,387	301,796	257,280
Grand total	2,338,672	2,315,956	2,503,062	2,450,808

Distributions of shipments for July and August compare as follows:

	July			August		
	Shipped	Tipple	Total	Shipped	Tipple	Total
Pocahontas	1,212,483	16,138	1,228,621	1,208,245	14,573	1,222,818
Tug River	260,141	3,099	263,240	289,223	3,956	293,179
Thacker	235,410	7,633	243,043	232,234	9,377	241,611
Kenova	89,953	10,647	100,600	94,494	11,230	105,724
Total	1,797,987	37,517	1,835,504	1,824,196	39,136	1,863,332

Shipments of coke, entirely from the Pocahontas field, amounted to 58,266 tons in August as compared with 62,097 in July.

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic from the New River, Kanawha and Kentucky districts for July, 1913 and 14, in short tons:

	July			
Destination	1914	%	1913	%
Tidewater	262,060	15	238,638	17
East	186,613	10	191,791	14

Total	1,666,854		1,297,301	
From Connections				
Bituminous	133,497	7	93,402	7
Anthracite	878		1,571	
Total	1,801,229	100	1,392,274	100
Coke	25,033		29,945	

FOREIGN MARKETS

GREAT BRITAIN

Market feeling the effects of the curtailed output. Consumption and exports are heavily reduced.

Supplies are coming forward with greater regularity, and the traders are better able to deliver the arrears of coal on order. The low-priced offers to the Government have had a considerable influence upon public orders, and little new trade has been entered into lately.

The market is seriously affected by the restricted output, especially with the house coal collieries, for in many cases working is down to four days per week, and some less than that. Fortunately, however, the weather continues unusually warm, and the actual coal consumption is at its lowest minimum rate. The reports from the collieries all point to a distinct curtailment of labor during the coming winter, arising from the enrollment of so many men willing to serve in the war, and this enlisting is still going on, so that the short-handed feature of colliery labor is likely to become more acute as winter advances.

There are some, however, who prophesy that the export trade is so terribly crippled and is felt more keenly in the North, that there must shortly be a large number of the Durham collieries close down, whilst Yorkshire and Lancashire collieries will endeavor to find home markets for their output, even at reduced prices; and men from these districts are not unlikely to remove into the Midlands, where work is not so much affected by the cessation of the export trade.

Many of the factories along the Thames side—especially those who are dependent upon the import trade for the raw material—have either closed down, or are working very short time. But in other cases, where local industries have been required either for war material or to do with fitting up the various transports, the factories are working at high pressure.

The shipping danger has seriously crippled the oversea trade. Local consumers are taking contract supplies, but producers report a somewhat heavy stock on hand. The same may be said of the North Country coal trade. The demand is good, and especially for the Mediterranean coaling ports, but the difficulty of getting the cargoes safely away is causing a number of steamers to lay up. Freights are nominal, and contract boats and neutral tonnages are easily obtainable at very low rates. Strangely enough, the Humber ports return a very satisfactory tonnage. The market, however, is very quiet, largely on account of the uncertain condition of affairs in the North Sea. The South Wales coal is still largely held by government, and only a comparatively small quantity is available for ordinary sale on the open market.—"The Colliery Guardian."

British exports for August and the first eight months of the past three years were as follows:

	August			Eight Months		
To	1912	1913	1914	1912	1913	1914
Russia	674,546	769,794	169,353	2,515,825	3,794,188	3,049,527

COAL AGE

Vol. 6 NEW YORK, OCTOBER 3, 1914 No. 14

Good Fellows

Written expressly for Coal Age by
BERTON BRALEY

THE barkeeps seem a pleasant lot, they greets yuh with a smile,
They sets the drinks before yuh in a most allurin' style,
And while yer money's plenty they will treat yuh like a king,
But when ye're flat an' busted—why, that's quite a diff'runt thing!

It's "Thank you, sir" an' "How de do?" an' "Won't yuh have a drink?"
An' "Here's to Mr. Miner" when yu've got a lot of chink,
It's "Welcome to our city!" when you've got a tidy sum,
But when the roll is squandered, it is, "T'row him out, th' bum!"

IT'S jolly when yu've finished with yer labor underground
To linger in the barroom where th' bunch is hangin' round,
Where the barkeep hollers, "Howdy" when yuh toss across a bill,
But it's quite another story when yer roll is in the till!

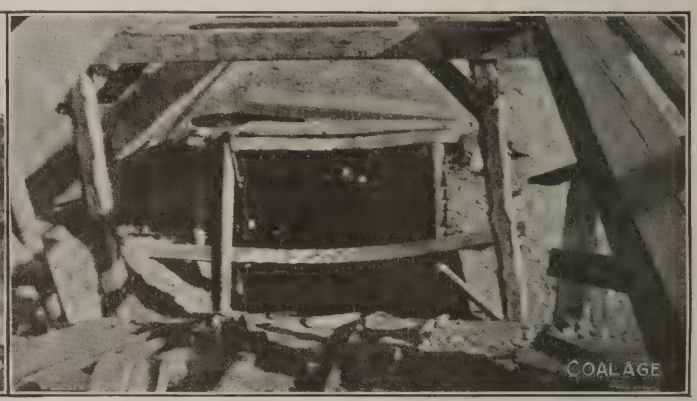
It's "Thank you sir!" an' "How's the boy?" an' "Mister" this an' that,
An' "Welcome to our city!" when th' roll is good an' fat,

It's "Welcome to our city!" when yu've got th' cash to pay,
But it's "Take yer shoes an' beat it!" when you've blowed the cash away!

SO you kin run with barkeeps just as often as yuh please,
But I will keep my distance from such tricky "friends" as these,
They're cordial an' they're merry when there's money in yer poke,
But they go an' call th' bouncer when ye're down an' out an' broke!

It's "Mister" this, an' "Mister" that, an' "Here's to YOU, Old Scout!"
But it's "Git, yuh dirty hobo!" when ye're broke an' down an' out;
It's "Welcome to our city!" when ye're quite amonied gent,
But it's "Bounce th' lazy loafer!" when yer little roll is spent!

A Sudden Squeeze in an Oklahoma Mine



By Geo. M. Brown*

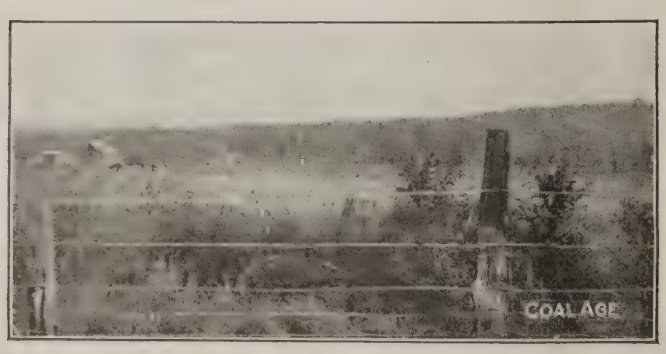
SYNOPSIS—A squeeze suddenly entirely closed an Oklahoma mine which was about to be abandoned, burying 13 men beyond all hope of recovery. An attempt to reach the workings through a neighboring mine completely failed and the bodies of the men will probably never be recovered.

On Friday afternoon, Sept. 4, 1914, an unusual, unforeseen and fatal squeeze took place in Mine No. 1 of the Union Coal Co., at Adamson, Okla., resulting in the death of 13 coal miners and the complete loss of the mine and underground equipment The men are probably buried under 700 ft. of earth and all hope of their rescue has been abandoned.

Mine No. 1 of Union Coal Co. at Adamson, Okla.

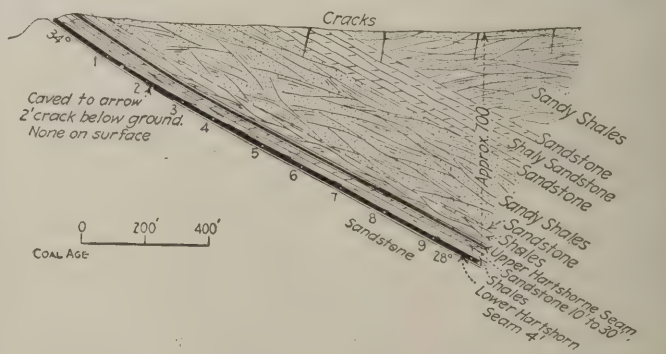
Mouth of Mine, Showing Dead-Line Marks

The mine had been driven down ten lifts and as the remaining coal could be gotten from Mines 4 and 2 on the west and east, respectively, it was to have been abandoned this fall. It was worked on the room-and-pillar double-entry system, chute rooms being driven up the pitch, the dip being about thirty degrees. The slope was driven down the dip and the entries on the strike.



Owing to lack of coal the miners usually cleaned up early and went home. On that account, man-trips were run at noon, at two o'clock and at any time after three o'clock for individual miners. On this day, however, the men worked later than usual and the first man-trip was pulled at 3:53 p.m. These men noticed nothing unusual. The second trip went down to the eighth lift, the first having been to the upper lifts. The men started the mules ahead of the trip as is usually done in Oklahoma and the trip started slowly up the slope. These men noticed the caving down at the slope face but evidently thought of nothing serious. That trip got up at 4:20 p.m. The rope rider refused to go back with the trip, sending it back, however, unaccompanied. It stopped at the sixth lift, and, as the engineer could not move it, the caves had evidently reached that point.

Two Men Race with the Squeeze Successfully



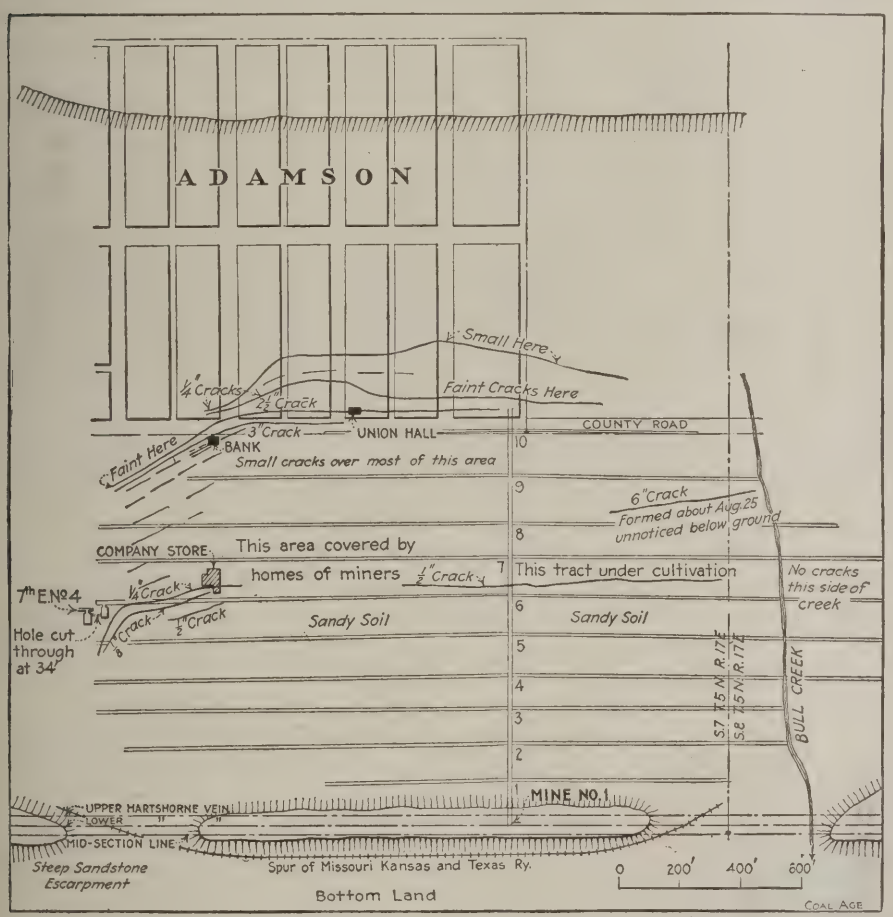
The escape of two of the men was indeed thrilling. The shot firer had gone down and was at No. 3 room on the eighth east entry. He heard the squeezing and ran for the slope, being joined there by a miner. This miner had been at the ninth lift and hearing the caving shouted to the men below to come on out. One man called "Candy Kid" shouted back, "You've got rabbit in you. We're going to wait for the trip. We won't climb out." The trip never came. The shot firer and miner climbed out and as they looked back could see the lights down below but the men had waited too long. At times the caves almost caught the two exhausted men but they finally won out.

Superintendent Mackinnon arrived at 4:30 p.m. and the exits out of the mine being blocked he set men to cut-

*Mining engineer, Osage Coal & Mining Co., McAlester, Okla.

The Lay of the Land North from No. 1 Mine

Cross-Section through Seam at No. 1 Mine



ting a hole through a pillar between mines Nos. 1 and 4. The maps showed 34 ft. of coal and were correct to the foot. The hole was cut through the next afternoon (Saturday). The last cutting brought through so much gas that helmets had to be used. These were brought from McAlester by a rescue party composed of J. J. Rutledge, J. R. Fleming, J. W. Koster and W. T. Burgess, all of the Bureau of Mines. The miners were willing volunteers and everything possible was done. W. E. Beaty, president of the company, was on hand and no expense was spared in pushing the work. The hole was finally widened out and entrance effected on Saturday night.

Rescue Unavailing and Is Abandoned

The rescue party got inside No. 1 mine only 25 ft. and were stopped by a solid wall of slate. The finding of large surface cracks led to the belief that rescue was hopeless and after further investigations by the chief mine inspector, Ed. Boyle, and District Inspector, Martin Clark, it was decided to abandon all hope as the gases released from an upper seam were such as to quickly suffocate the imprisoned men. It is the general belief that the men never got off the slope. The sudden squeezing of the strata would jam the mine doors on the partings so that it would be impossible to open them and the men would be trapped. Evidently there would be no retreating to the face of the slope as the first caves were reported there. The fans and air compressors were run continuously but as the air pipes in No. 1 were hung on timbers they were probably broken by the falling slate.

The condition of the mine was probably as good as the average mine in Oklahoma. The slope was safely timbered from top to bottom. The rooms were turned on 33-ft. centers with a room pillar of from 9 to 12 ft. The top is of sandy shale, 18 to 28 ft. thick, and is considered good. Above this is a stratum of hard sandstone and a little fireclay. Then comes the upper Hartshorne bed 47 ft. above the lower seam, the latter being worked by No. 1. Above the upper seam we find alternate layers of sandstone, sandy and ordinary dark shales.

The surface conditions are as follows: The Hartshorne seams as a rule outcrop along the top of a hill. At Adamson these outcrops lie east and west. The sandstone stratum below the lower Hartshorne bed at the Adamson mines forms a steep escarpment south of which lies low bottom land overflowed by Gaines Creek. North of the crop line the soil is sandy and lies probably twenty feet lower than the outcrops. This area is all more or less covered by timber. About one-half mile north of the mines there is another range of hills about one hundred feet high, composed mostly of sandstone lying below the McAlester seam.

Plan of Mine and Town of Adamson, Showing How Surface Cracks Are Exhibited in Vicinity of Caving

A Large Crack in Front of Union Hall, Adamson, Okla.

The Suddenness of the Collapse

We are accustomed to squeezes in Oklahoma, but generally they act slowly and give plenty of warning. This one, however, was so sudden that it gave scarcely any intimation, and mining men here are puzzled to account for it. It is possible that a fault in the face of the slope extended to the surface and formed a plane of cleavage as it were in the strata. This would throw the whole weight of the overburden on the pillars since there would

be no tendency of the strata to overhang the solid coal. The heavy layer of sandstone would not bend and would naturally prove troublesome. The existence of such a fault on the surface would be hard to find on account of the deep surface soil and sand.

However the accident seems to have been caused by some unusual condition in the overlying strata which mining men here cannot account for. A discussion of similar accidents no doubt will throw light on this unusual occurrence.

From W. E. Beaty, the president and B. E. Clark, the engineer, I received the mine maps and other data which were freely given without hesitation to all who sought for information, and I desire here to express my indebtedness to them for this assistance, without which this article could not have been compiled.

Fighting a Gob Fire by Surface Drilling

By D. H. Somerville and Tracy Garrett*

SYNOPSIS—Peculiar rock formations rendered fighting a gob fire from the mine of little avail. A hole was accordingly drilled from the surface through which water, sand and adobe mud are being poured. All indications point to the success of this method of attack.

At the Weaver mine of the Victor-American Fuel Co., in McKinley County, New Mexico, an effort is being made to quench an old gob fire by means of surface drilling. After years of endeavor, underground, to seal off the affected area and put an end to fire trouble, with no decisive result, it was decided to try a new method, one conceived by W. J. Murray, vice-president and general manager of the company, as early as January, 1911, but which was not attempted until March of this year.

A drill hole was put down from the surface to the fire zone, 291 ft. below, and through this hole tons of water, adobe mud and sand are being dumped. The work is not yet completed but, thus far the results have all been favorable to the new method and the indications are that the outcome will be a complete victory over the old enemy of the mine.

That there may be a thorough understanding of the conditions existing, the difficulties encountered and the work done, a brief description of the fields and coal may be of interest.

General View of Dredging Machinery at Bore-Hole

The mines in this field are working two different series of lignitic, noncoking coals, known as the upper and lower measures. Both are in the Laramie Cretaceous beds. The two measures are separated by from 500 to 800 ft. There are in the upper group five distinct veins, known as Nos. 1, 2, 3, 3½ and 5, but at no one point in the field are all of these veins workable.

At the Weaver mine, when it was opened, three of these veins were workable, but on going back into the field, but two of them can be operated, namely Nos. 3 and 5. Toward the outcrop, however, Nos. 3 and 3½ were worked extensively. The distance between the Nos. 5 and 3½ runs about 26 ft., while that between Nos. 3½ and 3 runs only about 6 ft.

The strata between these two veins are so thin that it has always been difficult to work out both measures successfully. If the upper of the two, the No. 3, was worked first, the lower measure would heave the bottom and, if the lower of the two, the No. 3½ vein, was worked first, the upper would cave the roof so that, in some cases, it was apparently necessary to leave much coal in the gobs.

The coal thus left in the gobs fired spontaneously, and this was the condition when the Victor-American Fuel Co., the present operator of the mine, took over the property from the former owners several years ago.

To Seal the Fire Off Was Difficult

As there is very little cover over the coal near the outcroppings and consequently many surface breaks, through which air could travel to support combustion, there has been no end of trouble, at different times, in endeavoring to seal off the burning area.

The roof over the No. 5 vein, in fact, the whole strata between it and the No. 3½ vein, is a mixture of sandy shale and fireclay. This increased the difficulties under which those engaged in the work of sealing off the fire were forced to labor. In some cases breaks in the roof of the No. 5 vein would extend through to the No. 3½ and No. 3 veins, which are now old workings.

At one point in the workings of the No. 5 vein, the fire traveled through these crevices and reached down into the lower measure. This happened in a crosscut between a pair of entries. A considerable part of the roof had fallen in this crosscut, almost to the upper vein where the fire was, before it was noticed.

Concrete walls were then built alongside of these entries and these were connected by similar walls built through the chain pillar at both the upper and lower ends of the side walls. The main entry was then arched and thus the fire in the No. 5 vein was confined to a comparatively small area. Considerable difficulty was, however, experienced in doing this and in shutting off the air,

*Victor-American Fuel Co., Gibson, N. M.

as the concrete would crack with the heat, making continual work, watching and expense.

It was then decided to attack the fire by surface drilling and arrangements were immediately made to sink a hole to a point directly over the caved area in the fire zone.

The point on the surface thus selected for operations was not readily accessible for heavy drilling machinery and a light, churn well drill was selected for the work, the power being a gasoline engine, the only rigging being a gin pole instead of a derrick. The drill was equipped with a wire cable instead of the hemp rope usually used on apparatus of this character on account of the heat to be encountered.

Drilling began on Mar. 6, and a 6-in. hole was put down. At 250 ft. the heat became decidedly noticeable and gave warning that the fire was not far below the bit of the drill. From this point on, steam and gases arose and, though a 1-in. stream of water from a pipe line that

Introducing a Charge of Adobe Mud into the Pipe

had been laid from the camp tanks, was continuously discharged into the hole, the bit, when pulled, was invariably too hot to handle without gloves.

A telephone line, connecting with the mine telephone system, was strung to the drill and the men on the surface kept constantly in touch with those on the inside. There was much speculation as to just what would happen when the drill went through onto the fire and when the first water and mud were poured into the hole. For this reason, it was thought best, in the interest of safety to keep all men, except those actually engaged in the work in the troubled area, out of the mine until it was definitely determined that there was no danger of an explosion of steam or a sudden spreading of smoke or gases. This was done, although, as it fortunately turned out, the precaution was unecessary.

The Drill Hole Was Cased

The 6-in. hole was cased with a 4½-in. casing, which was extended down to the cave. Into this casing a smaller pipe was inserted with packing around same and a valve at the top. A barrel, to act as a funnel, was placed on top of this latter pipe, a short nipple connecting the barrel with the valve. A larger pipe line was laid from the water tanks and a mixing box placed in such a position as to empty into the barrel by means of a suitable trough.

To prevent the air from reaching the fire by way of the hole, the plan followed was to make a mixture of sand, adobe and water in the mixing box, run this into the barrel until the latter was filled, keeping the valve closed, then, opening the valve, allow about three-fourths of the contents of the barrel to run through the hole, the mixture remaining in the barrel, shutting off the air until the valve could be closed again.

A large quantity of sand was used at first, but it was found that the sand did not mix and flow readily with the water and that adobe, when mixed very thin, flowed much better. Consequently a thin mixture of adobe and water has been emptied into the hole night and day for nearly two months, to the present writing, at the rate of about 12 tons of adobe in 24 hours.

Occasionally, the barrel would be filled with water only, several times in succession, and this allowed to run into the hole to wash away the adobe that would collect and cake at the bottom, owing to the great heat. Several times, also, it was found necessary to again drop in the drill to clear out the hole.

As the lower part filled up, the casing and pipe were raised until they reached the No. 3 vein. While a quantity of water comes through the roof and runs into the mine, the amount thus entering is not alarming, in fact not as much water is coming through as was expected and, though a careful watch is maintained both day and night underground, thus far there have been no ill-effects in the mine from the hundreds of tons of mud and water that have been poured down the drill hole.

Of course, at this time, it cannot be definitely determined whether or not this method of fighting the fire will be entirely successful, but, as the temperature in the troubled territory has been practically cut in half, there is every reason to believe that the final result will be all that can be hoped for.

In the accompanying illustrations, the nearer view shows the barrel used as a funnel and attached to the valve which, in turn, is attached to the pipe within the casing. The mixture of water and adobe is being poured into the barrel from the mixing box and the man at the valve is just opening it to allow the mixture to run into the hole. The other illustration gives a general view of the drilling machinery and engine.

Coal for Sicily

In the *Daily Consular and Trade Reports,* under date of Sept. 24, American Consul Samuel H. Shank, located at Palermo, Italy, in commenting on the Sicilian fuel needs says in part:

In the past, England has supplied almost all the coal for Sicily. In 1913, the total imports at Palermo amounted to 211,680 tons, of which 206,470 came from England. The United States supplied only 5210 tons.

Present indications, however, would seem to be favorable for American exporters to get a start here, which should eventually give them a share of the business. It is difficult to get consumers to change from one coal to another, but should the war continue, it may not be possible to get a sufficient supply from England.

Cardiff and New Castle coals are used more than any other. Some anthracite is shipped from Swansea. The greatest amount of coal is used for steaming purposes and for manufacturing gas. Very little coal is used by private individuals, as most of the cooking and heating is done by gas or charcoal.

The usual price of Cardiff coal has been $6.80 per ton, c.i.f. Palermo, and for New Castle $5.60. The freight from England has in the past been $2 a ton, and there is no duty.

Many inquiries have been made at this consulate, and one concern has cabled to the United States for prices. Persons interested in the matter should send analyses of their coal, and quote prices if possible c.i.f. Palermo. Proposals may be directed to this consulate, in which case they will be put into the hands of the parties interested.

Coal-Cutting Machines in the Anthracite Region

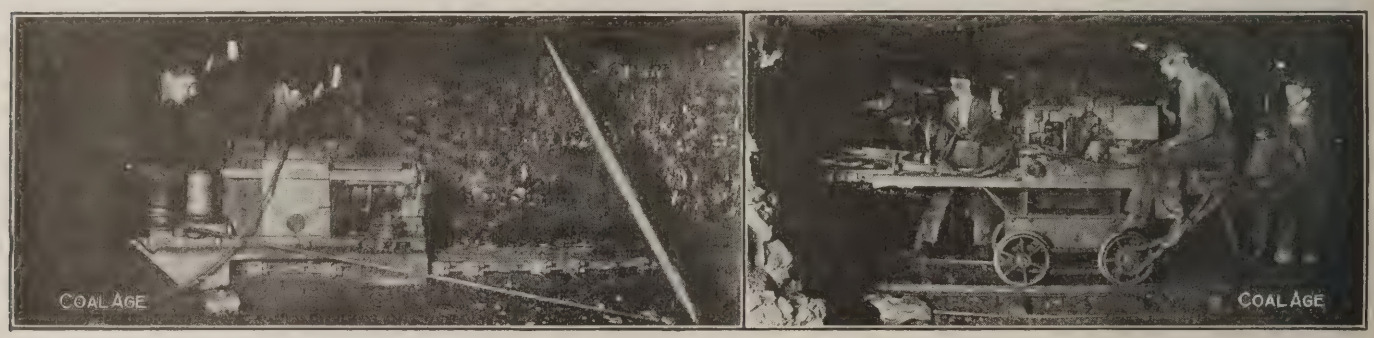
By M. S. Beddow*

SYNOPSIS—The chain undercutters used with success in bituminous coals had to be redesigned when subjected to the heavier stresses incident to operation in anthracite. These machines are, however, doing much to render profitable the working of thin coal measures.

Four or five years ago, had a person mentioned coal-cutting machines in connection with anthracite mining, he would have been laughed to scorn. These have, however, been given a fair trial and except for a few minor details have not been found wanting. Mechanical cutting of anthracite has ceased to be an experiment, as operators throughout the entire field have come to believe that it is the only successful way in which to mine the thinner, and hitherto unprofitable coal beds.

Nor is the use of mechanical cutting confined to coal measures of only 28 or 30 in. thickness, although it is quite true that it is here that the chief benefits are derived, due to the large amount of rock which formerly had to be removed as compared to the tonnage of coal secured.

After proving conclusively that chamber, or short-wall, mechanical cutting was perfectly possible, further experiments were conducted along the line of long-wall mining. Here also success was secured. Under the old method of mining some of the smaller coal beds, it was found necessary to remove four or five feet of rock in order to secure about half that thickness of coal. At the present time, however, this rock save in the gangways and airways is allowed to remain.



During the experimental stage when each coal-cutting machine manufacturer was anxious to "make good," it was discovered that if mechanical cutting was to prove a success, a number of changes would have to be made in the machine design. In other words, the coal cutters as they were turned out for use in soft-coal measures would not answer for use in the anthracite field.

In the first place, the chisel-pointed bit, which is exactly what its name implies, was found to take too great a bite in the coal, and was therefore liable to place an excessive load on the motor. The pick-pointed bit was then adopted, and is now doing effective work almost universally. Furthermore, the cuttings or "bug dust" made by a chain using this latter type of bit is not nearly as fine, as when chisel-pointed bits are employed and consequently contains a larger percentage of salable sizes.

This fact is apparently insignificant, but the smaller the coal which is produced at the working face, the less chance there is of its reaching the breaker where it is prepared for market, since, the small stuff, is lost through the crevices in the cars on its journey to the foot of the shaft. A large percentage of this dust, however, which does reach the breaker is made into buckwheat and smaller sizes, the profit from which is, to the producer, negligible.

The Cutter Bar Was Weak

The next difficulty encountered was with the cutter bar around which the chain carrying the bits above referred to revolves. In particularly hard measures, the bar as constructed for soft coals has been known to bend badly. This part of the machine was accordingly enlarged and its quality improved. Other alterations, such as stronger cutting chains, bits harder tempered, heavier gearing etc., were made before the mechanical end of the machine was satisfactory.

A Morgan-Gardner Mining Machine Making a Sumping Cut and Entering a Chamber under Its Own Power

It will be at once perceived that the above reinforcement would necessarily compel a corresponding change in the electric drive. A marked increase was shortly noticed in armature, field, controller and resistance troubles, but the remedy was not as simple and easy as in the former case, since it required more time and thought to alter a whole motor equipment and its accessories, than to strengthen a partially weak mechanical equipment.

The electric drive, had, like the cutter bar and chain, been originally constructed for operation in soft-coal measures, consequently, when it encountered the harder anthracite, the current taken by the motor increased in direct ratio with the increased difficulty in cutting. When it is considered that the heat generated in the armature and field winding increases with the square of the current, one is enabled to understand how much extra heat had to be dissipated, even supposing that anthracite cutting is only twice as hard as bituminous. An increase in motor rating from 30 to 50 hp. shows how the difficulty of cutting increased in passing from the soft- to the hard-coal regions.

*Scranton, Penn.

Two Methods of Cutting Employed

There are two methods of cutting in use in the anthracite field. These are the chamber, or short-wall, and the long-wall. In the former, the machine enters the working place, passing from the truck to the extreme right-hand rib. It then sumps the full depth of the cutter bar, the length of which ranges from 5 ft. 3 in. to 6 ft. When the sumping cut is complete, the machine is drawn across the face of the room to the opposite rib, this being accomplished by means of a cable or chain attached to a jack at the left-hand side of the room. The speed of cutting is from 12 to 18 in. per min., while the places vary in width from 26 to 30 ft.

As above stated, the actual cutting is done by a rapidly moving chain which carries a series of bits, which are turned at different angles to the plane of the cutter bar. The bits are so positioned that the width of the cut is slightly greater than the thickness of the bar so that the latter moves freely under the coal, placing no extra strain on the driving mechanism.

Cutter bars as now employed range in thickness from 2½ to 4¾ in. and the bits in order to give clearance for the bar cut a kerf slightly wider than this. After the undercut is complete, the machine pulls itself back onto the truck, and, under its own power, moves to the next room or chamber where the same operations are repeated.

After a place is thus undercut, and the machine and its operators have passed on, the place is turned over to the miner and his laborers who proceed to drill the necessary holes, blast down the coal and load it out into mine cars. The rock is then removed from a sufficient width and depth to allow the advance of the rails, cars, mules, or locomotives, as the case may be. This rock is also loaded into cars, or where there is sufficient room gobbed. In this respect, the long-wall method has the advantage, for the rock, save that in the gangway and airway, is here allowed to remain.

In the short-wall, or chamber method of mining, the track must follow the miner the complete length of the room. This necessitates the removal of sufficient bottom rock to give clearance for the car. It will, therefore, be easily seen that the cost of removing this dead material is sometimes enormous. Furthermore, this must be done in each chamber or working place in the mine.

There Is Less Dead Work with the Long-Wall Method

In the long-wall method of operation, the rock on the main gangway only is removed to give a total height of about 6 ft. The machine undercuts along a face 215 ft. in length, and this entire amount of coal is then drilled and shot down. An endless-chain conveyor driven by a 10-hp. motor is operated along the base of the broken coal. The latter is loaded into this conveyor, which transports it to a waiting car on the gangway.

When the conveyor is fully loaded, and the motor which drives it is running at its highest speed, a car can be filled in from two to three minutes, depending upon the car's size. Enough coal is undercut in the night shift to supply the loaders with plenty of work for the next day.

This performance is repeated day after day, a pillar of coal being left only when the roof becomes so unmanageable that the cribbing fails to hold it in check. In this event, the entire face of the long wall is removed to a point about 30 ft. in advance, the intervening coal being left to support the roof, which settles evenly on either side until it again finds a resting place.

It is not often that this inside disturbance is felt on the surface, for due to the system of cribbing employed the roof only settles for about 30 in. and that quite evenly. From 60 to 70 cars are obtained per day from a long-wall face of the length above mentioned.

In closing, I wish to bring out a thought which has not hitherto been mentioned in this consideration of methods of cutting anthracite coal; this is the evident decrease of accidents of all kinds which has acompanied undercutting as compared with shooting the coal from the solid. Formerly where coal was extremely hard, requiring heavy shots, large pieces were frequently blown for considerable distances, and sometimes carried destruction in their paths. With the present methods, the natural tendency of the coal is to fall from its own weight, and it is seldom that, even under the action of the explosive, it leaves the chamber proper.

I predict brilliant future success for coal-cutting machines and methods in the hard-coal fields.

Cables in Bore-Holes

By C. M. Means*

Bore-holes offer a safe and convenient method of transmitting electric power from the surface to the underground. Cables can be caried on the surface and down a bore-hole located at or near the point where power is actually required and at such voltages as best suit the conditions. Circuits having potentials up to 6600 or even 13,000 volts can be handled safely in this manner. To attempt to transmit power at these high voltages along headings underground would introduce an element of danger or the cost of installation would be prohibitive.

The advantages are in favor of a bore-hole for this purpose, as compared to any other method, whether the mine be a drift, slope or shaft operation. In small drift mines, this might not apply but if the mine covers any extensive area or requires considerable power, the bore-hole method of entering the workings with electric conductors is to be recommended.

Except in the case of great depths, a bore-hole should be used at shaft mines and should be so located that no main conductors would be near the bottom of the shaft, which is usually congested.

Cables supported in shafts introduce a certain element of danger from fire or accidental contact by persons working in their vicinity. Furthermore, the cables are in an exposed condition and subject to mechanical injury.

Cables properly installed in bore-holes offer a higher factor of safety and reliability than is secured by any other method. There have been a number of failures of cables in bore-holes, but in the cases investigated the difficulty was found to be due to improper installation and not defective cables. The manufacturers are in a position to produce cables with a high factor of safety, but all their skill and care in manufacture are lost if the bore-hole is not properly arranged for the service or the cables be not properly supported.

A cable in a bore-hole will have the same degree of reliability as a cable installed in a similar length of pipe or conduit on the surface, if a good bore-hole is provided, and the cables supported in a proper manner.

The casing in such a bore-hole should be of sufficient

*Randolph-Means Co., Pittsburgh, Penn.

size to contain all the cables necessary without crowding and should be smooth on the inside so as not to cause abrasion of the conductors while they are being lowered into position. The casing should, therefore, be prepared in the same manner as iron conduit used on the surface for a similar purpose.

All joints should be made waterproof so that no water even under pressure can leak to the inside. Sufficient space should be left around the pipe to allow at least one inch of concrete to be placed between it and the inside of the drill hole. It is important that this concrete be continuous throughout the entire length of the pipe. Care should be taken around the bottom of the hole to see that the concrete shuts off all moisture and when the hole is complete no water should leak from the strata around the pipe.

The method of support will vary with different installations, depending on the depth of the hole and kind of cable used. With holes up to 500 ft. in depth, no difficulty should be encountered in securing a proper support for any cable, but beyond this length they should be specially designed for the work they are to do.

Cables insulated for the required voltage with good weatherproof covering have proven highly satisfactory where properly installed. Ordinary lead-covered cables have no place as conductors in a bore-hole because of the difficulty of support. Special armored cables are desirable for the higher voltages, but in every case should be designed for the particular work required of them.

The weight of low-voltage cables is largely represented by the conductor and this has sufficient tensile strength to support quite long lengths. If the factor of safety is not great enough with soft-drawn copper, this can be increased by using hard-drawn wire, aluminum or a steel center. For all low-voltage work, single-conductor cables are preferable.

In many cases, it will be found advantageous to use single conductor weatherproof covered cables for high-voltage installations, supporting their weight by the conductors themselves. Armored cables should be employed where multiple conductors are desirable and the armor utilized for supporting the weight.

If it is desirable to hang an armored cable at more than one point, the supports must be equalized so that there is no danger of the total weight coming on any single point of suspension. In general, the conductor should be designed for only one point of support and this can be accomplished by using a proper cable.

Cables in bore-holes should be subjected to frequent inspections, and examinations made for leaks or moisture, as it is important that the inside of the bore-hole be kept dry at all times. Air should not be allowed to circulate therein unless the temperature of the air going into the pipe is lower than that of the walls. Bore-holes can be dried out during the winter by allowing cold air to pass down the holes, as in expanding it will take up the moisture.

The use of single-cable conductors is suggested because of the ease of repairs. At the ordinary mine, material is usually kept on hand wherewith to make repairs to the ordinary insulated cable with weatherproof covering, but few operations have the facilities for repairing armored cables.

Inasmuch as a single bore-hole is often depended on for the entire supply of power to a mine, it is not only important to have a high factor of safety, but the entire design should be such as to admit of easy and quick repairs in case of an unusual accident.

Extracts from a Superintendent's Diary

Whenever I visit the city and am pursued by the numberless beggars flaunting deformities of every imaginable description, I am always reminded that I have yet to see my first beggar at a mining camp.

We have plenty of cripples and dependents, but the generous spirit of the community somehow always relieves these unfortunates from the necessity of begging. The same statement could probably be made of any restricted community. If all vagrant beggars could be persuaded to continue their residence in the place where misfortune overtook them and reduced them to a state of justifiable beggary, there would soon be no beggars. We have not yet become so niggardly that we neglect the unfortunate whose life history is familiar to us.

Some people use this line of reasoning to prove that all beggars are impostors, but I cannot agree with them. Unfortunates, like all other classes of human beings, sometimes are possessed by the wanderlust and naturally, when one who is unable to earn his living finds himself out of reach of kith and kin, he becomes a beggar automatically.

Such a one was buried in our town today.

Ten years ago Tom Flemming was an average coal digger. Then he walked back on a dynamite shot in his heading and found himself minus one arm and both legs, after the surgeons dismissed him from the hospital. The following year he received $2000 in court and remained on a spree for about six months. Within two months' reckoning from the day he became sober, he was penniless. But he was not compelled to beg. One of the small merchants on the edge of the camp decided to handle explosives and put Tom in charge of the sales on a commission basis. This was a strictly commercial proposition and it proved to be a good business deal for the merchant. For several years Tom's earnings were in excess of his previous earnings as a miner.

In the early part of his life, Tom had been a great wanderer and now that so much of his time was unoccupied, he thought often of his early experiences and the places he had visited and the people he had known.

If the men who bought their supplies from Tom could have read his thoughts during this period, the final tragedy in his life could probably have been averted, but they did not and so one fine spring morning Tom did not report for work, but instead, started off on a long journey.

For a time we had tidings from him in round-about ways, but eventually he got out of touch with everyone he had ever known.

Again he capitalized his deformities, this time as a common street beggar. Back home when the boys patronized Tom because of his infirmities, they did not allow him to feel that sympathy had any part in the transaction, but now his patrons had no scruples in the matter. In fact, they were constantly asking all kinds of questions and expressing all kinds of doubts before offering their pitiful pittances.

Poor Tom had only one hope remaining and that was to be buried back home.

Just how he managed to get back remains a mystery.

The Proving of Mine-Rescue Apparatus

By R. Dawson Hall

SYNOPSIS—An account of an instrument for testing the condition of mine-rescue apparatus, not in an emergency but at regular intervals.

The value of mine-rescue apparatus depends entirely on the condition in which it is kept. If it is allowed to get out of order, when the time comes to use it, it will not be available. The tests should be made, therefore, at regular intervals, and these should be more thorough than those used prior to actual mine-rescue work, which are necessarily hurried and superficial.

The meters illustrated below test all the parts of the breathing apparatus. Mounted on a common stand they

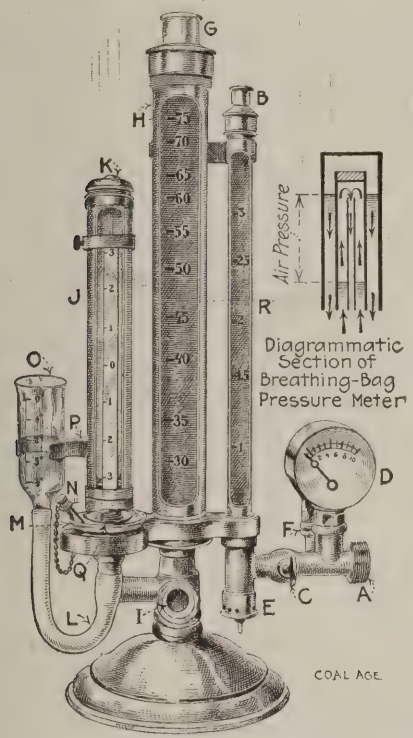


Fig. 1. Instrument for Testing Breathing Apparatus

are conveniently available; no parts are likely to be lost and no tests are apt to be overlooked.

The Quantities Needing Measurement

Such an apparatus should test (1) the quantity of oxygen which the reducing valve delivers, (2) the pressure at which the oxygen is delivered, (3) the amount of air which the injector will draw through the apparatus, (4) the pressure under which the air circulates, and (5) the pressure at which the relief valve of the breathing bag will lift. There is an appropriate meter supplied to prove all these various characteristics.

The tube *R* and the pressure gage *D* on the right, Fig. 1, are for the purpose of testing, not the working of the apparatus as a whole, but simply the action of the reducing valve of the oxygen cylinder, to ascertain whether that valve passes the needed amount of oxygen and delivers it at the correct pressure.

To prevent the reader from misapprehending the functions of the various parts, we have illustrated that section of the breathing apparatus which is tested with the part of the testing device by which it is measured, omitting all other parts. It may be stated, however, that the apparatus as built cannot be thus divided physically into various parts.

Volume of Oxygen Passing

The reader should now concentrate his attention on Fig. 2. The end of the air-supply hose where it normally enters the breathing bag is screwed on the connection *A* of the testing apparatus. The cap *B* is removed and the cock *C* opened wide. The opening by which, under normal conditions, air is admitted on the side of the injector, is closed by screw cap *S* and the valve is opened to the oxygen cylinders. The oxygen is thus

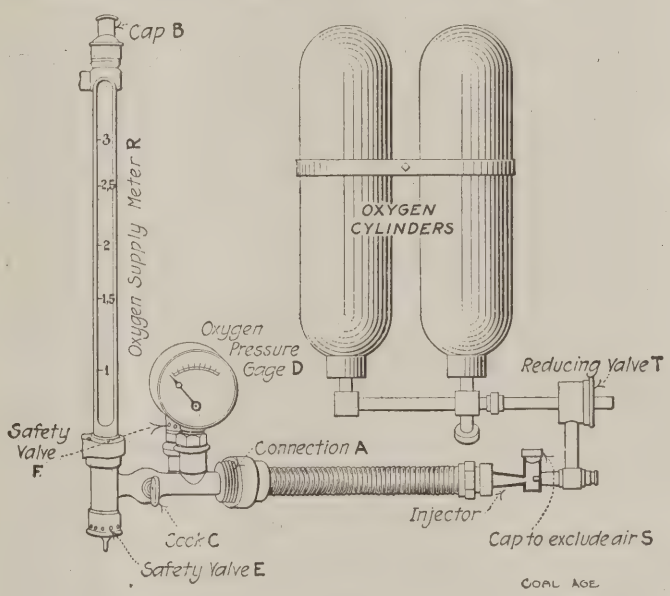

Fig. 2. Connections When Measuring Oxygen Supply and Pressure

able to pass from the oxygen cylinders, through the reducing valve *T*, the injector and the air-supply hose into the testing apparatus. It cannot, of course, in this passage augment its volume by drawing in air, because of the screw cap just referred to. This oxygen has sufficient volume to lift, in the oxygen-supply meter *R*, a small truncated cone, which measures by its rise the quantity of oxygen thus passing. The oxygen delivered should be two liters per minute and the spheroid should stop with its upper edge at the figure two. The tube of the meter is graduated so that the amount of oxygen passing when between one and three liters per minute can be accurately determined. It is absolutely essential that the cap *B* be removed, for the mensuration depends on the movement of the air and moreover the glass of the meter is not strong enough to sustain the full pressure

delivered by the reducing valve. There is, it is true, a safety valve at *E*, but the experimenter should not rely on it to remove this pressure.

Pressure of Oxygen as Delivered to Apparatus

For the next test, that of the pressure of the oxygen delivered, the arrangements are identical, but as the static pressure is far greater than that reached when the oxygen is allowed to pass away unrestrained, an armored tube, capable of sustaining a higher pressure, is used instead of the regular air-supply hose to lead from the injector to the connection *A*. The cock *C* should be closed. Be sure that the cap *B* is not replaced till the cock *C* is turned against the entrance of air. In fact the function of the cap *B*, which is to keep the apparatus clear of dust when the oxygen supply is not being tested should be kept in mind. It is no more an integral part of the apparatus than the box in which the whole device is packed.

The oxygen being prevented from escaping by the closing of cock *C*, the oxygen-pressure gage *D* shows the pressure supplied by the reducing valve in atmospheres. This should read about 6 and if it does not the reducing valve should be adjusted and the flow of oxygen redetermined.

Volume of Air in Circulation

The central tube of the metering device, Fig. 1, we are describing, measures not the oxygen but the air and oxygen combined, that is, the enriched air circulating in the apparatus. Fig. 3 represents the arrangements for such measurement. The cap *G* is removed on the top of the air-supply meter *H*, and the end of the air-supply valve is screwed to the connection *I*. The cap *S* which was placed in the first tests over the air inlet in the side of the injector is, of course, removed. The air and oxygen entering the glass air-supply meter *H* raises a truncated cone within it, which measures the quantity passing. This should be from 50 to 65 liters per minute, the glass face being graduated to read in those units. The test may be made with the entire apparatus connected up so that the air drawn in must pass through the exhalation and air-discharge hoses, the regenerator and the cooling tube. This will interpose some additional resistance and the injector will, therefore, provide less circulation.

Pressure Producing Air Circulation

The pressure in the breathing bag is measured with the same connections. The oxygen supply is first cut off, however, by closing the valve of the oxygen cylinders, and after removing the cap *K*, the meter *J* is filled with colored alcohol or colored distilled water to about its mid-position, and the cap *K* replaced. There are three concentric tubes in this part of the apparatus. The liquid enters the outer tube, and rises from the base of the middle tube till both are filled to the same level. This middle tube is closed at the top and the air escapes by the innermost tube, as shown diagrammatically on the right of Fig. 1. An adjustable scale is set to read zero at the water level. On opening the reducing valve, the air entering at the innermost tube presses the liquid down in the middle tube and raises that in the outer, the water column thus created balancing the pressure of the air. The readings above and below the zero added together give the pressure of circulation which should be about 3.9 in., or 10 cm. Similarly the suction can be determined by connecting the breathing-bag pressure meter with the discharge hose.

Why the Relief Valve Should Be Sensitive

It is important that the relief valve in the breathing bag prevent the air pressure from becoming too high or from discharging till the pressure reaches the required figure. For if the pressure at which the valve operates is too low, the breathing bags are liable not to be sufficiently filled with air and breathing will be difficult. Some claim that the pressure in the bag should not be too low or otherwise if there are any invisible leaks in the apparatus, carbon monoxide may pass in when the wearer

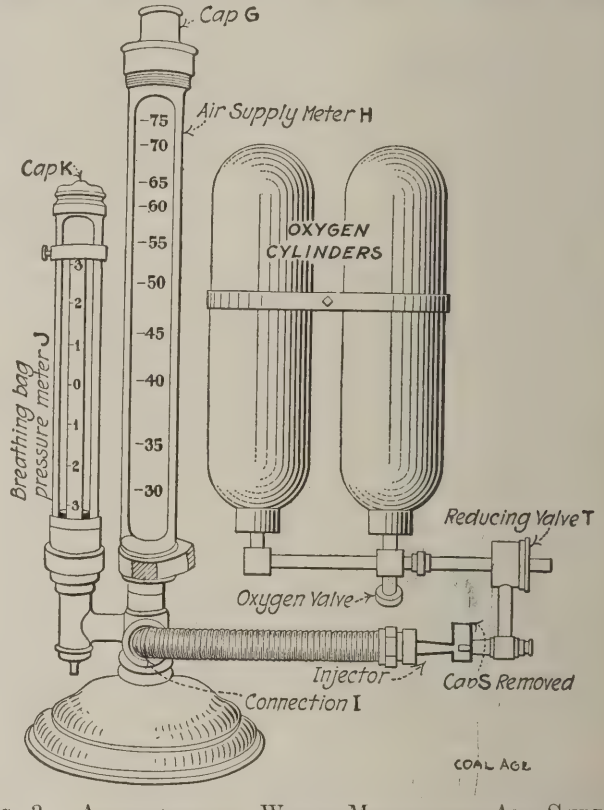

Fig. 3. Arrangement When Measuring Air Supply and Pressure

is working in an atmosphere where such gas is present.

Nor is excessive pressure desirable, as exhalation will be difficult and the effort will exhaust the wearer. It is desirable that he have the minimum resistance which is necessary for safety in breathing in and breathing out. The relief valve is intended to regulate this and its sufficiency as a regulator should be measured.

Testing the Relief Valve

To measure the pressure at which the relief valve will discharge, a relief-valve meter *O* is placed on the side of the apparatus. This is connected by a rubber tube *L* to a dish *M*. In the center of the dish projects the end of a metal tube *Q*, which is open at both ends. This tube is connected at its lower end with the rubber hose *L*. No connections are made with the apparatus. Only the relief valve is disconnected and tested when the meter is ready for operation.

The measuring glass *O* is lowered in the bracket *P* till the zero point of the scale on its side is level with

the upper edge of the bracket. Water is then poured into the glass until it flows out of the top of the metal tube *Q* into the basin. The measuring glass is then lowered slightly so that the water falls in *Q*. The relief valve from the breathing bag is then screwed over the end of the tube. Care should be taken that the valve seat is absolutely dry, as moisture may cause a false reading.

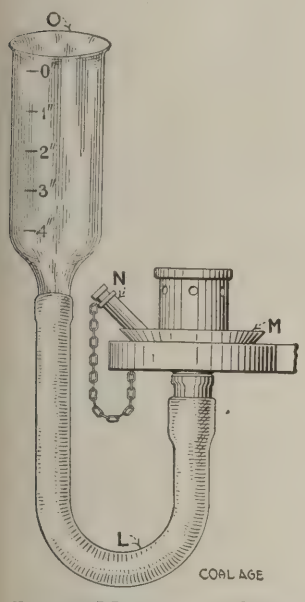

FIG. 4. MANNER OF TESTING PRESSURE AT WHICH RELIEF VALVE WORKS

The measuring glass is then slowly lifted until the water flows out of the hose in the upper part of the relief-valve casing. The pressure at which the valve releases will correspond with the number of inches the measuring glass is lifted. The water should begin to escape when the measuring glass has been raised about 1.2 in. (or about 3 cm.). The plug *N* can be pulled out and the water will thereupon run back into the measuring glass *O*.

This apparatus is made by the Maschinen-Fabrik Westfalia, at Gelsenkirchen, Westphalia, and is sold by S. F. Hayward & Co., 39 Park Place, N. Y. The device is suited to the testing of all forms of apparatus, except that the relief-valve meter is specially adapted to the proving of Westfalia apparatus, though it could be slightly modified so as to make it suitable for relief valves of other patterns.

Mine Regulations to Reduce Liability to Explosions

The following points in respect to reducing to a minimum the liability to mine explosions are sent by a mine foreman of long experience.

VENTILATION

1. Have exhaust system of ventilation.
2. Use explosion doors on fan.
3. Current must be neither too strong nor too weak.
4. Use 4- to 6-entry system, work in panels, keep air courses clear of obstruction.
5. Use overcasts instead of doors; if doors, use automatic.
6. Have stoppings substantially built of masonry and kept in good repair, check doors at necessary intervals so that ventilation reaches the face of workings.
7. Use separate splits freely, have all abandoned workings thoroughly ventilated.
8. Have ample ventilation exceed the requirements of the law if necessary.
9. Install duplicate fans and engines so that they can both be used together if necessary.
10. In all narrow work crosscuts should be driven at least every 100 ft., if driven every 200 ft., the limit, and canvas is blown down it will accumulate a dangerous body of gas.

SHOT FIRING

1. Employ skilled shotfirers acquainted with the extreme danger of gas and dust.
2. Use permissible explosives, copper bar and needle and clay tamping, fire one hole at a time with a battery when all men are out of the mine, commencing to fire shots, advancing against the air.
3. Do not shoot off the solid or holes drilled beyond the undercutting, shoot center hole first. If coal is 5½ ft. high and place 10 ft. wide shear one side or shoot in two layers.
4. Do not overcharge shots or use mixed explosives.
5. Holes must not exceed two inches in diameter.
6. Carefully inspect places for gas before shooting and after for fire, bad roof and gas.
7. Wet sides, roof and bottom for 80 ft. back before shooting.

DUST

1. Use sprays to wet the coal in the cars and spray empty cars outside or at the shaft bottom.
2. Keep rooms and haulage ways clear of dust by loading it out, keep coal below beds of cars.
3. Use water or exhaust steam for moistening dust.
4. Before shooting, wet sides, roof and bottom for distance of 80 ft.
5. Use tight wood or steel cars to prevent leakage of coal and clean it up regularly before it is ground into powder.
6. Dust is dangerous, because when acted upon by a flame, it generates carbon monoxide, it absorbs oxygen out of the air.

GAS

1. Do not allow mixed lights in a mine generating explosive gas.
2. Examine all places regularly and thoroughly for gas.
3. Do not allow accumulation of gas in worked-out portions of mine.
4. Consult the barometer for changes in the weather.
5. Employ competent and trustworthy firebosses and assistants.
6. Drawing stumps and pillars, take the coal out clean so roof can cave.

MISCELLANEOUS

1. Have good discipline in the mine.
2. Systematic timbering of working places to suit conditions.
3. Mine foremen, assistant mine foremen and firebosses must all be sober, competent and respected men and see that they observe fully the requirements of the mining law.
4. Have danger signals printed in all languages spoken at the mine.
5. Have accurate surveys made of the worked-out or abandoned sections of mine.
6. Instruct all classes in the danger of mining.
7. At least instruct all company men in First Aid and use of helmets.
8. Prohibit electricity in a gaseous mine and carefully guard its use in a nongaseous mine.

9. Use stone dust to deaden coal dust explosibility.

10. Work all rooms on retreating system.

11. Prohibit the breaking of large pieces of rock by laying dynamite on top of it, do not allow shots to be fired in air courses, headings and traveling ways unless wires are properly guarded, men warned and dust wetted.

12. In gaseous mines work rooms from one side only.

13. Shear and undercut coal properly before shooting.

Mine-Telephone Apparatus

The application of telephone systems to the mining industry is a comparatively recent one, but notwithstanding this fact the mine telephone has been highly developed. The requirements for constant and dependable service under all operating circumstances are exceptionally severe, in fact, it is safe to say they are unequaled by any conditions met with elsewhere in telephone operation. A brief review of these conditions and the manner in which they have been overcome in the design of modern mine-telephone equipment will be of interest to both the engineer and layman.

In general the greatest hazards to which telephone instruments employed underground are subjected are mechanical injury and the corrosive effects of acid mine waters and gases. Some of the mechanical sources of injury are falling roof materials, the concussion of blasting and rough handling by careless workmen. All these must be guarded against with a large factor of safety and each part must be given special treatment so that it will faithfully perform its functions.

A representative type of mine telephone as built by the Stromberg-Carlson Telephone Mfg. Co., is shown by Fig. 1. In this particular type of instrument, all of the apparatus is contained within a cast-iron box which has walls of ample thickness reinforced at the edges and corners to give adequate protection against injury. The operating parts are mounted inside an inner compartment, sealed by a door which is provided with a wide felt gasket. This compartment need not be opened except about once a year to replace the dry cells. As an additional safeguard against the entrance of air and moisture when the set is not in use, the outer door is fitted with a tubular rubber gasket which is compressed under the action of the door-lever mechanism.

The dome-shaped casting on top of the box shelters the gongs, gong mountings and armature assembly. The gongs are 4 in. in diameter so as to give a loud, clear signal and are triple zinc plated to render them corrosion proof. In mounting the ringers, so that no opening is made in the roof of the inner compartment, a unique scheme has been employed. By referring to the illustration, it will be noted that the ringer coils are inside the case with their magnet cores brought up through a brass plate.

As the clapper rod is mounted in a manner just the reverse of the usual arrangement it will be seen that there is no opening which might admit moisture. All of the ringer adjustment is made on one screw which is accessible by removing the dome.

Another feature which goes to show the importance of air-tightness is the manner in which the generator crank is brought through the inner door. The generator is equipped with a detachable coupling which separates when the inner door is opened. The section of the shaft which goes through the door itself is packed by means of a stuffing-box.

The equipment of these instruments includes the same operating elements as a regular magneto instrument, but the parts are in themselves especially designed for underground service and are consequently built heavier. The transmitter is of the long-distance type made up so as to be water-tight. The receiver is of standard form having a moisture-proof cord.

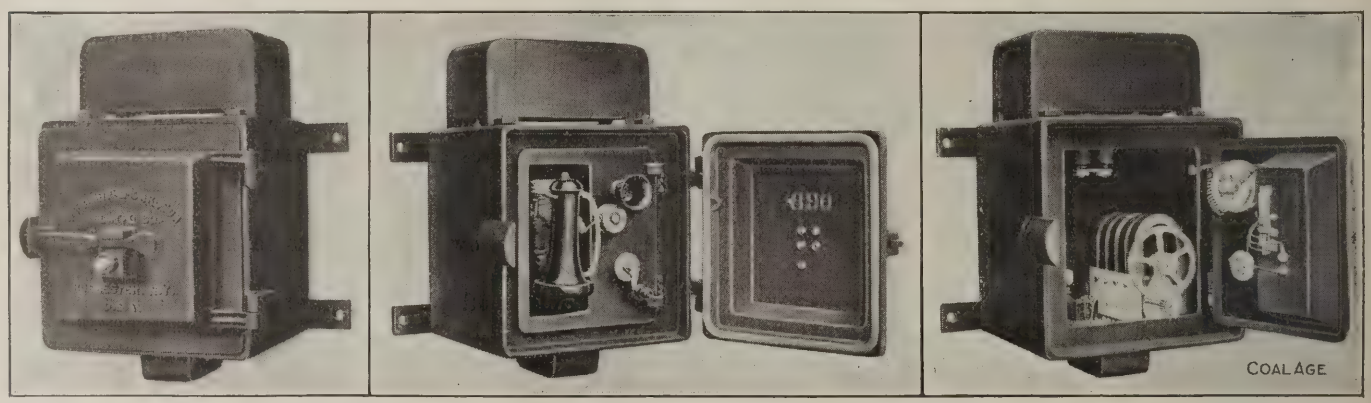

FIG. 1. THREE VIEWS OF A TYPICAL MINE TELEPHONE

A take-up device which is plainly shown in Fig. 1 draws the cord away from the door when not in use so that it will not be cut when the door is closed. A five-bar hand generator furnishes alternating current for ringing while the energy for talking purposes is drawn from two dry cells. The hook switch is not operated by gravity under the weight of the receiver but is actuated by wedging the receiver between the double jaws of the hook.

In general, all parts in the magnetic circuit of the set are made of iron which is given a zinc or copper plating. All other parts, including the screws, are of brass. Each coil is impregnated with a solid compound which successfully resists the action of mine gases and liquids and it is said that such mine telephones can be entirely submerged without injury to the apparatus.

The Nanticoke District Mining Institute, Nanticoke, Penn., will hold its fourth annual dinner at the State Armory, Saturday evening, Oct. 10 ,1914, at 7 o'clock. D. L. Morgan is secretary.

American Mine Safety Association

Special Correspondence

SYNOPSIS—The attempt of the American Mine Safety Association to hold a business meeting in New York City was a complete failure, but the meet at Terre Haute was an entire success and served to initiate an important safety movement through the State of Indiana. Teams attended from Pennsylvania and Illinois.

It is always difficult to forecast what will be the effect of a change in the method of conducting the business of a society and this was made distressingly evident in the recent attempted meeting of the American Mine Safety Association in New York City. Unfortunately the business session has always been too strictly business-like. There has been little deliberation regarding first-aid methods, almost none about mine rescue, and safety has been forgotten. Nearly all the discussion has been about organization and the most exciting part of the proceedings has been as to the person who should be presiding officer and to the time of paying dues.

Whenever anyone has suggested discussing first-aid methods, someone has objected to submitting matters of that kind to a mixed body of doctors and laymen, and there the matter rested. As none of the meetings really "tended to edification," if we may quote the evangelical formula, there has been a growing dissatisfaction with the business meeting, though the feeling had little to do with the real progress of the association.

No Discussion of Principles but Much Commendable Activity

In brief, the society has been short on dogma and quite long on practice. The first, as exemplified at the New York City session, was a failure, the second, as portrayed at Terre Haute, Ind., was, as usual, a success. When the meets were held in the same place as the business meeting, they served to help out the latter and give it a semblance of life which intrinsically it did not have.

But dogma is useful. We feel that first aid, and, in a lesser degree, mine rescue, also has need of much of it and safety has a literature which has not at all been extended by the society which calls itself a Mine Safety Association.

We need to discuss and define how first-aid work should be done, perhaps also we need to prescribe just how it shall be performed at contests. The teams are often demerited for doing "what the doctor ordered," and one judge will approve what another will condemn. Such a conflict is common in all branches of art and industry, but it is folly to subject men to a loss of credit because they have done something which they have been taught to do and performed some act which no definite regulations forbid.

If there is going to be criticism of "doctor's orders," we think it will show itself most forcibly where no method is prescribed by authority and if every doctor who acts as a judge is permitted to use his own judgment. The clashes of authority will be felt most severely if those who suffer from the conflict are those who can have no hand in the settlement. If the doctors proverbially differ, it is not well to make the first-aid men they train get the burden of the disagreement by demerits in the judgment of contests.

Why Not Some Interesting Papers?

Sometimes we wonder whether a few papers read before the association would not serve a good purpose. We are convinced that there are too many papers presented already at public gatherings, that many had better have never been penned and most had far better been penned than delivered, but if papers could be volunteered or the right man asked to deliver them, it seems that interest would be added to the meetings, and perhaps also, as the association appears to have forgotten it, it might be well to call the attention of the members to the fact that it is true of the association that "safety is its middle name." A few addresses on methods of making the mine safe would surely not come amiss.

The meeting met on Sept. 7, Labor Day, at the Waldorf-Astoria, the president and secretary and about a dozen others being present. The next day fifteen first-aid and

Vandalia Coal Co. Team No. 20, Linton, Ind.

rescue men of the Lehigh Valley Coal Co. made an excellent exhibition in the Waldorf-Astoria, at which about as many members as exhibitors were present.

The Lehigh Valley Coal Co. generously sent the Westmoreland team and the captains of the best teams in each of the five divisions in charge of Efficiency Engineer John Lloyd, and kept them in New York City three days, giving them a good opportunity to see and enjoy the town and paying their way to places of entertainment. The appreciation of the company for the good work of its men has made them most enthusiastic adherents of the safety movement.

On the 9th, the Delaware, Lackawanna & Western R.R. coal department sent a first-aid and mine-rescue team from the Central Mines, with the superintendent, T. J. Williams, and the rescue foreman, John A. Thomas, in charge. Owing to the fact that the meeting was called to an early close, this corps brought no equipment, but spent two days in New York City visiting places of interest.

Business Meeting at Terre Haute, Ind.

In the afternoon of Sept. 11, the executive board of the American Mine Safety Association met in the rooms of Terre Haute House, Terre Haute, Ind. The annual meet-

THE LINE-UP OF TEAMS AND OFFICIALS AT THE MEET OF THE

ing was held in the evening at the Chamber of Commerce with John P. Reese presiding. The principal officers elected for the succeeding year were President Dr. August F. Knoefel, chief surgeon, Vandalia Coal Co., Terre Haute, Ind.; First Vice-President, Joseph Fletcher, Cherokee-Pittsburg Coal & Mining Co.; Second Vice-President, F. W. Sperr, professor of civil and mining engineering, Michigan College of Mines, Houghton, Mich.; Third Vice-President, William Green, Secretary-Treasurer United Mine Workers of America, Indianapolis, Ind.

The other members of the executive committee are as follows: W. H. Aldrich, managing director, Inspiration Consolidated Copper Co., 14 Wall St., New York City; Dr. Ralph McHenry, chief surgeon, Penn-Mary Coal Co., Heilwood, Penn., and Albert Burch, general manager, Goldfield Consolidated Mines Co., Goldfield, Nev.

REPORT OF SECRETARY SHOWS PROGRESS

The business meeting opened with a report by Secretary-Treasurer H. M. Wilson. It showed that on Sept. 1, the membership of the association was 549 and represented practically every part of the American continent. The association has awarded 101 medals since October, 1913, comprising 5 bronze mine-rescue medals, 10 silver first-aid medals and 86 bronze first-aid medals.

It was decided to appoint an organizer, who will devote his time to increasing the membership and whose salary will be a certain percentage of the dues. The members concluded to hold the next annual meeting at Philadelphia, Penn. A medal was voted to John C. Davidson, now an employee of the J. Wooley Coal Co., of Evansville, Ind. Mr. Davidson risked his life to save others at Starkville, Colo., Aug. 10, 1910, and again at Dawson, N. M., at an explosion which occurred Oct. 22, 1913.

J. W. Paul, engineer in charge rescue department, Bureau of Mines, Dr. R. F. McHenry, chief surgeon, Penn-Mary Mines, and A. M. Ogle, president and general manager, Vandalia Coal Co., Terre Haute, Ind., were appointed on the general auditing committee. Dr. August F. Knoefel and Prof. E. W. Sperr were appointed a committee to audit the books of the secretary-treasurer. Dr. Knoefel, retiring chairman of the first-aid committee, recommended the adoption of the Shaeffer method of respiration in place of the Slyvester, and the recommendation was adopted. After much discussion, it was decided to give special medals to the "subjects" of all teams to which first-aid medals are awarded.

JOHN C. DAVIDSON, WHO RECEIVED MEDAL FOR REAL RESCUE WORK

EVENTS ARE PREANNOUNCED

At 10 a.m., on Sept. 12, the field contests began in the Central League Baseball Park. Music was furnished by the American Federation of Musicians' Band, from Local No. 25.

The events had all been published before the contest. It is quite customary to publish the list from which the judges choose and this was done in this particular case, but strange to say, the events of the contest chosen for performance were all set forth at length in the morning papers before the meet commenced, so everyone had warning of what to expect.

LIST OF THE COMPETING FIRST-AID TEAMS

The teams competing were as follows:

Indian Creek Coal Co., Bicknell, Ind.; J. K. Dering Coal Co., Clinton, Ind.; Bunsen Coal Co., Westville, Ind.; Bunsen Coal Co., Universal, Ind.; Superior Coal Co., Gillespie, Ill.; Penn-Mary Coal Co., Heilwood, Penn.; O'Gara Coal Co., Harrisburg, Ill.; Vandalia Coal Co. No. 82, Terre Haute, Ind.; Consolidated Indiana Coal Co., Sullivan, Ind.; Knox Coal & Mining Co., Bicknell, Ind.; J. Wooley Coal Co. No. 2, Paxton, Ind.; J. Wooley Coal Co. No .1, Paxton, Ind.; Western Indiana Mining Co., West Terre Haute, Ind.; Lower Vein Coal Co., Terre Haute, Ind.; Green Valley Coal Co., Jasonville, Ind.; Sugar Camp Coal Co., West Terre Haute, Ind.; Vandalia Coal Co. No. 69, Terre Haute, Ind.; Vandalia Coal Co. No. 10, No. 1 team, Dugger, Ind.; Vandalia Coal Co., No. 20, Linton, Ind. (two teams); Vandalia Coal Co. No. 10, Dugger, Ind.; Monon Coal Co., Sullivan, Ind.; Vandalia Coal Co. No. 9, Linton, Ind.; Clinton Coal Co., Clinton, Ind.; Cambria Steel Co., Johnstown, Penn.; Superior Coal Co. No. 3, Gillespie, Ill.; Superior Coal Co. No. 2, Gillespie, Ill.; Calora Coal Co., Jasonville, Ind.; O'Gara Coal Co., Harrisburg, Ill.

The one-man event was: Treat a simple fracture of the right collar-bone and a simple fracture of the lower jaw. Time allowed, 20 min.

The two-man event required: Treat left leg lacerated by machine, flesh torn loose and bone exposed. Time allowed, 10 min.

American Mine Safety Association, Terre Haute, Sept. 12, 1914

In the three-man event, the left ear of the patient was supposed to be torn off, the left shoulder dislocated and the left leg had a compound fracture. The time allowed was 25 min.

Unnecessary Torture to Patients and Subjects

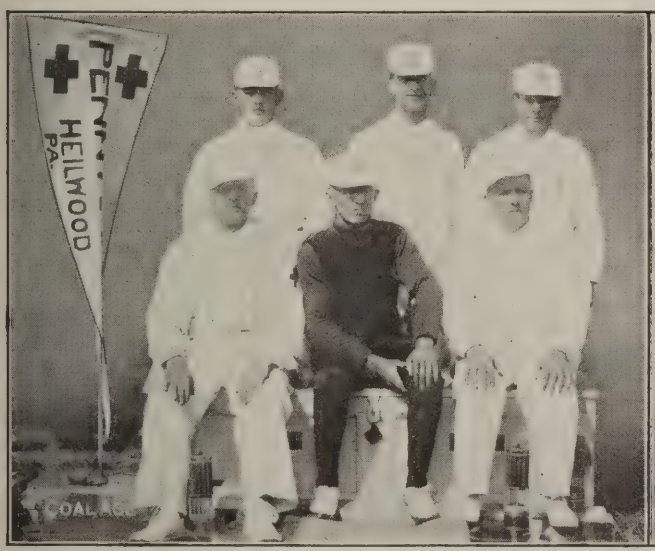
There were, as before, many who put the torniquet on the thigh instead of at the knee, which is not the right place. They also tightened it. The pressure on the artery may be necessary or it may not. It is best to put the torniquet in place so that it can be tightened at any time. It is true that bleeding may occur and the first-aid man should be always prepared for it, but it is a mistake to say that a compound fracture always involves hemorrhage. It rarely does, according to the statement of physicians of experience, and the torniquet should be tightened only when necessary.

Consequently, first-aid men should learn to leave that instrument of torture loose if for no other reason than that the subject is apt to suffer no little pain if the judges are slow and the pressure severe. It is important to make the contestants realize that a torniquet is tightened not to *guard* against the possibility of bleeding, arterial or capillary, but only to prevent severe hemorrhage when it actually occurs. A loose torniquet should score always a better mark than a tight one.

The four-man event consisted of the resuscitation of a patient found unconscious from gas inhalation, with right forearm broken. A stretcher was improvised and the patient was carried 50 ft. The time allowed was 25 min.

Did Not Know if Man Was Drowned or Suffocated

It is perhaps permissible to call attention to the fact that some of the teams treated their subjects as if the misfortune which had come to them was that of drowning. Not by any manner of means can lifting a man up and lowering him down by a grasp of his waist be said to be performing the Shaeffer treatment. There is, of course, some value in such a method of procedure; some tidal air enters and leaves the lungs, but there is not nearly the pulsating effect produced by pressure at the right point.



The first full-team event illustrated the treatment of a man found lying on a live electric wire, unconscious, with back burned at the waist line. Three methods of removal were to be portrayed and the man was to be treated and carried on a stretcher 50 ft. The time allowed was 30 min.

The Penn-Mary Treatment of a Broken Back

The crowning exhibition was the treatment of a broken back by the full team. Time allowed, 25 min. The Penn-Mary team performed this feat as at the Pitsburgh meeting and the work excited general interest. But, altogether aside from the merit of the work from an anatomical point of view, and apart from the ingenuity of the dressing and the perfection of the bandaging, the action of the team was admirable from start to finish.

A little roughness with a man with a broken leg or a scarified arm may do but little harm. In fact, the chance to be rough and careless is not so manifest. But in preparing to bring a man out who has broken his back, there is every chance to be rough and clumsy without intention, and there is the greatest of danger to the patient if that awkwardness is manifested, and here again does first-aid become essential.

For this is essentially a full-team event. No physician could turn the trick alone. He is obliged to have a number of assistants, and we are confident he could not train them in the few minutes prior to the transference of the

First-Aid Team of the Penn-Mary Coal Co., Heilwood, Penn.

One of the First-Aid Teams of the Cambria Steel Co., Johnstown, Penn.

patient from the ground or the car to the splints. Only by taking his nurses into the mine could he give the patient that tender, considerate care which the first-aid men exhibit. The deftness of the Penn-Mary men was remarkable. There was a remarkable coördination of movement, the like of which one rarely sees.

When, however, 3F black blasting powder of equal deflective force, tamped with 2 lb. of dry fireclay, was used instead of the aforementioned explosive, the explosion was violent. It was evident that the coal dust which was again placed after the first experiment, took part in the action. Flame burst from the mouth of the gallery and

TWO SCENES IN MINE-RESCUE CONTEST

Rescuing a victim — Crossing over an overcast

Several illustrations are shown of the patient being dressed. It will be noted that it is anticipated that he will be found face down, whereas the general supposition as staged is that he will be discovered lying on his back—a most unlikely condition. The idea of the Penn-Mary dressing is to put the weight of the legs and arms on the splints and to carry these parts a pick is placed between the legs, other picks are placed in the arm pits and they are all deftly and securely attached to the splints.

THE GALLERY DEMONSTRATION

Not a little interest was shown in the steel gallery, which had been erected to show the dangers inherent in the use of black powder. In few places is the need of such a demonstration of the value of short-flame explosives more evident than in the State of Indiana. In the mines of that state, shotfirers are engaged, coal being largely shot from the solid and black powder seems universal. Thus the dangers of coal dust cannot be too strongly emphasized.

As at other meets, a shot of permissible explosive, having a deflective force of one ½ lb. of 40 per cent. straight nitroglycerin dynamite, was tamped with 1 lb. of dry fireclay. This was fired from a cannon in the end of a long gallery in the presence of bituminous-coal dust 100-mesh fine. The explosion resulting was not severe and was evidently due to the powder only and entirely unaided by the ignition of the coal dust.

THE COAL-DUST EXPLOSION RESULTING FROM THE USE OF BLACK BLASTING POWDER

was followed for a long time by a heavy smoke, which also poured from the safety valves along the top. The picture gives a vivid representation of the large quantities of smoke formed and no one could doubt that the coal dust had done its part in producing the loud detonation, the livid flames and the great clouds of smoke, so unlike that formed by powder.

MINE-RESCUE WORK

Meantime the first-aid teams were working off their ties and the mine-rescue teams were being examined and put through their drill. Rescue teams are numerous in Indiana. The full list of the competing teams will prove that; there were 11 in all of these, yet only one came from outside the state.

The list follows: Superior Coal Co., Gillespie, Ill.; Vandalia Coal Co. No. 82, Terre Haute, Ind.; Knox Coal & Mining Co., Bicknell, Ind.; J. Wooley Coal Co., Paxton, Ind. (two teams); Bunsen Coal Co., Brazil, Ind.; Clinton Coal Co., Crown Hill team, Clinton, Ind.; Vandalia Coal Co. No. 69, Terre Haute, Ind.; Vandalia Coal Co. No. 20, Linton, Ind.; Vandalia Coal Co. No. 9, Linton, Ind., and Vandalia Coal Co. No. 10, Dugger, Ind.

THE SMOKER AND AWARD OF PRIZES

In the evening, a smoker was held in the banquet hall of the Terre Haute House, at which all the teams and guests were present. H. M. Wilson was toastmaster. The speakers consisted of Donn M. Roberts, the Mayor of Terre Haute, who delivered the address of welcome; John P. Reese, the past president of the association; William Houston, president of United Mine Workers Union, No. 11; Edgar A. Perkins, chief of the Indiana mine inspectors' bureau; Carl Sholz, president of the American Mining Congress, and Dr. A. F. Knoefel, the incoming president. William Houston declared that the union should back safety and first-aid work with the utmost vigor and declared that he believed that the existence of unions promoted safety.

Dr. Knoefel presented the prizes. The list is extremely lengthy and must necessarily be abbreviated. The special resuscitation prize, a silver cup donated by S. F. Hayward & Co., was presented to the Penn-Mary Coal Co., of Heilwood, Penn., for the second time, and now becomes their permanent property.

The team consists of J. Fleming, captain; T. E. Engle, subject; Harry Davis, John Stone, Gottlieb Stone and William Stout.

The team scoring the highest general average was that of the Bunsen Coal Co., Westville, Ill. The names of the members of the team are: John Krainok, captain; C. Newman, subject; J. De Barker, Steve Shaffer, Charles Elliott and

places in the order named: Vandalia Coal Co., Mine No. 10, No. 1 team; O'Gara Coal Co., Harrisburg, Ill.; Monon Coal Co., Cana, Ind.; Vandalia Coal Co. No. 20, Linton, Ind.; Indian Creek Coal & Mining Co., Bicknell, Ind.; Sugar Valley Coal Co., West Terre Haute, Ind., and Knox Coal & Mining Co., Bicknell, Ind. The prizes awarded were of a miscellaneous character, including Hirsch and Wico electric safety lamps,

PENN-MARY TEAM OPERATING ON MAN WITH BROKEN BACK

Transferring patient onto long splints

Securing picks between the legs and under armpits

Stull Boots. As a reward, they received $100 donated by the Indiana Coal Operators' Reciprocal Organization, Terre Haute, Ind. Also, the Colliery Engineer Challenge Cup, which now passes from the Penn-Mary Coal Co. team, which held it last year. Each member of the team received American Red Cross bronze medals and American Mine Safety Association silver medals.

The Penn-Mary Coal Co., of Heilwood, Penn., received second place and were presented with a Burroughs-Welcome Tabloid First-Aid Case, American Mine Safety Association bronze medals and American Red Cross certificates.

The team of the J. K. Dering Coal Co., Oak Hill mine, Clinton, Ind., secured third place, receiving American Red Cross certificates and medals donated by the Indiana Operators' Reciprocal Organization.

The following teams secured fourth, fifth, sixth, seventh, eighth, ninth, 10th, 11th, 12th and 13th places, respectively, and received medals donated by the Indiana Coal Operators: Vandalia Coal Co., No. 9 mine, Linton, Ind.; Clinton Coal Co., Clinton, Ind.; Superior Coal Co. No. 2, Gillespie, Ill.; Superior Coal Co. No. 1, Gillespie, Ill.; Calora Coal Co., Jasonville, Ind.; Superior Coal Co. No. 3, Gillespie, Ill.; Vandalia Coal Co., No. 82 mine, Terre Haute, Ind.; Cambria Steel Co., Johnstown, Penn.; Bunsen Coal Co., Universal, Ind., and J. Wooley Coal Co. No. 1, Paxton, Ind.

Prizes were also given to the following, who obtained an electric coffee percolator, a Johnson & Johnson first-aid cabinet, a carafe and several bottles of liquid soap.

PRIZE FOR EFFICIENCY IN IMPROVISING DRESSINGS

The Calora Coal Co., of Jasonville, Ind., received a special prize for proficiency in improvising material and dressings. Each of the teams received a Baldwin acetylene lamp. The team scoring the highest number of points in the one-man event was that of the O'Gara Coal Co., No .1 mine, Harrisburg, Ill. The team received a Westinghouse electric fan and two bicycle tires.

The Penn-Mary Coal Co., Heilwood, Penn., received subscriptions to some engineering papers in recognition of its supremacy in the two-man event.

The Colliery Engineer Challenge Cup was won by the mine-rescue team of the J. K. Dering Coal Co., of Clinton, Ind. The members of the team are: Scott Amour, captain; Matthew Kerr, George Waters, George Wilson and Stanley Howell. The other contestants scored as follows: (2) J. Wooley Coal Co. No. 1, Paxton, Ind.; (3) J. Wooley Coal Co. No. 3, Paxton, Ind.; (4) Superior Coal Co., Gillespie, Ill.; (5) Bunsen Coal Co., Universal, Ind.; (6) Vandalia Coal Co., Terre Haute, Ind. The winners of second place received medals from the Indiana Coal Operators, a Koehler aluminum safety lamp, an American safety lamp and other prizes.

The smoker was followed by a vaudeville performance and some moving pictures, including a presentation of the first safety meeting in 1911 and some scenes in the interior of the United States Coal & Coke Co.'s mines in Gary, W. Va.

THE PENN-MARY AND MONON COAL COS.' DRESSINGS FOR BROKEN BACK

The recorders for the first-aid contests were D. M. Duncan and T. S. Martin, both of Terre Haute and E. C. Lee, Harrisburg, Ill. The recorders of the mine-rescue events were E. C. Lee, J. T. More, Denver, Colo., and A. I. Young, Pittsburgh, Penn. Among the judges was Dr. Tuthill of the Copper Queen Consolidated of Morenci, Ariz.

On Monday, Sept. 14, there was a practical exercise for all the mine-rescue teams at the mine of the Glen Ayr Coal Co. This mine had been closed for some time and was full of blackdamp. As a result of the helmet work and other care taken, no one was affected by the operations in the mine except Dr. A. F. Knoefel, who was nearly drowned in the sump.

The Susquehanna Meet

SYNOPSIS—At the Susquehanna meet all the contestants solved the same problems. The awards were not based on average efficiency, but prizes were given for the first and second-best team in each event. A safety exhibit and a breaker boys' team were important new features.

This year the Susquehanna and Lytle Coal Cos. have 44 teams enrolled as against 42 a year ago, and the enthusiasm for first-aid work has increased rather than diminished. In making his speech Morris Williams, the president, referred with pleasure to this growing interest, which was really not expected by anyone. A few years ago everyone predicted that the interest was one which would pass like a fad.

But, as a matter of fact, the study of first-aid is continually growing, not only in new places, but at its point of origin in the United States—the anthracite region. The study is expected to invade the schools shortly, and the children will enter the mines endoctrinated with safety notions and prepared to render first-aid. Then the whole attitude of the mining population will change for the better. In fact, as Mr. Williams declared, to doubt that the movement will grow and spread is to question the humanitarianism of the miners and operators, and is not creditable to those who indulge in such pessimism.

The contest, which was held on Saturday, Sept. 26, was the fifth of the series It was held as before at Edgewood Park near Shamokin, Penn., special trains being run to carry the men to that point. The judges were Dr. J. B. Rogers, of Pottsville, Dr. D. H. Lake, of Kingston and Dr. James W. Geist, of Wilkes-Barre. The surgeons of the company were in charge, but they had nothing to do with the judging. They are Drs. J. M. Maurer, G. M Stites, B. C. Guldin and J. H. Hughes.

It may be pointed out that all the three judges examined the work in every event when completed. Each made a separate estimation of the award due to each team, and the averages of these were credited to the various teams. In this way, the utmost care was taken to evaluate the character of the completed work.

Safety Exhibit at the Susquehanna Meet

Breaker Boys in Two-Man Event

Improvement in Work Manifest

Perhaps this method does not invite such a scrupulous attention to the care of the patient. The end is apt to be kept in view rather than the means. But it is said that the training of the last year has improved the men immensely in this particular, and the litter work showed a great improvement. Some teams, however—a few only be it noted—carried their litters nonchalantly, and a box of tools would have been better carried by such bearers than an injured man. For the most part, however, the first-aid men broke step and walked slowly, and the rhythmic movement of the springs was not in general visible to the eye of a spectator in the grandstand. The bandaging appeared more than usually good.

Breaker-Boy Team

Spread under the Trees

THE EVENTS IN DETAIL

The first event for one man only was as follows: Sprain of left ankle. Make a one-man rescue and carry to station (wrist carry). Dress with short splints. Time, 6 min.

The first prize in this event went to No. 1 and No. 5 slopes of the Pennsylvania Colliery, Mt. Carmel. The teams comprised the following: William Matthews, captain, motorman; Robert Kendtner, pumpman; Andrew Saduskie, footman; Andrew Zigray, footman; Felix Fifer, driver, and Albert Evans, subject, motor conductor. The second prize went to the team of No. 6 tunnel, Colliery No. 6, Glen Lyon.

The second event was for two men only and ran as follows: "Man found unconscious on road with right hand in contact with electric wire. Rescue, revive with artificial respiration by Sylvester method. Dress burn on hand. Carry 10 ft. with four-handed seat."

The first prize in this event was also secured by the efficient team from No. 1 and No. 5 slopes of the Pennsylvania Colliery, Mt. Carmel, Penn. The second prize fell to No. 4 slope of Colliery No. 5, Nanticoke, Penn.

The third event was for three men. The patient had a simple fracture of the right knee cap, a lacerated wound of the left shin bone and a fracture of the fifth and sixth ribs on the right side. The bandaging of the team of No. 2 shaft of Colliery No. 5, Nanticoke, Penn., was awarded the first prize. The team consists of the following members: Ernest Bleith, captain, shoer; John Wadzinski, timekeeper; David Edwards, driver-boss; Frank Riefski, head runner; Arthur Gething, timekeeper, and Michael Weiss, subject, runner. The next best team was that of the outside men of Richards Colliery, Mt. Carmel, Penn.

The full team event required the bandaging of a broken jawbone, of a fracture of the left collar bone and of a compound fracture of the right arm and a fracture of the pelvis.

The winners of this, the principal event, were the No. 1 team of Williamstown. The men comprising that team are as follows: Joseph Llewellyn, captain, footman; James Byerly, breaker boss; William Smith, fireboss; H. Troutman, machinist; John Gittings, inside timekeeper, and Felix Samuels, subject, breaker clerk.

The second prize for the full-team event was awarded to the Richards Colliery, outside team, Mt. Carmel, Penn. As they also secured a second prize and distinguished themselves in this, the main event, we give their names: D. P. Burke, captain, breaker machinist; Jacob Hollister, fireboss; Charles Dietz, carpenter; Ralph Bickel, blacksmith helper; Herold Brokenshire, timberman, and George O'Donnell, subject, machinist helper.

The winners in the first three events received French bronze medals while those who won in the full-team event obtaining first prize were awarded a silver cup and medals of gold bronze. A silver medal was given, in recognition of his able directorship, to Dr. G. M. Stites, who trained the team.

The prizes were handed to the winners by nurses from the State Hospital at Shamokin. They were interested spectators of the events throughout the day. Reference is made in our editorial columns this week to the speeches delivered after the presentation of prizes.

AN EXHIBIT OF SAFETY METHODS

The exhibition of safety methods at the gate was extremely interesting and attracted much attention. It is a pleasing addition to first-aid meets, for however desirable first-aid may be, safety always stands one notch higher, as prevention is always better than cure. It is perhaps not so easy to exhibit these strivings for safety as it is to demonstrate first-aid work, but whatever can be done should be attempted. The pay statements which were exhibited with safety maxims printed across their faces are valuable aids to safety, especially seeing that the Susquehanna Coal Co. changes these maxims on the occasion of every pay, so that new admonitions are continually presented.

The Meet of the Philadelphia & Reading Coal & Iron Co.

SYNOPSIS—The methods of conducting the Reading meet are different from those pursued by most other companies. Their roller-bandage work is marvelous and the labors of the first-aid corps together with certain preventive measures have reduced accidents markedly.

The Reading company meet is always regarded as one of the leading events in the anthracite region and the roller-bandage work done by the teams of the company is conceded to have no equal. One of the interesting features is that the teams of each district draw numbers in the elimination contest, and according to these drawings they are set to perform some one of a series of problems.

Those who perform these with due skill enter the final contest which is a single problem, announced beforehand, and the same for all teams. The work done in this final event is therefore merely a test of skill for it may be assumed at once that every team entering will have the necessary *knowledge* to enable it to earn 100 per cent. from the judges.

This year the winner was the team of the Draper Colliery. Everyone regarded the Wadesville dressing with

THE TEAMS WHICH, IN PROBLEM 2, TREATED THEIR PATIENTS FOR COMPOUND FRACTURE OF JAW AND LACERATION OF RIGHT EAR

much favor and perhaps it appealed also to the judges but doubtless the ruling on the program weighed in the result and the Wadesville team had violated it. This admonition runs: "The dressing of all injuries is to be done with material issued for the purpose."

The Problems Presented

The meet was held at Lakeside Park, East Mahanoy Junction as usual and on Saturday, Sept. 19. The corps of each district drew one of the following 10 problems:

1. Handling by one, two and three and litter. Cross-obstruction and load ambulance. Time allowance, 12 min.
2. Compound fracture of jaw. Laceration of right ear. Two 2-in. bandages. Time allowance, 5 min.
3. Compound fracture of right forearm. Simple fracture of left forearm. (Dress arms at same time.) Five 2½-in. bandages; one torniquet; three pieces of gauze; two triangular bandages. Time allowance, 10 min.
4. Dislocation of knee. Laceration of thigh with severe hemorrhage. (Opposite sides.) Six 2½-in. bandages; two gauze compresses; one torniquet. Time allowance, 6 min.
5. Artificial respiration, Shaffer and Sylvester methods. Use of oxygen trunk, inhalator and pulmotor. Time allowance, 10 min.
6. Burns. Left forearm, arm, head and face. Four 2½-in. bandages; six gauze squares. Time allowance, 8 min.
7. Dislocation of elbow, with laceration of fingers. Four 18-in. splints; four pieces of gauze; four 1-in. bandages; two 2½-in. bandages; two triangular bandages; one torniquet. (Dress both injuries at same time.) Time allowance, 15 min.
8. Rescue from electrical contact. Patient unconscious. Examine for injuries. (Dress one injury.) One 2½-in. bandage; one piece of gauze. Time allowance, 6 min.
9. Heat exhaustion. Falls, fractures skull. Resuscitate and dress fracture. Two gauze bandages; one piece of gauze. Time allowance, 6 min.

These Teams Demonstrated How to Treat a Man Exhausted by Heat, Who Has Fallen and Broken His Skull

View of the Field in the Final. Bandaging Foot, Knee, Leg, Thigh and Hip

Winning Team from Draper Colliery and Bandage Awarded First Prize

10. Fracture of spinal column, and dislocation of shoulder. Nine 4-in. bandages; two 3-in. splints; one blanket. Time allowance, 6 min.

After the contest it was ascertained the scores were as follows: Tunnel Ridge, 97 per cent.; Turkey Run, No. 1, Inside, 96 per cent.; Potts, Inside, Primrose Slope, 96 per cent.; Lincoln, 95½ per cent.; Maple Hill, Inside, 95 per cent.; Draper, Outside, 95 per cent.; Otto, 95 per cent.; Alaska, 94 per cent.; Wadesville, 93 per cent. and Bear Valley, Inside, 93 per cent.

The Excellent Deportment at First-Aid Meets

The company had sent to the field over night a train-load of colored waiters and cooks and a sumptuous repast had been prepared. It was creditable to the assembled crowd that the caterers had not hesitated to provide the best of equipment and their judgment was well founded. Such dishes as were used on the table would not have been furnished in any but the best of hotels. In fact, not only the Reading meet but all those in the anthracite region are marked by the excellent deportment of the participants. There are none of the unfortunate incidents which occasionally slightly mar the banquet sessions of some of our mining associations, where managers, foremen, engineers and salesmen constitute the personnel.

In the afternoon, the final problem was performed, with the result that Draper colliery received 98 per cent. So close was the decision that five additional physicians were called into consultation with Dr. T. C. Fegley, of Tremont, Penn., and Drs. A. J. Baur and L. M. Knauber, of Wilkes-Barre, Penn.

Improvement in Safety

The pennants and prize ribbons were presented by Miss Lorraine Richards, Miss Majorie Koch, Miss Hazel Quinlan, Miss Eleanor Powers, Miss Frances Mortimer and Miss Helen Richards. After the awards were announced, Judge Richard H. Koch, of Pottsville, congratulated the winners in a short speech and read a letter from James E. Roderick, the chief mine inspector to the president, W. J. Richards. Mr. Roderick stated that in the first six months of 1913, the accidents inside the Reading mines were 47 in number as against 21 in the same period in 1914. Outside the mines there were 11 accidents in the first half of 1913 and 4 in 1914. Thus the improvement was 55 per cent. underground and 64 per cent. on the surface or 57 per cent. as an average. Much of this improvement, the judge said, must be ascribed to first-aid work.

The importance of the meet can be judged from the fact that 77 teams comprising 503 men were entered in the contest. About 1600 people were on the field and three bands lightened the business-like character of the occasion. There was a small exhibition of mine-rescue work in a smoke room and in the test probably a half-dozen men took part. The Reading has 1740 men trained to wear mine-rescue helmets.

Next Annual Meeting of the American Mining Congress

The seventeenth annual session of the American Mining Congress will be held at Phoenix, Ariz., Dec. 7, 8, 9, 10 and 11, 1914.

The same plan will be followed as that of last year: namely, all the leading papers will be printed and distributed in advance of the convention. This plan gives better opportunity for direct discussion of the papers presented and facilitates reaching intelligent conclusions. The printed pages will be distributed to members and the author given ten minutes to make any desirable supplementary statement. Two or three speakers will be asked to make ten-minute addresses and then the discussion will be open to all delegates.

Among the subjects which will be discussed are the following: Western Mining Conditions, Mine Manufacturing, Mining Investments, Safety, Federal Aid in Mining, Federal Aid to Mining Schools, Water Power Development, Conservation, Workmen's Compensation, Development of Minerals in Reservations, Rights-of-Way on the Public Domain, Mine Taxation, Revision of Mining Laws and Compulsory Arbitration.

While the entertainment features will be so planned as not to interfere with the work of the convention, more time than usual will be allowed from the regular sessions. The local entertainment committee will be ready to make enjoyable every minute not occupied by the business of the Congress. President, Carl Scholz; Secretary, J. F. Callbreath.

The Muckle Cup Contest

SPECIAL CORRESPONDENCE

First-aid corps from 18 of the collieries in the Wyoming and Lackawanna Valleys gathered at Valley View Park, near Wilkes-Barre, on Saturday, Sept. 19, to compete for the Mrs. John S. Muckle cup. This contest is conducted annually under the auspices of the American Red Cross. About 1500 people from the stretch of coal territory lying between Mayfield on the north and Nanticoke on the south attended the meet.

Each year the intercompany meet is the cause of spirited rivalry but there is always evident that spirit of fairness and that desire on the part of all the contestants to see the best team win. This year's event was no exception to the rule, and while each team took the field with the determination of carrying off the coveted trophy there was no dissension when the judges had completed their work. The various companies which had teams in the meet declared a half holiday in order that every man might avail himself of the opportunity of witnessing the teams in their annual contests.

Owing to the fact that Major R. U. Patterson has gone to Europe to render services to the injured in the great war, Dr. M. J. Shields, field agent of the American Red Cross, is now in general charge of American Red Cross work and in that capacity conducted this meet. He declared that the contest was one of the best in the history of the competition for the Muckle cup.

Four problems were given each team and the percentages of the four events were averaged and the team with the highest average was declared the winner. The first-aid teams were so carefully trained and drilled, and showed such an expert knowledge of first-aid work, that after the last event was over it was discovered that the Central colliery team of the Delaware, Lackawanna & Western R. R. Co. Coal Department, and the Lackawanna colliery team of the Temple Coal Co. were tied with a perfect average, each team having scored 100 points in each of the four events. But further proof of the proficiency of each team came when the judges announced that the lowest average made by any team in the contest was 94.

The Old Forge team of the Pennsylvania Coal Co. carried off the cup last year but while it did excellent work in this contest, its general average of 95 made it tie for thirteenth place.

In order to decide the cup winners it was necessary for the Central colliery and the Lackawanna colliery teams to work out an extra problem. The judges carefully watched their work in the final contest and rigidly marked them, but these teams displayed such a wonderful knowledge of first-aid relief that the judges debated over their standing for some time and finally decided that the Lackawanna team was entitled to a mark of 99 for the extra event and the Central team was entitled to a credit of 98½. This made the Lackawanna team the cup winners and gave the Central team second honors in the contest. Besides having possession of the cup for one year, each member of the Lackawanna team was given a Red Cross medal. The events were as follows:

Event No. 1—For one man—Treat a lacerated wound of the forehead and a like wound of the right hand. Ten of the teams scored a perfect mark in this event.

Event No. 2—For two men—Left leg lacerated by machine bits, flesh torn loose and bone exposed but not fractured. Nine of the teams had a perfect score in this event.

Event No. 3—For four men—Fingers and left hand lacerated, bright red blood, compound fracture of right forearm. Eight teams had a perfect score in this event.

Event No. 4—For full team—Simple fracture of right thigh; fifth and sixth ribs on left side broken; compound fracture of right wrist with bright red bleeding. Five teams had perfect scores for this event.

Extra Event—For full teams of Lackawanna and Central

Taylor	D., L. & W.	94	96	93	94	94

Mrs. John S. Muckle is a resident of Philadelphia and the cup for which the teams competed was donated in 1909 and its holders have been as follows:

CENTRAL TEAM OF THE "LACKAWANNA" CO.

1909, Avoca team of Pennsylvania Coal Co.; 1910, Woodward colliery team, Delaware, Lackawanna & Western R.R. Coal Department; 1911, Brisbin team, Delaware, Lackawanna & Western R.R. Coal Department; 1912, Pine Brook colliery, Scranton Coal Co.; 1913, Old Forge team, Pennsylvania Co.; 1914, Lackawanna colliery, Temple Coal Co.

The officials were as follows:

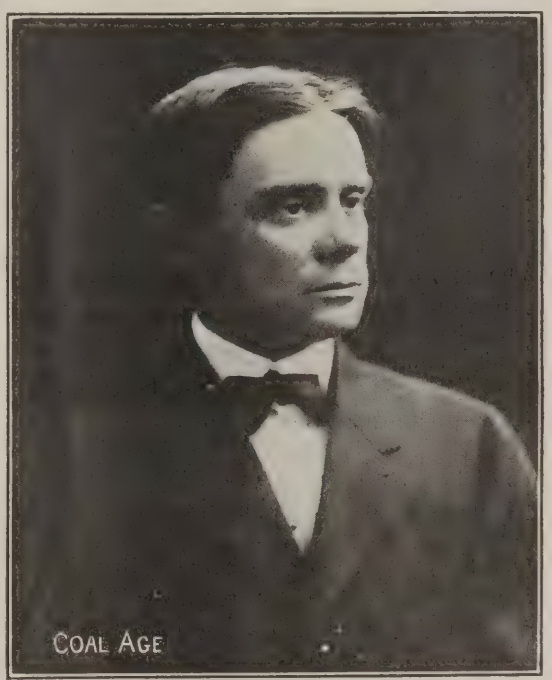
Judges—Doctors S. S. Shields, M. L. Bailey, J. W. Grant and J. B. Stinger. Secretaries—R. I. Vail, Edgar Weichel, J. G. Angwin. Managers—Dr. M. J. Shields, American Red Cross; C. E. Tobey, general manager, Delaware, Lackawanna & Western R.R. Coal Department; F. H. Coughlin, secretary, Pennsylvania Coal Co.

The personnel of the five best teams was as follows:

Lackawanna colliery outside—Harry Sax, captain; Thomas Maggs, Thomas Shultz, Reese Sax, Harry Oberts, Steve Wargo, subject.

Central colliery—Joshua Taylor, captain; Perry Clark, Joe Reid, Ivon Jones, Evan Davis, John Tompkins, subject.

Harry E. colliery—Isidor Horchester, captain; John Psolko, Frank Psolko, John Zinn, John Bigger, Frank Rosnick.



Pine Brook colliery—John Joyce, captain; Dennis Duffy, W. Morgan, Joshua James, Steve Slangan, Douglas Williams, subject.

Forty Fort colliery—Phillip Williams, captain; George Mathews, Frank Romanpomski, Andrew Tebush, Walter Jones, John Casbern, subject.

Charles S. Keith

Everybody interested in coal mining from Chicago to Salt Lake knows Charley Keith. It would be difficult to pick a man in any of our western fields who better typifies the mining industry of our central and Rocky Mountain country than he does. Mr. Keith is the embodiment of those qualities that tend to success in the great and difficult industry he serves. He is resourceful and a human dynamo of energy. In addition, he is possessed of a rare species of tact so necessary in the handling of thousands of men of differing race and habits.

Like many other successful men, Mr. Keith not only started at the very bottom, but planted himself in one particular spot and refused to budge either sideways or backward, only consenting to move in an ascending direction. No one who knows Mr. Keith doubts that the elevator which has carried him from the sub-basement to the palm garden on the roof was of his own manufacture and operated by motive power supplied by himself, for

CHAS. S. KEITH

himself. But best of all, and notwithstanding his rise in altitude, he has not forgotten his many old friends on the floors below and has not been spoiled by the broad view afforded him by the high elevation he has attained in the business world.

With it all Mr. Keith is still a very young man, having been born in Kansas City in January, 1873. His early education was secured in the public schools of Kansas, which preparatory training was followed by a college course at Fordham University. At this latter institution he obtained a "B. S." degree in 1891.

On leaving college, Mr. Keith immediately connected himself with the Central Coal & Coke Co., a corporation which he had already served as office boy. His rise was rapid, and is not ended yet, for each succeeding year tells a story of his greater achievements and increased influence.

Charley Keith is the type of man who is not content simply to measure up to a job, but rather the kind of fellow who makes the position fit himself. The remarkable record of growth of the Central Company is evidence of

his ability as an instrument of industrial expansion. His aim is to make his corporation not just a big concern, but the biggest of all.

Mr. Keith is rather an active citizen, and a useful member of practically all the organizations in his home town. At present, he is serving as president of the Kansas City Commercial Club; president of the Interstate Coal Operators Association and a member of the U. S. A. Chamber of Commerce. His business interests are mostly in lumber and coal. Aside from serving as president of the Central Coal & Coke Co., he is president of the Louisiana and Texas Lumber Co.; president of the Delta Lumber Co.; director of the Fidelity Trust Co. and director of the Metropolitan Street Railway Company.

In the social life of the Middle West, Mr. Keith figures prominently: He retains membership in the Kansas City Club, University Club, Midday Club, Commercial Club, Kansas City Country Club, Mission Hills Club, Blue Hills Club, Mercantile Club in St. Louis and Chicago Athletic Club.

Safety in Charging Dynamite

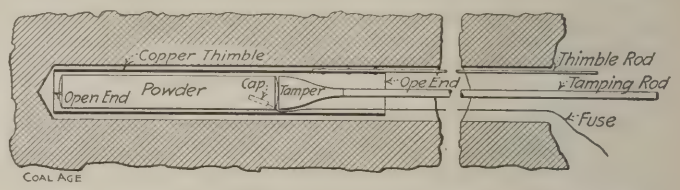
By H. N. Freeman*

There are many instances on record of dynamite going off with disastrous results when being inserted into the hole. This might be attributed to any one of the following causes:

1. The hole may not have been cleaned properly, and a small piece of coal remaining may break the cartridge and allow the powder to become distributed along the hole. This is liable to be and often is exploded either by forcing other cartridges into the hole and grinding the stray powder or by the friction of the tamping bar.

2. If the powder is not properly thawed, it will leave small particles of nitroglycerin on the sides of the hole, which are liable to be exploded by the friction of the tamping rod.

3. The hole may have been bored with drills that are not of the same gage. These leave a collar in the hole, so that when the powder is being inserted, it will jam against one of these collars.



4. There is a practice prevailing among miners to force the powder, thereby causing the premature explosion of the charge.

5. It frequently happens that in his hurry a miner may neglect to put the first stick of powder to the back of the hole. He then puts in the primer and forces it on to the powder, driving the charge back a couple of inches or more. This is a common practice among miners and a large percentage of accidents may be attributable to this cause.

The accompanying figure illustrates a device that should, I think, prove a great benefit to miners in both quartz and coal. I claim it will enable one to place his powder to the back of the hole without its coming into contact with the sides of the bore.

The charger consists of a light copper tube or thimble with a rod or handle of ⅜-in. round copper riveted to the side of the tube. The thimble is made ½ in. larger in diameter than the cartridge, and ½ in. less than the diameter of the hole. A slot is made in the tube to accommodate the fuse. The charger is open at both ends, thus enabling the tamping bar to be inserted next the powder and preventing undue pressure. Both charge and tamping bar are inserted into the hole, at the same time.

After the charge has been delivered to the back of the hole, the charger is withdrawn over the tamper, and the powder is pressed into a solid mass in the back of the hole. Some miners make a practice of splitting the paper cartridge and compressing the powder to the full diameter of the hole. This can be done more safely with the charger, as the split cartridge does not come into contact with the hole, at any point, thus eliminating those causes for premature discharge to which I have previously referred.

Section through Drillhole, Showing Charging Thimble and Charge of Powder

The chargers can be made for about 10c. each; and, if properly used, are time savers in tamping a shot, all the powder being placed in the charger before it is inserted into the hole. They are especially useful when charging a hole drilled on an angle, as the full charge may be put into the hole at one time; while, otherwise, something must be used to keep one stick in place, when preparing to insert the next one.

*Manager, The Vancouver-Nanaimo Coal Mining Co., Nanaimo, B. C., Canada.

Who Knows?

He is indeed a bold prophet who pretends to forecast either the probability or improbability of future usefulness of any raw material. As has been illustrated by the radium mineral carnotite, the mineralogic curiosity of one decade may become the valuable ore of the next. Again, the principal ore of aluminum, bauxite, was not even mentioned in a list of useful minerals published by the U. S. Geological Survey 25 years ago.

Cement Gun in Coal Mines

The Bureau of Mines in February shut down its experimental mine near Bruceton after completing the second series of tests, in order to make the annual repairs and to prepare for a new series. It is expected that coal dusts from various sections of the country will be sent to the mine in order that their explosibility limit may be tested, when the dusts are admixed with shale, clay or sand. Consequently, it is necessary that part of the explosive passages of the mine should be lined to prevent dust from the roof and coal ribs from entering into the explosion tests and affecting the results.

To line the entries with massive or reinforced concrete would be beyond the pocketbook of that part of the Bureau's work, but it occurred to the chief mining engineer that as the roof and ribs to be covered were well in the interior of the mine, that if a thin coating of cement could be placed over them, sufficiently bonded to the natural strata, every purpose would be served. Accordingly a cement gun was rented, and about 750 lineal ft. in all of the entryway has been completely coated. While the tests have not yet begun, the bonding to the walls and roof, even to the draw-slate, appears even better than ex-

pected. It was especially gratifying to note that the cement mortar appears to stick tightly to the draw-slate, which is practically clay.

If a lining like this will stay permanently, it offers great possibilities in mining. The chief mining engineer thinks the gun will be of great value around any mine, as a fireproof stopping can be quickly made, and despite the rapidity of the work, the stopping will be tight and will exclude air.

The gun is arranged on wheels and is self-contained, being drawn by a small gasoline motor, except that compressed air must be furnished from outside or else a portable compressor used.

The lining will doubtless be examined by the members of the American Institute of Mining Engineers with great interest on the occasion of their visit to the experimental mine on the afternoon of Oct. 9, to witness an explosion experiment primarily to test the efficiency of various rock-dust barriers developed by the Bureau engineers.

Colorado Operators Reply to the President's Proposition

SYNOPSIS—The operators in Colorado declare that the truce proposed would be broken like the former one and assert that any concessions to disorder are derogatory to the national government whether made to corporations or to miners. They urge that, in regard to picketing, the new agreement is less satisfactory than the state law. They point out that the new commission to be appointed by the President would have far more power over the coal corporations than any of the bodies of regulation having congressional authorization.

The letter following has been addressed to the President from Denver, Colo., by a number of Colorado operators and is dated Sept. 23, 1914.

Sir: Your letter of Sept. 5 and draft of "Tentative Basis for the Adjustment of the Colorado Strike" has been submitted to us by the parties to whom it was written, at a meeting to which the operators of all the coal mines of the State were invited.

We are in complete accord with the sentiments expressed in your letter, and appreciate the interest you have taken in the "Colorado situation."

We realize that, with the multitude of more important matters constantly engrossing your time and thought, you are, to a large degree, dependent for your information concerning the Colorado strike on the representatives of the Government of the United States who, you state, "have been actively engaged in the investigation of the whole situation and in trying to reach a dispassionate conclusion."

It is to be regretted that the character of the investigation and the previous records of these representatives selected by Secretary of Labor Wilson justify the belief that they are partisans of the men who have made necessary the presence of the Federal troops in the strike district. One of the representatives, William Fairley, was a member of the National Executive Committee of the United Mine Workers of America for Alabama, and, according to their Treasurer's report, was on their payroll during the year ended Nov. 30, 1913, and was actively engaged as an organizer and agitator in the Colorado strike in 1904.

The New Truce as Easy to Violate as the Old

The utmost sought to be accomplished by the tentative plan is the establishment of a three-year "truce" presumably between the coal-mine owners of this State and the organization known as the United Mine Workers of America, which instigated and has conducted and financed the strike.

For many reasons, we deem it unwise to enter into engagements of any character with this particular labor union, especially an agreement dependent upon a cessation of armed hostilities upon its part.

The Governor of this State, some months since, entered into an agreement of truce with the leaders of this organization, and, in utter disregard of their obligations, the striking miners, under the direction of these identical leaders, continued with renewed vigor to destroy our properties and kill our workmen. It would be imprudent to again place any reliance upon the good faith of these men.

We feel, furthermore, that a mere "truce," even if it could be enforced against the voluntary, unincorporated association and its irresponsible leaders, is but a palliative measure and can lead to nothing other than what the term itself implies—a renewal of trouble at its termination.

No reference is made nor consideration given in the "tentative plan" to the large body of men, some 9500 in number, who are now peaceably at work in the mining districts of the State, who have caused no disturbance of any kind, and whose only desire is that they be permitted to continue at work without interference from any outside source. As a matter of justice their desires should be ascertained and given full consideration. It is this body which has continued industriously at work during the last year, thus saving the public from the loss and discomfort which would have resulted from a scarcity and excessive price of coal.

A Concession to Disorder

Again, the plan proposed involves, in effect, a contract or agreement between the operators and the strikers or their leaders that both will keep the peace and obey the law for the period of three years. It appears to us that the plan is subject to fair criticism in that it implies the helplessness of government to maintain law and order and secure to every citizen his constitutional rights without the consent and approval of those evilly disposed.

We believe that a large majority of the people of Colorado agree with us that the sole issue at the present time is the preservation of law and order in the strike districts and the maintenance of the constitutional right of every man to work when, where, for whom, and upon such terms as he sees fit.

It would be fatal to the preservation of government, either national or State, for either to discuss with offenders of any character the terms upon which the laws should be obeyed and acts of lawless violence be discontinued.

Whether the blame for what has taken place in Colorado is chargeable to the operators or to the striking miners and their leaders, the plan proposed involves a bargain between government and law on the one side, and violators of the law on the other.

Operators Readily Agree to Three Propositions

Not as a matter of contract or "truce" with the United Mine Workers of America or the strikers, but with a desire to meet your views so far as possible, we will adopt and coöperate in putting into effect three of the six suggestions in the "tentative plan," and the fourth with necessary, and, as we believe, reasonable modifications.

1. "Enforcement of mining and labor laws of the State."

We have not wilfully violated any of the laws of the State, and will render every possible assistance to the civil authorities in their enforcement.

3. "Intimidation of union or non-union men strictly prohibited."

We agree to this without reservation, but the "tentative plan" provides no way of enforcing the rule.

4. "Current scale of wages, rules, and regulations for each mine to be printed and posted.

This practice is already in force in many of the mines in the State, and we will at once put the suggestion into effect at all our mines.

Employment of All But the Convicted

2. That all striking miners who have not been found guilty of violation of the law shall be given employment by the employer they formerly worked for, and where the place of the employee has been filled, he shall be given employment as a miner at the same or other mines of the company."

We are and have been willing to employ as many of the strikers as possible, without discriminating against them

for having laid down their tools, and we believe that we can give work to a very large majority of those remaining in the State. But it is quite impossible for us to agree to employ all striking miners who have not been found guilty of violence. Whether those who have participated in violence are prosecuted and found guilty or not, we cannot agree to give them employment in the mines operated by us.

In six of the counties of the State 332 of the strikers, including officers of the United Mine Workers of America, are under indictment for murder and 137 for other felonies. None of them have been tried, therefore none have been found guilty, and much time may elapse before they are tried. The personal safety of our present employees and their families, to say nothing of the protection of our property, demand that we exercise the greatest possible care in employing men from the ranks of the strikers, who have been banded together to drive our employees from our mines and to destroy our property.

The coal mines of Colorado last month (August, 1914), employed approximately 9500 men, or nearly 80 per cent. of the number employed during the corresponding month of last year—the month immediately preceding the calling of the strike. The present force of men can probably produce sufficient coal to meet the requirements of the Colorado public during the coming winter, and it is certain that no shortage can occur if the orders under which the Federal troops are acting can be so modified as to permit the many idle men who apply for work to be given employment without the limitations or restrictions now enforced by the Federal troops.

Some "Strikers" Have Never Yet Mined Coal

Some of the larger companies have closed a number of their mines, and under existing business conditions they will undoubtedly remain closed for a considerable period of time.

Many of the strikers have left the State and found work elsewhere. A considerable number have returned to work at our mines from time to time, ever since the strike was called, so that of those who originally went out on strike but comparatively few remain. Many of the men now in the strikers' camps have never worked in the mines of Colorado, but have been imported by the United Mine Workers to keep up the semblance of a strike.

Grievance Committee Mischievous

5. "Each mine to have a Grievance Committee, Etc."

This is a favorite method of the United Mine Workers' organization to foment trouble and provoke strife, although they have in many cases, notably in West Virginia, waived this demand.

In practice, it has been found that such committees have a damaging effect on the interests of both the employee and employer. The tendency of such committees is to magnify trifling and unjust complaints into great grievances, and interfere with the discipline necessary for the safety of the employees and company property, and to destroy the authority of the officers responsible for the operation of the mines.

Our employees have never asked for such a committee and we are strongly opposed to this feature of the "tentative plan."

We have always listened to and have been ready to correct any substantial grievances of our employees. There are surprisingly few complaints, except in times of strike, and such complaints are principally after-thoughts of the strikers. But to remove every possible cause for criticism we have been for some time and are now working on a plan (which we had taken up with the Governor prior to the receipt of your letter) to protect our employees against any possible injustice on the part of mine bosses, and to investigate and correct real or dissipate imaginary grievances, if any such exist. This plan, we believe, will satisfy our employees without destroying the necessary authority or influence of our superintendents and without depriving us of the reasonable control of our business.

A Commission with Unequaled Powers

Clauses five and six provide for a commission which "shall serve as adjusters or referees in all disputes (whether individual or collective) affecting wages, working and social conditions." "The decisions of the commission shall be final and binding on employers and employees." "Willful violation of any of these conditions will be subject to such penalties as may be imposed by the commission."

The unlimited authority of this proposed commission of three persons to be appointed by the President of the United States practically puts the entire control of the most important department of our business in its hands. Its power to control the conduct of our business far exceeds any of the demands of the United Mine Workers of America. A commission with such powers has never before, to our knowledge, existed or been suggested. The Interstate Commerce Commission, with all of its extensive powers for the regulation of railroads and railroad business, has no such variety or scope of authority as this proposed commission, while the decisions of the Interstate Commerce Commission are subject to review by the courts under established rules of law.

The power to regulate the wages of our employees individually and collectively, as often as demands are made, would prevent us from making any estimate of the cost of production on which to base our contracts for the sale of coal, and could be used to destroy existing competitive conditions.

The power to adjust all questions affecting working conditions will destroy the discipline necessary for the safety not only of the men but of the property.

The power to regulate social conditions would destroy the personal liberty of individuals, and is a more sweeping and comprehensive control than is claimed by either Church or State.

The decisions of this commission could not be enforced against our employees, who, if dissatisfied with the award, could leave our employ and seek work elsewhere, whereas, to the extent of our financial responsibility, the award could be enforced against us.

An unwise or unjust exercise of the powers of this commission might result in the financial ruin of any operator.

It is unfair to place our business in a position where it can, under any circumstance, be subjected to the unappealable mandates of any men or body of men however well meaning and experienced.

Operators to Agree to a Violation of State Laws

We regret our inability to agree to this suggestion of the "tentative plan."

6. Paragraph "D." "There shall be no picketing, parading, colonizing, or mass campaigning of representatives of any labor organization of miners who are parties to this truce, which will interfere with the working operations of any mine.

How the Former Truce Was Observed at the McNally Mine on Apr. 27, 1914

House at Piedmont of Rocky Mountain Fuel Co., Blown Up by Strikers, Nov. 11, 1913

Picketing is prohibited by State law, and that law can be enforced by the civil authorities. The limitations placed on the observance of this rule, as above emphasized, could be made a pretext for its constant violation.

Paragraph "G." "The suspension of a mine over six consecutive days by the company may be authorized for a cause satisfactory to the commission, but not pending any dispute."

This rule totally disregards possible market conditions and other industrial contingencies, which, in the ordinary course of the business, frequently make it necessary to suspend operations for considerable periods of time—under some conditions for a month or even longer.

The Involuntary Check-Off

"On account of the mutual benefits derived from the 'truce,' employers and employees should each pay one-half of the expenses of the commission."

Our present employees, who have not been considered in the "tentative plan," should not be asked to contribute to the maintenance of such a commission. Neither do we see how we as operators can agree that our employees will contribute to this expense except by their individual consent.

Necessity for Federal Troops

It is not our purpose to take up your time with a history of the strike and the circumstances leading up to it, nor to discuss whether the operators or strikers were responsible for the past violence, but we wish to call your attention to the fact that since you sent the Federal troops into the strike districts there has been nothing in the attitude of the coal operators to make the presence of the troops necessary, and, except for the attitude of the strikers, the Federal troops could be withdrawn at any time without endangering the peace of the district or the safety of the strikers.

On the arrival of the Federal troops in the State, the coal operators promptly complied with your proclamation by delivering up all of their arms and dismissing their guards.

On the contrary, the strikers defied your authority, gave up only a few of their arms and still gathered together in camps with arms readily available for the purpose of attacking our mines as soon as the Federal troops are withdrawn.

Our employees being now unarmed and our property defenseless, if the Federal troops are withdrawn, great destruction of life and property will surely occur.

Suggestions for Creating Peace

We respectfully suggest that the Federal troops can safely be withdrawn from Colorado when the officers and agents of the United Mine Workers of America cease to incite the strikers to lawlessness and cease to support them in idleness; or when the strikers surrender their arms and ammunition and the Governor of the State puts into effect by proclamation and enforces the law passed at the special session of the State Legislature held last May relating to the shipment, sale, and possession of arms and ammunition in the strike districts.

We shall be glad to coöperate with you in any practical measures having for their object the termination of the unfortunate labor conditions which, to some extent, still exist in this State. It is our firm conviction that the result universally desired can be obtained by a strict and impartial enforcement of the laws affecting alike strikers and operators. To this end, we take the liberty of suggesting that there be such concurrent action upon the part of the Federal and State authorities as will enable the Governor to immediately put into effect, within the limits of the disturbed district, by proclamation, the laws recently enacted by this State relating to the sale and possession of arms and ammunition, and to repeat our frequent requests that the orders to the officers in command of the Federal troops in this State restricting the mine operators in the employment of labor be so modified as to permit the employment of workmen as in normal times. Respectfully,

VICTOR-AMERICAN FUEL CO., J. C. Osgood, Chairman.
ROCKY MOUNTAIN FUEL CO., D. W. Brown, President.
BROOKS-HARRISON FUEL CO., James E. Brooks, President.
PALISADE COAL AND SUPPLY CO., Henry Denman.
PRIMROSE COAL CO., H. B. King, President.
NATIONAL FUEL CO., H. Van Mater, President.
ROYAL FUEL CO., H. Van Mater, President.
GORDON COAL CO., Wm. Dick, President.
NEW MAITLAND COAL CO., J. T. Thompson, President.
WILLIAMSBURG COAL CO., Simon P. Smith, President.
ROYAL GORGE COAL AND FIRECLAY CO., E. G. Bettis, President.
EMPIRE COAL MINING CO., R. D. Marthens, Treasurer.
BIG FOUR COAL AND COKE CO., P. M. Peltier, President.
HAYDEN BROS. COAL CORPORATION, Lewis A. Hayden, President.
GARFIELD MINE LEASING CO., E. Horstman, President.
CONSOLIDATED COAL AND COKE CO., C. L. Baum, President.
ALLIANCE COAL CO., D. A. Cannon, President.
CEDAR HILL COAL AND COKE CO., D. M. Harrington, President.
PATTERSON & SONS COAL CO., El Paso Co., Alex. Patterson.
PIKE'S PEAK FUEL CO., John Tait Milliken.
SANTA FE COAL CO., S. S. Murphey, President.
TURNER COAL CO., James B. Dick, President.
RUGBY FUEL CO., George D. Kimball, General Manager.
WALSENBURG COAL MINING CO., George Fruth, President
BALDWIN FUEL CO., H. E. McElwain, President.
BREEN COAL CO., J. P. Breen.
AZTEC COAL MINING CO., J. S. Autrey, President.
YAMPA VALLEY COAL CO., P. M. Peltier, President.
FREDERICK FUEL CO., D. M. Simpson, President.
ROUTT COUNTY FUEL CO., E. L. Prentiss, President.
CHICOSA FUEL CO., J. V. Sickman, President.
UNION COAL AND COKE CO., Jas. V. Bowen, President.
HUERFANO COAL CO., S. S. Murphey, President.
SUNNYSIDE COAL MINING CO., W. F. Oakes, President.
SOUTH CAÑON COAL CO., H. F. Nash, General Manager.
OAKDALE COAL CO., William B. Lewis, President.
MUTUAL COAL CO., S. S. Murphey, President.
TEMPLE FUEL CO., F. R. Wood, President.
NORTHERN COLORADO COAL CO., J. S. Siple, General Manager.
GRAND JUNCTION MINING AND FUEL CO., H. M. McNeil, Secretary and Treasurer.
NEW FOX COAL CO., D. E. Evans, President.
MOFFAT COAL CO., S. M. Perry, President.
LEYDEN COAL CO., S. M. Perry, President.

The undersigned operators, who have made agreements with the United Mine Workers of America and are employing union labor, join in the views expressed in the foregoing letter in relation to the "tentative plan" therein referred to:

RAPSON COAL MINING CO., W. W. Curtis, President.
CARBONADO COAL MINING CO., J. B. Hutchinson, President.
MINNEQUA COAL CO., E. F. McGowan, President.
P. K. HARMON.
BLACK CAÑON FUEL CO., Talton F. Crane, Secretary.

Don'ts for Rescue Corps

Note—From book of instructions of Susquehanna Coal Co., Wilkes-Barre, Penn.

1. Don't fail to notify the man in charge of apparatus at once in case of trouble.
2. Don't tamper with the apparatus. It is ready for service.
3. Don't use old batteries in your lamp.
4. Don't hurry when using the apparatus.
5. Don't put the apparatus on alone and go into the danger zone without having someone make a thorough inspection of the apparatus. Don't go into the danger zone alone.
6. Don't use old cartridges in dangerous work.
7. Don't fail to look at pressure gage before going into the danger zone.
8. Don't fail to inspect all connections before putting the apparatus on.
9. Don't fail to keep in communication with the other helmet men.
10. Don't take helmet off in danger zone.
11. Don't forget that the rescue of men is the first consideration.
12. Don't forget to send for the first-aid immediately.
13. Don't chew tobacco in the helmet.
14. Don't disturb too much wreckage on first inspection It might start something.
15. Don't fail to note conditions.
16. Don't fail to report conditions noted.
17. Don't fail to report any abnormal behavior of the apparatus.
18. Don't forget to return immediately if you think apparatus is not working properly.
19. Don't take chances—PLAY SAFE.
20. Don't fail to follow instructions.
21. Don't go into a strange mine without a guide.
22. Don't expect to be able to work as hard or as fast with the apparatus on as without it. You are carrying a load.
23. Don't, under any consideration, when exploring a mine in which electricity is used, get in contact with bare wires, unless you are sure the current is off.
24. Don't fail to take extra electric lamps with you from the rescue station—some may not work properly.
25. Don't forget the apparatus is only good for two hours.

Editorials

Buy a Bale!

The cotton growers say, "Let every one buy a bale of cotton so as to enable the cotton farmers to go on raising crops during the war." And it is an extremely popular movement, but it will probably result in a glut of cotton and if no one buys the crop, the land next year will be devoted to something else and serve an almost equally useful purpose.

But if the war causes bad times and the demand for coal becomes slack as is likely to happen, will everybody buy a dozen tons of coal so as to keep the miners busy who otherwise would be idle? Is not their idle labor as much an economic loss as the cotton farmers' idle land, if it really becomes idle? Is their lack of wherewithal any less distressing than that of the cotton growers? Is there, in short, anything more logical in "Buy a bale" than in "Buy a cellar-full of coal?"

We think not, but we are not surprised at the argument in the opposing direction; for our care of the farmer has exceeded our care for any industry except in the matter of tariff. In that one direction of glaring discrimination, we have more than made up for all our false sentiment and tender solicitude for the farmer.

Compensation in Pennsylvania

The Susquehanna Coal Co., with its affiliations, mines about 5½ million tons of coal per year. It has perhaps as large a number of first-aid teams per thousand of tons of production as any company in the anthracite region, and we might add in United States, for the first-aid teams in the hard-coal mines are easily leaders in numbers and efficiency. At the recent meet at Shamokin, the Susquehanna had 44 teams in the field.

The recent contest at Terre Haute, Ind., was considered by everyone a marvelous success, yet only 29 teams competed. There is no question about the energy with which the Susquehanna employees, with Morris Williams and Robert Quinn at their head, are striving for safety.

Last year the company spent $50,000 for safety inspectors alone, and there is evidence that the expenditure was not without its reward in the saving of life and limb. A year ago the address of the president of the company, Morris Williams, was on the introduction of safety inspection. This year his talk was mainly on compensation for injuries.

He stated that a prominent coal operator had remarked to him that it was a conscienceless nation which would send its men into the battle and not provide for the widows and orphans and it was an industry without shame which would send its men into danger and not protect, by compensation, the dependents of those who might be killed at their daily task. Mr. Williams believed that a compensation bill should be passed at once which would protect the wives of miners and others from the prospect of closing their lives over the steam of a washtub.

A few years from now, such remarks will be merest platitude, so fast do we move forward. But today, Mr. Williams' remark is regarded a. a bold statement. We trust that many other operators will support Morris Williams in his stand for workmen's compensation. In this connection, it is interesting to note that in 1912, at the summer meeting of the Coal Mining Institute of America, H. S. Endsley, counsel for the Cambria Steel Co., also advocated this provision.

It is true that in many other states, operators have come forward and prepared compensation bills, but in most cases they were face to face with conditions which threatened to bankrupt the companies. Unreasonable juries were bringing in verdicts unfair to the coal corporations and which threatened to drive them out of business. Any compensation bill was an improvement on the conditions existing.

But in Pennsylvania, a compensation enactment will replace a condition whereby the operator is almost entirely relieved of responsibility and the company which advocates the passage of such a measure has nothing but its conscience to direct it.

The Coal Trade and Requirements of Peru

We have heard much of the expected changes that would be wrought in American shipping and trade by the Panama Canal. There is perhaps no portion of the world which will be more strongly influenced than the western coast of both North and South America, while probably no commodity will be more vitally affected than coal.

So far as South America is concerned, the countries lying east of the Andes, with the possible exceptions of the United States of Colombia, and Venezuela, produce practically no coal of their own. West of this mountain range, however, and included therein, the countries are a little more fortunate in their natural fuel supplies. Both Chile and Peru produce coal, but neither country is sufficient at the present time to its own needs.

In Peru, while it is well known that certain regions have considerable coal deposits, these districts lying less than 100 miles from the coast, but two mines have been operated during recent years. These were worked by the Cerro de Pasco Mining Co., at Goyllarisquisga and Quishuarancha, producing between 600 and 800 tons per day. This coal, however, finds its use in the blast and reverberatory furnaces of the company, and during 1913, there were imported into Peru from foreign countries, 150,660 metric tons (166,074 American short tons) of coal and coke.

The principal obstacle, in the way of developing the coal properties of the land, appears to be limited railroad facilities, and the heavy constructional expense involved in building the same in the rough and mountainous coal-bearing districts.

The value of the coal and coke importations into Peru in 1913, and the countries of their origin, are as follows: Australia, $106,630; Belgium, $38,259; Chile,

$27,933; Germany, $318,198; Netherlands, $45,266; Great Britain, $768,424; United States, $111,544; total, $1,466,227.

That Great Britain has a long established trade between the west coast of South America and Wales, accounts in large measure for the heavy importation of English coal. The vessels bringing this fuel return with sugar, cotton or nitrate, from either Peru or Chile.

The prices paid for Welsh coal alongside in lighters at Callao ranges from 46s. to 50s. or from $11.17 to $12.16 per ton, according to the prevailing freight rate. The importation from Germany consists almost exclusively of coke, which is used by the various mining companies for smelting. The German products alongside at Callao cost about 42s. ($10.20) per ton.

The importations from Australia are of low-grade or gas coal, used mostly by the local gas companies. This costs from 37s. to 40s., or from $9 to $9.72 per ton, f.o.b. Callao.

There are ample facilities for discharging coal at Callao, either to lighters or barges, or upon the docks, the latter, however, costing about 72c. per metric ton. The port charges are: Tonnage dues, 10c. per registered ton; hospital dues, 2c.; dock-companies dues, 6c.; light dues, 1c.; stevedore, loading and discharging, 10c.; ship's broker entrance, $30; clearance, $20. There is no duty upon coal.

Few if any briquettes are now being employed in this country, and within the past 12 months or thereabouts, the Peruvian Corporation, which operates and controls approximately 80 per cent. of the country's railways, has burned oil instead of coal in its locomotives, large quantities of the former product being now produced in this country.

With the opening of the Panama Canal and therewith the ability of many American coal producers to send cargoes direct to the west coast ports from such American shipping points as New Orleans, Mobile and Newport News, it would appear that many of these shippers would be able to successfully compete in this market with European or Australian producers. Certainly American operators receive a lower price for their product at the mine's mouth than do those of Great Britain or Continental Europe, while the distance that the American coal would be required to travel in order to enter the west coast ports of South America is shorter by some thousands of miles than the distance from the European or Australian sources of supply.

Evolution in Trade Conditions in Indiana

Eastern coals for a long time completely predominated the Indiana markets, and it is only in recent years that the local product has come into any extensive use. As a result of an aggressive educational campaign on the part of the Indiana operators, consumers were prevailed upon to give the local fuel a thorough test, with the result that these have, in many instances, been adopted for permanent use.

The Indiana coal has had the reputation locally of being somewhat "dirtier" than other fuels. To overcome this prejudice, operators have been careful to hold their best grades for these markets. As a result of persistent and well directed efforts, the local fuels are now displacing the higher-priced Eastern coals, such as the Hocking Valley, sales of which have been materially reduced. It is now estimated that the Indiana mines furnish from 50 to 75% of all the domestic fuel consumed in the state. A careful estimate made in Indianapolis a few years ago, showed that about 30 per cent. of the sales there were of Indiana coal, and it is conservatively estimated that these have at least doubled since that time. In the southern part of the state about 90 per cent. of the consumption is the local product, but on the eastern border, where the freight rates are more favorable to the Ohio, Pennsylvania and Virginia coals, there is still a moderately large consumption of these grades. As regards the steam coals, the Indiana mines have a practical monopoly of these markets.

Prevention of Accidents from Hoisting

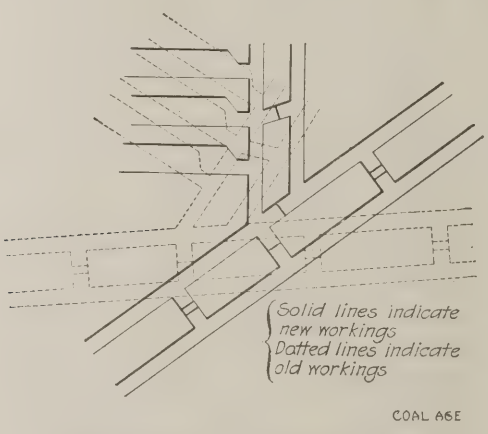
A serious accident at a large colliery has drawn attention to the necessity of adopting precautionary measures in hoisting men from new shafts during sinking operations. An investigation committee recommends that always during sinking, the hoisting engineer should be protected from inclement weather by the erection of a permanent structure over him. They further suggest that overwinding apparatus should always be in use; that portable lamps should be provided instead of carrying an electric cable down the shaft with a single globe lamp attached to it. It is further advised that two sets of engines for raising men be provided, so that one hoisting outfit will always be ready in case of emergency. The provision of roped ladders is likewise recommended.

Inflammation Limits of Gaseous Mixtures

It is interesting to note that British investigators have proved conclusively that minute sparks can be passed through an explosive gaseous mixture without exploding it, although the temperature of the spark is above the generally accepted ignition temperature of the mixture. It was observed, however, that some slight combustion took place in the path of the spark. When the intensity of the spark was increased, the gases exploded.

These experiments would seem to indicate that gas mixtures differ considerably in their ignition temperature. In other words, a gaseous mixture diluted with inert gas, or under reduced pressure, requires a hotter spark to fire it than when it exists under normal conditions. Methane (the chief constituent of firedamp) differs from hydrogen in having a higher ignition temperature and a more prolonged process of oxidation for complete combustion. It is for this reason, in all probability, that in the case of an inflammable mixture containing methane, the source of heat necessary to inflame the mixture must be more intense and must be longer in contact with it than in the case of a hydrogen mixture.

The question of using the energy of large quantities of coal by other means than as a steam producer will have to be faced by coal operators in the not distant future. The truth of this statement is supported by the increasing use of oil for fuel purposes. Why can't we devise a successful method for extracting fuel oil from our coal seams?



Discussion By Readers

Method of Working Underlying Coal Seam

Letter No. 2—Referring to the proposition submitted by Mr. Lyman, COAL AGE, Aug. 29, p. 357, asking for a discussion of the best method of working a 4½-ft. seam of coal, underlying a 9-ft. seam that had been previously worked out and abandoned, I would say that the method he suggests of driving the entries to the boundary and then working out the coal on the room-and-pillar retreating system, appears to me to be the most favorable, from an economical standpoint.

In the absence of any reliable data in regard to the exact location of the pillars still remaining in the old workings and which would prove a menace to the successful working of the lower seam, I would suggest the following as a precautionary measure:

In order to prevent, as far as possible, an excessive roof weight along a line of least resistance in the new workings, these should be laid out in such a manner that the lines of the entries and rooms in the lower seam will

A PROPOSED PLAN OF WORKING

make an oblique angle with similar lines in the old workings. I have attempted to illustrate this idea in the accompanying sketch, in which the new workings in the lower seam are indicated by the full lines, while the dotted lines represent what may be assumed to be a general plan of the old workings in the seam above. By this means, much of the danger that would otherwise be encountered, owing to a general correspondence of the lines of weakness in both seams, would be avoided. To still further minimize the danger, I would suggest that all openings be made as narrow as possible, consistent with economy and safety, and that larger room-and-entry pillars be provided than would otherwise be necessary.

However, should it be impossible to obtain such a general plan or knowledge of the old workings and it became necessary to develop the lower seam independently, I think that any undue roof stress, owing to unfavorable conditions in the seam above, could be detected by careful observation of their effect in the new workings. I believe, that, by carefully observing the effect produced upon posts, timbers and ribs, it would be possible to adopt precautionary measures, in the way of reinforcing the supports in the lower seams or changing the line of working, so as to overcome the difficulty.

I. C. PARFITT.

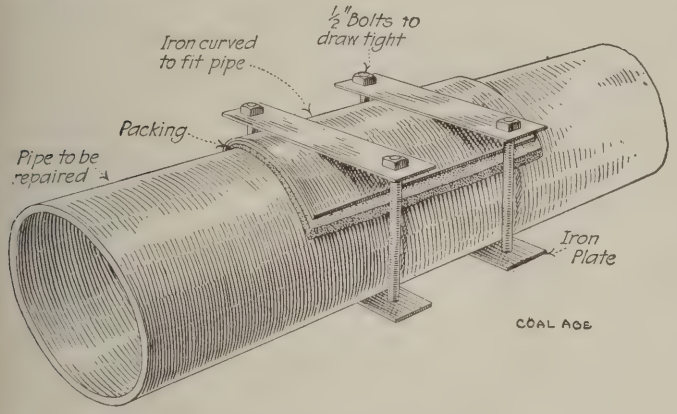
Jerome, Penn.

Letter No. 3—In answer to the request for a full discussion of the difficulties presented in the mining of an underlying seam of coal, under the conditions described by Mr. Lyman, COAL AGE, Aug. 29, p. 357, I would suggest that this seam be worked the same as though the coal lying 40 ft. above it was still solid or as though the upper seam were never there. I consider that if the coal in the upper seam has been worked out anyway clean, it will not endanger the work in the seam below.

Under the conditions existing at the present time in coal mining, I do not approve of the method often suggested of driving the entries to the boundary line before starting rib-work; or, what is called the "retreating plan." In order to put out coal at a reasonable cost, there must be a certain amount of rib-work. If the mine is properly laid out, no danger or loss of coal will result by robbing the pillars as the work is advanced. The retreating plan means a large investment for entry driving, track and timber that pays no dividends.

In considering this question at the present time, it may be assumed that the mine is to be equipped with electrical mining machines, which will concentrate the work. The seam being 4½ ft. thick, it is fair to estimate on using a short-wall chain machine capable of producing 100 tons of coal per day, and to determine the number of these machines that will be required for the desired output of the mine. Also, the style of gathering motor to be used in this low seam can be determined and the method of haulage properly planned.

With this information in hand, it is possible to lay out the mine intelligently, with respect to ventilation, haulage and drainage. I would suggest the adoption of the three-entry system for the face headings, using one for haulage and making this the intake airway, another for the return airway and the third for drainage. I would drive the butt entries 250 ft. apart and turn face headings off these, on 120-ft. centers; then open the rooms on the butts, driving them 12 ft. wide, on 25-ft. centers. With a 7-ft. cutter-bar, the ribs could be taken out in two slabs.



Knowing the required output of the mine, it is possible to estimate the required number of flats and the number of butt rooms that should be working on each flat; and to estimate the necessary volume of air for the ventilation of the mine. As the work progresses, and the roof conditions become known, it may be possible to modify this plan by driving wider rooms or in other ways that will produce better results.

PENNSYLVANIA ENGINEER.

Oliphant Furnace, Penn.

Repairing a Cracked Pipe

N. G. Near's clever method of repairing cracked and dented pipe as described in COAL AGE, Sept. 12, p. 425, calls to mind a method I have often employed to repair a leaky pipe, and which is illustrated in the accompanying figure. This method, on a low-pressure line or where the leak is small, may be regarded as giving results that are practically permanent.

THE PATCH IN PLACE

The blacksmith, taking as a model a pipe the size of the one to be repaired, hammers a small piece of sheet iron into a curve to fit the pipe. A piece of packing is then placed over the crack, the curved iron laid on the packing; and yokes are used on the curved iron and on the pipe on the opposite side from the leak. The patch is then drawn tight by ½-in. bolts, until the leak is stopped.

I have secured good results from this method, and it may be applied quickly and easily from materials always at hand, about the mine.

GEO. N. LANTZ.

New Straitsville, O.

The Ohio Situation

In COAL AGE, Aug. 29, p. 354, Coal Operator, writing on The Ohio Situation, objects to the 47c. rate asked by the miners for run-of-mine coal. He states as follows:

> However, the injustice of this lies in the fact that the Hocking Valley miners have been reduced 2½c. per ton, while an advance of 2½c. per ton has been placed to the credit of the eastern Ohio miners, which allowances, as far as the operators are concerned, certainly give the Hocking Valley operators an advantage of 5c. per ton over last year's prices.

Granting that a state-wide uniform scale, in the present instance, secures to the Hocking Valley operators a slight advantage, it must be remembered that in the past the eastern Ohio operators enjoyed a similar advantage through the operation of a uniform scale. I will endeavor to prove this advantage by the use of Coal Operator's figures.

In making his estimate, he states that last year's price was 69.5c. per ton for screen coal; and that the percentages of slack, for the Hocking Valley, Cambridge and eastern Ohio districts, were 28, 34 and 36 per cent., respectively. The corresponding percentages for screened lump, in the same respective districts would therefore be 72, 66 and 64 per cent. Therefore, for every ton of run-of-mine coal, the eastern Ohio operators paid $0.64 \times 0.695 = \$0.4448$; while the Hocking Valley operators paid for the same, $0.72 \times 0.695 = \$0.5004$. The difference in favor of eastern Ohio was $0.5004 - 0.4448 = \$0.556$; or, approximately, 5½c. per ton.

Considered from a miner's standpoint, the basic justice of the measure is apparent. It requires the same labor to produce a ton of coal, regardless of the percentage of slack; and the miners feel that *equal labor demands equal compensation.* It is this principle that induced the Hocking Valley miners to sacrifice 2½c. per ton for the benefit of the eastern Ohio miners.

GEO. N. LANTZ.

New Straitsville, Ohio.

The Foreigner in Mining

The contrast in tone of letters Nos. 3 and 4, COAL AGE, Sept. 12, p. 440-1, is very striking. These letters relate to the education and treatment of the foreign element in mining.

In letter No. 3, Mr. Parfitt depicts a class utterly void of inherent virtue. He describes them as possessing "a dominant characteristic that is the result of centuries of association with a type of civilization wholly un-American" and a menace to the country. The tone of Mr. Hogarth's letter, No. 4, on the contrary, is optimistic. It teems with encouragement for the mine official and hope for the foreign miner, recking not his foreign birth, ancestors and doctrine.

While one of these writers would debar the foreigner from the liberty he seeks and condemn him for characteristics that are the results of previous environment and for which he is obviously not responsible, the other takes him by the hand and welcomes him to the enjoyment of a freedom, which, it may be assumed, he appreciates, having fled the tyranny and injustice of his own country. While one writer declares this element incapable of improvement and the time and labor devoted to their education as wasted, the other says, "The better they are treated, the better men they become." While one writer is narrow, illiberal and unjustifiably harsh in his judgment, the other is broad and humane; his expressions bubble over with the milk of human kindness.

Personally, I am pleased to be in a position to testify to the loyalty of the foreign miner toward his employer, generally; also, to his ability to mine and load coal or perform any other task in regard to which he has been properly instructed. Experience has taught me that, instead of the time spent in teaching and instructing these men being wasted, it is well spent and productive of good results. Close observation of what many of these men have accomplished only strengthens one's admiration for them, in view of their dominant characteristics, which are described by the first writer as "cunning, subterfuge and duplicity." I am free to confess that these qualities more often describe members of our "pit committees," who have been born and bred in freedom and should possess higher qualities.

Many mine officials can endorse the statement of the second writer, in reference to taking these men "as they come from the old country, fresh from following the plow and watch them grow to be good miners and good citizens generally." And, I doubt if any mine official can recall a foreign miner declaring his belief that "earthly rulers exercise their authority by divine appointment." In-

stead of portraying such a belief, the evidence at hand points most emphatically to the other extreme. The tragic deaths, in recent times, of the kings of Greece, Portugal and Italy, and lastly the assassination of the Crown Prince and Princess of Austria, bear ample testimony that the mind of the foreigner is not "indelibly impressed" as described.

There is still another aspect to this discussion, which the first writer has seemingly overlooked. Whatever the foreign miner is or is not, we know, certainly, that he *is* a first-class man for loading coal. His ignorance of American institutions is excusable and a thorough knowledge of them dispensable, as far as the work in hand is concerned. Indeed, it would be a calamity if this class of immigration were to be replaced by a more highly educated type. We may ask, what would be the effect on the coal industry if none but the "morally educated" and "mentally developed" were admitted to our shores. It should cause no surprise that the foreign miner, for a time, fails to appreciate and often misjudges the privileges that are his in this country. Transported suddenly from his environment of ignorant superstition, which is intensified by the combined efforts of king and clergy to limit his freedom, it is only natural that the lifting of this load should cause the man to rebound accordingly. The fact reveals the wealth of vitality awaiting development under the kind heart and willing hand of a Hogarth to direct it aright.

The foreigner coming to this country judges of its laws and customs by the treatment he receives. His personal contact with people is to him the best and only interpretation of the laws of the country. The harsh treatment of an employer develops a corresponding line of conduct in the workmen. To the credit of this class of immigration, it may be said that the immigrant of a few years ago now sees his sons occupying important positions of honor and trust in all branches of industry throughout this country, notwithstanding the handicap of their dominant characteristics. Experience at the Ellsworth collieries has proved that it pays to educate and instruct the foreign element and to assist him to acquire both the language and a knowledge of what constitutes true citizenship.

In closing, allow me to suggest that all superintendents who are desirous of generating and fostering a proper spirit toward their foreign employees should carefully read Mr. Hogarth's letter and then present a copy of the same to each foreman in his charge, with the instruction that its contents should form the keynote of their conduct toward this class of labor.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

Cube Root, Direct Method—(For illustration, $\sqrt[3]{14{,}706.13}$).

Rule—Beginning at units place, divide the number into periods of three figures each, completing the right-hand period of a decimal, if necessary, by adding ciphers.

$\overline{14}\ 706.130$

Observe the greatest perfect cube contained in the first period on the left and write its root as the first figure of the required root.

$2^3 = 8$; $3^3 = 27$; *hence*, $\sqrt[3]{14} = 2+$ . . . $\overline{14}\ 706.130\ (2$

Subtract the cube of the root found from the first period on the left, and to the remainder annex the second period to form the first dividend.

$14 - 2^3 = 14 - 8 = 6$ . . . *1st dividend*, 6,706

For the first trial divisor, take three times the square of the root found.

$3 \times 2^2 = 3 \times 4 = 12$ *1st trial divisor*, 12

To find the second figure of the root, divide the first dividend, exclusive of the last two figures, by the first divisor. Now, cube the root, and if the cube exceeds the first two periods, diminish the last figure found.

$67 \div 12 = 5+$; $25^3 = 15{,}625$, *high* . . . *partial root*, 24

Subtract the cube of the root found, from the first two periods, and to the remainder annex the third period to form the second dividend.

$14{,}706 - 24^3 = 14{,}706 - 13{,}824 = 882$ . . . *2nd divd.*, 882,130

For a second trial divisor ,take three times the square of the root found.

$3 \times 24^2 = 3 \times 576 = 1728$ . . . *2nd divisor*, 1728

To find the third figure of the root, divide the second dividend, exclusive of the last two figures, by the second divisor. Then, cube the root, and if the cube exceeds the first three periods, diminish the last figure of the root found.

$8821 \div 1728 = 5+$; $245^3 = 14{,}706{,}125$, *low* . . . *root*, 24.5+

Observe the position of the decimal point in the root corresponds to its position in the given number.

Following is the manner of performing the operations:

$\overline{14}\ 706.\overline{130}$ (24.5+ *required root*

$2^3 = 8$

$3 \times 2^2 = 12)\ 67|06$

5 $25^3 = 15.625$, *high, write* 4 *in root*

. . . . . .

14,706

$24^3 = 13{,}824$

$3 \times 24^2 = 1728)\ 8821|30$

5 $245^3 = 14{,}706{,}125$, *low*

. . . . . .

14,706,130

$245^3 = 14{,}706{,}125$

5 *last remainder*

The Coal Age Pocket Book

Fifth Root, a Practical Method—The following is a simple and practical method of extracting the fifth root of a number. The method can be applied to any degree of approximation desired, and is correct as far as it is carried.

Numbers Less Than 100,000—The fifth root of the number is less than 10, and the integral part of the root is a digit. To find this digit, proceed as follows. (For illustration, $\sqrt[5]{23{,}415}$).

Rule—Fnd the two consecutive digits whose fifth powers embrace the given number. The lesser of the two digits is the integer of the required root.

$7^5 = 7 \times 7 \times 7 \times 7 \times 7 = 16{,}807$

$8^5 = 8 \times 8 \times 8 \times 8 \times 8 = 32{,}768$ . . . *integer of root* 7

To find the first decimal figure of the root, take the greater digit four times as a factor, and the lesser digit once. If the product of these five factors exceeds the given number, take the greater digit one less times and the lesser digit one more: and continue thus till the product of the five factors is less than the given number. Divide the sum of these five factors by 5, and the quotient will be the required fifth root of the number to the first decimal.

$8 \times 8 \times 8 \times 8 \times 7 = 28{,}672$, high

$8 \times 8 \times 8 \times 7 \times 7 = 25{,}088$, high

$8 \times 8 \times 7 \times 7 \times 7 = 21{,}952$, low

$\frac{8 + 8 + 7 + 7 + 7}{5} = 7.4$ . . . . root, to one decimal, 7.4+

To find, in turn, succeeding decimal figures of the root, divide the given number by the fourth power of the root already found; add the quotient to four times that root: and divide by 5.

$(23{,}415 \div 7.4^4 + 4 \times 7.4) \div 5 = 7.48$ . . . *root to two decimals*

$(23{,}415 \div 7.48^4 + 4 \times 7.48) \div 5 = 7.478$ . . . *root to three decimals*

Numbers Greater Than 100,000—The fifth root of the number is greater than 10, and the integral part of the root will then contain two figures. (For illustration, $\sqrt[5]{722{,}180}$).

Rule—Find, by trial, two consecutive numbers whose fifth powers embrace the given number. The lesser of these two numbers is the integer of the required root.

$14^5 = 14 \times 14 \times 14 \times 14 \times 14 = 537{,}824$

$15^5 = 15 \times 15 \times 15 \times 15 \times 15 = 759{,}375$ . . . *integer of root*, 14

To find, in turn, succeeding decimal figures to complete the root, divide the given number by the fourth power of the root already found; add the quotient to four times that root; and divide by 5.

$(722{,}180 \div 14^4 + 4 \times 14) \div 5 = 14.9$ . . . *root to one decimal*

$(722{,}180 \div 14.9^4 + 4 \times 14.9) \div 5 = 14.85$ . . . *root to two decimals*

Fifth Root of Decimals—(For illustration, $\sqrt[5]{2.58}$).

Rule—Complete any decimal period, if necessary, by adding ciphers till the period contains five figures. Then, disregarding the decimal point, follow the rule for integers.

$2.58 = 2.58000$ . . . *as integer*, 258,000

Finally, pointing off as required, $\sqrt[5]{2.58} = 1.208+$

Inquiries of General Interest

Comparison of Coal and Oil as Fuel

Will you kindly answer the following questions relating to the comparative value of coal and oil when employed as fuel in the production of steam:

1. What weight of coal is used, under ordinary conditions in practice, to vaporize 1 lb. of water; or, in other words, under ordinary conditions in boiler practice, what weight of water will be vaporized by the burning of 1 lb. of coal?

2. What amount of commercial oil is required, in ordinary practice, to vaporize 1 lb. of water?

3. What arguments, if any, are there in favor of burning coal and against oil, for the production of steam, assuming that it were possible to obtain heat units at the same cost, in each case?

In this connection, I have under consideration an apparatus that I hope may revolutionize the methods of steam production.

H. N. Freeman, Mgr.,
Vancouver-Nanaimo C. M. Co., Ltd.
Nanaimo, B. C., Canada.

In answering these questions, it must be remembered that much will depend on the character of the coal or oil used, with respect to their respective calorific values. For the purpose of estimate, the calorific power of good bituminous coal may be taken as, say 14,000 B.t.u. The calorific power of petroleum suitable for fuel purposes varies with the specific gravity of the oil, from 18,000 to 21,000 B.t.u. Also, in boiler practice, very much depends on the adaptation of the fuel burned to the particular type of boiler in use. This is true whether coal or oil be employed as the fuel.

With a fair coal and good boiler, it is usual to estimate a consumption of 4.5 lb. of coal, per hp., per hr. Then, since 1 boiler hp. is equivalent to the evaporation of 34.5 lb. of water, from and at 212 deg. F., it may be estimated that 1 lb. of bituminous coal will evaporate $34.5 \div 4.5 =$ say 7½ lb. of water, from and at 212 deg. F.

It is estimated, further, that 1 lb. of crude oil (Beaumont, Tex.) having a specific gravity of 0.92 and a calorific power of 19,000 B.t.u. per lb., when properly burned under a boiler, will evaporate 14.8 lb. of water per hr.

Now, assuming that heat units can be purchased for the same price, in the case of both coal and oil, the ratio of heat values, oil: coal, is 19: 14; but the ratio of evaporation, oil: coal, is 14.8: 7.5. Therefore, on this basis, every dollar invested in oil will only purchase, by weight, $^{14}/_{19}$ of what the same money would buy if invested in coal, but the oil will evaporate 14.8/7.5 times as much water. Hence, the relative values of these two fuels, on this basis, is

$$\frac{14}{19} \times \frac{14.8}{7.5} = 1.38$$

That is to say, every dollar of investment in oil yields, in this case, an evaporation 1.38 times as great as a dollar invested in coal.

A Gaseous Mine

There seems to be much confusion in regard to the question as to what is a gaseous mine, in the meaning of the Bituminous Mine Law of 1911 (Pennsylvania). There are numerous references in the bituminous law, making certain requirements in mines "wherein explosive gas is being generated in such quantities that it can be detected by an approved safety lamp." These references would seem to make it clear that, in the meaning of the law, every mine is a gaseous mine, in which gas is generated in quantities sufficient to be detected by an approved safety lamp.

There seems to be serious doubt, however, as to whether this would be a correct answer to the question, "What is a gaseous mine," if such a question were to be asked in a bituminous mine examination. The doubt as to the correctness of this answer arises from the reading of Sec. 2, Art. 28 of the law, which is as follows:

> The provisions of this act as to mines, or portions of a mine generating explosive gas in quantities sufficient to be detected by an approved safety lamp, shall not apply to any mine wherein explosive gas is being generated only in live entries.

Again, Sec. 3 of the same article reads:

> The provisions of this act shall not apply to any mine employing less than 10 persons inside the mine, in any one period of 24 hr.

These sections of the law make it clear that, unless gas is generated elsewhere than in "live entries," in quantities sufficient to be detected by an approved safety lamp, the mine is not to be classed as a gaseous mine, in the meaning of the law; and is not subject to the restrictions and regulations required by previous sections of the law in relation to the generation of gas in mines. Also, a mine employing less than 10 persons underground is not to be classed as a gaseous mine, in the meaning of the law, regardless as to whether such mine is or is not generating gas in sufficient quantities for detection on the lamp.

This is an important matter, not only because the question may be asked at examinations, but more particularly because there are many mines, in the bituminous region of Pennsylvania, that are being worked as gaseous mines and fulfilling all the requirements of the law, in reference to safety lamps, shotfirers, permissible explosives, etc. I am not saying that these mines should not adopt these precautions; I believe they should. But, according to the clearly defined meaning of Sec. 2, Art. 28, they are not required by law to adopt the precautions they are using of necessity.

James T. Reynolds, Fireboss,
Pine Run Co.
Vandergrift, Penn.

[A full discussion of this question is invited by mine inspectors, mine foremen and firebosses.—Ed.]

Examination Questions

Wyoming Questions (1912)

(Answered by Request)

Ques.—Why does gas sometimes fire in a safety lamp and not explode the gas in the air surrounding the lamp?

Ans.—Under different conditions, degree of explosibility of the gas-charged air and the use of lamps of different construction, the firing of the gas may fill the entire chimney of the lamp with flame; or small balloons of flame may form and rise in quick succession within the chimney; or sharp crackling sounds or reports may be heard. The cooler metal of the gauze prevents the passage of the flame outward by cooling the small streamlets of gas and air passing through the mesh, below the point of ignition of the gas.

The flaming of a lamp shows a more or less uniform gaseous condition of the atmosphere in the combustion chamber. The explosive condition is not as acute, in this case, as that producing a crackling noise or sharp explosive reports in the lamp, which fact indicates a less uniform gaseous condition and a higher degree of explosibility of the gas-charged air. The explosion of the mixture, in this case, presumably requires a greater intensity of the igniting flame, resulting in explosions occurring only in direct contact with the flame of the lamp.

Ques.—What is the water gage corresponding to a ventilating pressure of 7.8 lb. per sq.ft.?

Ans.—The corresponding water gage is $7.8 \div 5.2 = 1.5$ in.

Ques.—Find the ventilating pressure in pounds per square foot, when the water gage reads 2.5 in.

Ans.—The unit of ventilating pressure, in this case, is $2.4 \times 5.2 = 12.48$ lb. per sq.ft.

Ques.—With the fan at a constant speed and the airways of equal length, which will pass the greatest amount of air: four airways, each 4x5 ft. in section or one airway, 8x10 ft. in section; and why?

Ans.—A constant speed of fan means, approximately, a constant power on the air. For a constant power, all the airways being of equal length, the quantity of air in circulation is directly proportional to the total area of passage and inversely proportional to the cube root of the perimeter. In other words, the quantity ratio is equal to the area ratio multiplied by the cube root of the inverse perimeter ratio.

In the present case, the total areas and perimeters are as follows:

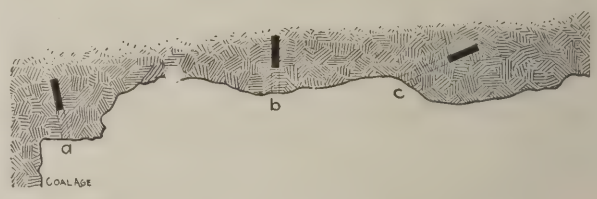
Four airways, 4x5 ft.;

$a = 4\ (4 \times 5\ ) = 80\ sq.ft.;\ o = 4 \times 2\ (4 + 5) = 72\ ft.$

One airway, 8x10 ft.;

$a = 8 \times 10 = 80\ sq.ft.;\ o = 2\ (8 + 10) = 36\ ft.$

The total areas being equal, the area ratio is 1, and the inverse perimeter ratio is $^{36}/_{72} = 0.5$; hence,



$$quantity\ ratio = 1 \times \sqrt[3]{0.5} = 0.793$$

That is to say, four airways, each 4x5 ft., will only pass 0.793 of the quantity of air the same speed of fan will circulate in a single airway, 8x10 ft., all the airways being of the same length.

Ques.—What are the dangers of shooting off the solid in dry and dusty mines, and what precautions would you take to prevent accident?

Ans.—The practice of shooting off the solid frequently causes what is termed by the miners a "tight shot." When the method is properly employed, there is no danger in its use, except under exceptional conditions where the coal is extremely friable or inflammable and the seam is generating gas. In many cases, the coal is not mined; it is never sidecut; and too often the shot is bound by projecting tops or bottoms, which give the powder little or no opportunity to perform its work of breaking down the coal.

In the accompanying figure are shown a rib-shot, at *a*; a "dead" shot or hole, at *b*; and a "grip" shot, at *c*. The two shots last named are employed in the practice of

BLASTING AT THE FACE OF A ROOM

shooting off the solid. Commonly, the miner selects a favorable place in the face of the coal, as at *c*, where a grip shot, if not too deeply laid, will perform good work. The temptation is too strong, however, to locate the charge too deeply on the solid; or even to put in a dead hole drilled normal to the face of the coal, as at *d*.

The tendency, in the past, has been to use too heavy a charge; depending on the strength of the powder to blow down the coal, and not assisting the shot to perform its work by properly undermining the coal. The result is a tight shot that blows out its tamping, without breaking down the coal. Almost the entire energy of the powder is, in this case, expended on the air, which produces a heavy concussion and raises a cloud of dust. The blast is accompanied with a volume of flame that is projected from the hole with great force, igniting the cloud of dust and causing a local explosion that may, and frequently does, develop into a mine explosion involving the entire underground workings. To prevent such occurrences, miners should use a limited charge of powder sufficient only for the work it must perform in breaking down the coal. In every case, the coal should be properly mined or the shot so located that it is free to perform its work.

Ques.—What useful purposes do overcasts and undercasts serve, in mine ventilation; and which of these do you prefer, and why?

Ans.—Overcasts and undercasts are two forms of air bridges or air crossings employed to carry one air current over or under another. They serve as a means of ventilating cross-headings, without the use of doors. Overcasts are generally preferred as they cannot be flooded and are easier to keep air-tight.

Coal and Coke News

Harrisburg, Penn.

Testimony was presented in the Dauphin County Court on Sept. 25, by the United Mine Workers' organization of the Schuylkill and Lehigh regions, that some men returned by the Examining Boards of the several districts as eligible for mine foremen's and assistant mine foremen's certificates had never been employed in the actual cutting of coal at the face, and that others had been so employed only a short time.

The testimony was given in the mandamus proceedings brought against the Chief of the Department of Mines to restrain the issuing of certificates of eligibility to some of the men recommended by the boards, and the case brought by the union officials against the issuing of certificates to certain men, who they allege never had had actual experience at the face.

Involved in the action is the question whether the term "five years' practical experience as a miner" means five years' employment inside the mines or five years in the actual cutting of coal. For years it has been alleged that men were returned as competent to act as mine foremen and assistant mine foremen who did not possess qualifications for these positions, and some months ago the mine workers' union brought suit mentioning the names of men who, it was declared were not experienced in digging coal.

Some of these witnesses were heard. Mine inspectors and an expert employed by the Philadelphia & Reading Coal & Iron Co. to ascertain the efficiency of miners, testified as to the understanding of the term "miner" in the anthracite coal region, saying that it meant the man who gets out the coal, but they did not confine their opinion strictly to the cutting or blasting of that mineral.

The Attorney General's department has held in two opinions on the language used in the law that the five years' practical experience meant employment in the mine, not necessarily that a man had to be a digger of coal for the period of five years. And it was on the strength of this opinion that many of the candidates appearing before the examining boards took the oath that they were miners before entering the examinations.

It was the opinion of the mine inspectors, that the term, "five years' practical experience as a miner" should include not less than two years at actual cutting or blasting coal at the face, for in that time any intelligent man could become an expert at this part of mining and about three years' experience at setting timber and double timbering, building brattice, batteries, removing gas, track-laying, etc., but, that such occupations as driving, door tending, tending foot or top of shaft or slope should not be considered in the term of "practical miner." It was also brought out that it is the men with general experience that make the best foremen, for it was pointed out that a man might work at the face for 20 years cutting coal, and never know how to brush gas, place a double set of timber, or lay a good track in his place which he is supposed to do or timber a locality where a fall has occurred. It was stated that with but few exceptions it was the men with general all around experience that stood the examination.

It was argued that the number of persons competent for filling such important positions as foreman, and assistant mine foreman in the first place is very small. It was shown that a mine foreman or assistant foreman should be a person somewhat acquainted with geology, so as to know the formation surrounding the locality where he is employed. He should understand and know something about mine maps; while it isn't necessary for him to be a chemist, he should know the different gases met with in the anthracite coal mines. He should also have some knowledge of engines, for today most of the coal is being transported by air or electric locomotives; mine pumps he should be well acquainted with; also the sinking of shafts and slopes; ventilating fans and the method of operating the same; he should also be familiar with track laying.

He should be able to timber shafts, slopes, and gangways; in fact, he should be an all around miner. He should be acquainted with all the different seams of coal, so as to determine the size of pillars to support the roof, according to the nature of the coal and the depth of the mine. In case of an accident he should be cool-headed and determined in carrying out his instructions and a fair judge of human nature. There is no doubt that it would add greatly to his success to know how to mine coal properly in the different seams and on different pitches, but the great question is, "can enough men be selected from the face of breast or gangway to meet with those requirements, which are necessary to make a successful mine foreman or assistant mine foreman?"

If the parties back of this case are sincere in dealing with a question of practicability, why advocate things that might be detrimental to the same cause, for at the last two sessions of the legislature a great pressure has been brought to bear on the mines and mining committee to pass a law making all mine foremen eligible for mine inspector without standing an examination.

Final argument will be heard on Oct. 12.

PENNSYLVANIA

Anthracite

Hazleton—While many towns in the anthracite field have suffered serious results from the prolonged drouth, Hazleton and vicinity have not yet felt its effects. None of the local collieries or factories have curtailed operation on account of a scarcity of water.

Shenandoah—The No. 12 washery at Coal Dale has resumed operation after being idle almost all summer undergoing extensive alterations.

Bituminous

Pittsburgh—The H. C. Frick Coke Co., as noted in our issue of last week, has completed a remarkable working model of the Phillips plant of the company. This shows the mine tipples, power plant, boiler houses, machine shops, lamp houses, and even the bath house. This exhibit will be included with other displays of the U. S. Steel Corporation at the Panama-Pacific Exposition next year, showing various methods adopted to prevent accidents in the corporation's safety-first campaign.

Church Hill—The Dutch Hill mine of the Hedstrom Coal Mining Co., of Buffalo, situated in the Allegheny Valley, Church Hill post office, has been sold to the Church Hill Mining Co. It has a capacity of about 300 tons a day, and has been in operation most of the time of late. The new company is controlled by the Monterey Coal Co., and will be superintended by A. J. Watson of that firm.

WEST VIRGINIA

Elverton—Determined to capture the men who on Sept. 10 fired from ambush on unarmed workmen and the manager's residence, the Branch Coal & Coke Co. has recently increased the amount of the reward offered from $1000 to $5000.

Charleston—The first definite results of a failure of a labor employing corporation in West Virginia to come under the provisions of the Workmen's Compensation Division of the Public Service Commission Act and pay its premium was recently made public. The Piney Mining Co. elected to come under the provisions of the statute last October when it first went into effect, but has never paid any of its premiums. One of its employees, Antonio De Francisco, was awarded a pension for permanent disability for injuries received in this company's mine in the sum of $7.98 per week for life. The Commission found, however, that the mining company has never paid its premium and the pension could not be paid. Francisco brought suit, and secured a judgment of $5000. It is said that the company's total premiums for the year would not have exceeded $2500.

Bluefield—Official figures covering shipments of coal from the West Virginia fields over the Norfolk & Western R.R. during August have been published in detail, showing a slight decrease in business as compared with the preceding month. From the various fields covered, shipments for the month totaled 2,450,808 tons, divided as follows: Pocahontas, 1,227,621 tons; Tug River, 93,179 tons; Thacker, 286,572 tons; Kenova, 105,725 tons; Clinch Valley, 134,408 tons; Miscellaneous, 4210 tons; Williamson and Pond Creek connection, 91,813 tons, and other railroad connections, 257,280 tons.

ALABAMA

Birmingham—The Alabama Co., one of the largest producers of coal, coke and iron in the state, has completed its improvements at Ironton, this work including the relining

of No. 2 furnace. While the furnace was idle the company rebuilt and improved its washers and constructed a concrete dam to provide an abundance of water. All of the coal mines are running, and the ore mines, with one exception, are running full time.

Clanton—In boring for water for the use of the local water-works company, contractors have struck oil and coal. New machines are on the ground and are now boring for these products instead of water. It is reported that the coal is of good grade and thickness, and further investigations are being rapidly pushed.

TENNESSEE

Oswego—Representatives of the United Mine Workers of this section are meeting here in connection with a committee representing the operators in the Jellico district. Satisfactory results have been reached at all conferences held heretofore and it is trusted that an agreement will be reached without difficulty.

Knoxville—Large numbers of miners and others interested in that industry are expected to gather here on Oct. 15, for the proposed miners' field day which is being prepared for conditionally. J. M. Webb, officer in charge of the local station of the Federal Bureau of Mines, is awaiting further instructions from headquarters before proceeding with preparations for this event.

KENTUCKY

Owensboro—Damage superficially estimated at $1200 was done to the superstructure of Malinger's mine, operated by Frank Schultz, near here, recently when fire broke out in the buildings on the surface. A quantity of powder in kegs was exploded and it was several hours before any attempt could be made to extinguish the flames, the heat was so great. It is as yet impossible to estimate the damage down in the shaft, though the upper timbers were badly burned. Repairs will be made immediately. There was no insurance.

Whitesburg—Coal shipments from the new operations at Wayland and Weeksbury, on Beaver Creek, north of here, have been doubled and production is at the rate of 40 cars a day and still larger increases are promised for the immediate future.

Pineville—The mines, leases and all other property of the Big Hill Coal Co., of Bell County, were knocked down for $1100 to H. B. Hauger, of Richmond, Ky., representing the bondholders, at a sale held here by the commissioner of the Federal court recently. The price named is so small, it is expected here that the Court will hardly confirm the sale, as the property of the company is understood to be worth many thousands of dollars. The company's holdings include about 1000 acres of coal land on the left fork of Straight Creek and the mine equipment is said to be exceptionally good and installed at heavy expense. The mines at one time were operated with much profit and their failure is attributed to inefficient management.

OHIO

Columbus—While it is only a little over a month since the new mine-run system of paying for coal mined in Ohio has been in force, some of the operators are speculating on the question if it has increased the cost of mining. Some are of the opinion that it has not increased the cost while others say that an advance of approximately 8 per cent. in the cost of producing coal has resulted from the changed conditions.

Martins Ferry—It has been announced that the Blockhouse mine at Brilliant has resumed work. This operation was ordered by the Federal Court on May 20 to operate under the 47c. rate and was immediately closed down because it could not make money.

Considerable excitement has been created by the circulation of a rumor to the effect that the Lorain Coal & Dock Co. is contemplating dismantling one of its largest mines and moving the equipment to the Hocking district. Officers of the company refuse to discuss this matter.

INDIANA

Terre Haute—Mines in this vicinity which make a specialty of coal for domestic use have been working full time for some weeks past. Other mines depending mostly on orders for steam coal, especially screenings, are running on an average of about four days per week. There are more than enough cars for the output, and railway officials say they have so planned ahead that there will be no shortage of cars this winter.

Vincennes—An unidentified man was killed under a fall of coal and two others severely burned in a gas explosion at Indiana Creek recently. Three hundred men were in the mine at the time of the explosion, and it took half an hour to effect their rescue.

Brazil—The Association of Block Coal Operators recently declined to have a conference with the mine workers officials of their district over the discharge of a miner at De Camp mine No. 4 for the alleged reason that he did not patronize the company store. This is the first time for several years that the miners have raised the company store question. There are few of these stores in the mining districts of the state now.

ILLINOIS

Pana—A fire which recently broke out in the Tower Hill coal mine east of Pana, threatened the mine's destruction with enormous loss to the owners. This fire was started from a gas explosion in an entry caused by a blown-out shot. The flames spread rapidly, but all the men were gotten out safely.

Marion—The Illinois Hocking mine, which has been idle since the workings caught fire about 18 months ago, was recently sold by the receiver to Jacob Goodall. It is understood that the price paid was $6000, the property being subject to the miners' wages, which are still held against it. It is believed that an effort is being made to reopen the property.

Millstadt—The High Prairie mine, the largest open strip pit in southern Illinois, which has been idle for the past seven months, is expected to open up in the course of the next 10 days.

Murphysboro—Blair mine No. 1 on the M. & O. is practically worked out, and unless some arrangements now under way are perfected, whereby some additional acreage can be secured, the mine, it is expected, will be abandoned within the next 30 days.

COLORADO

Denver—Of the number of men indicted by the Las Animas County grand jury in conection with the coal strike war, 78 have been arrested. John R. Lawson is charged with 12 murders and with one case of arson. It is recommended that Deputy Attorney-General West represent the state in the prosecution, for the reason that the district attorney is in such sympathy with the striking miners as "must inevitably embarrass him to be called upon to prosecute these cases."

UTAH

Salt Lake City—The coal producers of Utah have united in requesting the United States Government to construct at the naval coaling station on San Francisco Bay, a terminal that will make it possible to deliver Utah coal to the Pacific fleet at that point. The local operators have received some encouragement from the government and are confident that coal used by the United States Government on the coast will be supplied by Utah. This will mean an added production of about 100,000 tons to the annual output of the state.

PERSONALS

J. W. Reed, of Jenkins, Ky., has been appointed instructor in mining machinery at the Kentucky State University School of Mines, at Lexington, to succeed T. J. Barr, who has been made professor of mining engineering.

W. K. Kavanaugh, president of the Southern Coal, Coke & Mining Co., of St. Louis, is at the present time on an extended trip along the Atlantic Seaboard of South America. He is now in Venezuela, looking into a future market in South America for Illinois coals.

G. A Gent, for many years an operator in Williamson County, Illinois, and until recently a resident of St. Louis, and well known in coal trade circles throughout this section, has leased for development 2500 acres of coal lands from the Crystal Block Collieries Co. The property is in Eastern Kentucky.

CONSTRUCTION NEWS

Hazard, Ky.—The Hazard-Dean Coal Co. has just completed the installation of its $15,000 electric power plant, to supply the power used in the company's workings. F. J. Walcott superintended the installation of the plant.

Youngstown, Ohio—Plans have been prepared by the Carnegie Steel Co. for the construction of a byproduct coke plant. The plans provide for 56 Koppers ovens having a capacity of 16 tons each daily. The byproducts will consist of tar, gas and amonia sulphate.

Hartshorne, Okla.—Plans have been prepared by the Rock Island Coal Mining Co., covering electric hoists and electric equipment for shafts Nos 9 and 10, to be installed next spring. At No. 10 the hoist shaft is now down 600 ft., and the air shaft 400 ft. At mine No. 9 at Alderson the hoisting shaft is down 680 ft., and slope 42 it is now down to 1000 ft.

Coshocton, Ohio—The local directors of the Ohio Cannel Coal Co., as well as capitalists from St. Louis, Mo., are contemplating arrangements for the development of the company's mine in Bedford Township. Those owning a controling interest in this project are S. C. Priest, of Walhonding; George P. Heckle, of St. Louis; John Orr, of Warsaw, and Simon Ashcraft, of West Carlyle.

Athens, Ohio—The Hocking Power Co., which is erecting an immense power plant at Floodwood, Ohio, for the purpose of supplying coal mines in this vicinity with electric current has closed a contract with the city of Athens, by which it takes over the city electrical plant at $16,000. The company has also secured a franchise from the city government to furnish current for a period of 25 years.

Charleston, S. C.—The Southern Ry. has awarded the contract for the construction of modern coal dock facilities at Charleston which will enable the Virginia & Southwestern Ry. and the Southern Ry. to handle coal from the fields of the South to this port. The dock, which will be built by the Wellman-Seaver-Morgan Co., of Cleveland, Ohio, will be constructed on property on the Cooper River containing about 120 acres, and having more than 4000 ft. of river front. The plant is designed to deliver coal to vessels at the rate of not less than 2000 tons per hour. About $450,000 will be expended in this work.

NEW INCORPORATIONS

Richmond, Va.—An amendment has been filed to the charter of the Mason Coal & Coke Co., a West Virginia corporation, reducing its capital stock to $135,000.

Seattle, Wash.—The Bolcom-Sligh Coal Co., of Seattle, has been organized with a capital of $10,000, by Charles R. Sligh, H. S. Bolcom, W. M. Bolcom and W. Y. Henry.

Tacoma, Wash.—The Summit Coal Co., of Tacoma, has been organized with a capital of $10,000 by H. M. Shovlain, James Marucha, Louis Sonney and Helen Schmitz.

Joplin, Mo.—The Higgins Land & Mining Co. has been organized with a capital stock of $80,000. The incorporators are F. S. Higgins, D. E. Miller and C. J. Martin.

Muskogee, Okla.—The Fidelity Fuel Co. has been incorporated here, with a capital stock of $10,000, by E. H. Bradley, Scott Kelly of Muskogee, and Fred Raurk of Kansas City.

Peoria, Ill.—The Gorman Coöperative Coal Co. has been organized to mine, sell and deal in coal. The incorporators are James Gorman, Gustav Forsten, Sam Angelo, Maurice Gorman and Alva Pitcher.

Brookville, Penn.—The Dilltown Smokeless Coal Co. has been organized with a capital of $5,000. The incorporators are E. E. Henderson, of Brookville; T. R. Williams and E. E. Hewitt, of Punxsutawney.

Charleston, W. Va.—The Jackson Coal Co., of Charleston, has increased its capital stock from $5000 to $570,000, and will soon take over 6000 acres of coal land in Jackson County, Ill.

Boston, Mass.—The Canadian Atlantic Coal Co., Ltd., of Boston and Richmond, N. S., has been incorporated under the

laws of Massachusetts with an authorized capital of $1,250,000, comprising 2500 shares of preferred stock and 10,000 shares of common. The preferred is 10 per cent. cumulative.

Carthage, Mo.—A certificate of incorporation has been issued to the Hugo Mining Co., of Carthage, with a capital stock of $3200. The incorporators are Louis Gratz, Mack Logan, Charles Wright and R. F. Glenn, all of Carthage. This firm is now developing mining properties near Joplin.

Bonanza, Ark.—The Woodson-Barr Coal Co. has been organized here, with M. M. Woodson, president; John Barr, vice-president, and Harry Reinhardt, secretary and treasurer, to further develop coal mines. Daily capacity now 300 tons. The name was changed from the Woodson-Strickland Coal Co.

Heberton, W. Va.—The Willis Branch Coal Co. of Herberton, Fayette County, has been organized with an authorized capital of $50,000. The chief works will be in the Fayette district, and the incorporators are Thomas K. Laing, M. P. Laing, L. E. Hiner, George W. Waring and Carl M. French, all of Beckley.

Charleston, W. Va.—A charter has been issued by the secretary of state to J. V. Thompson and others, of Uniontown, Penn., for a $2,000,000 coal company to be known as the Wetzel Coal & Coke Co. to take over and hold 19,250 acres of coal in the Clay and Church districts in Wetzel County. The chief works will be located on the Baltimore & Ohio R.R. near Littleton, and the main office and headquarters will be in Fairmount.

INDUSTRIAL NEWS

Easton, Penn.—The Thomas Iron Co., of Easton, recently blew in its No. 7 blast furnace at Alburtus, using as fuel part coke and part anthracite.

Washington, D. C.—By a viva voce vote, the Senate, on the afternoon of Sept. 26, passed the Alaska Coal Land Leasing bill, which then went to the President for final approval.

St. Louis, Mo.—The Southern Coal, Coke & Mining Co. has secured the Union Pacific R.R. contract for the coming season, which calls for 300,000 tons of Illinois coal.

Mobile, Ala.—Inaugurating the export of Birmingham coal to South America by way of the port of Mobile, the Uruguain steamer "Domingos J. De Silva" cleared recently for Buenos Aires, Argentina, with a cargo of 2964 tons of Alabama fuel.

Victoria, B. C.—The Manaimo Gas Co. of Victoria has succeeded in manufacturing standard illuminating gas of uniform quality from low-grade coal-mine refuse. The process has been in daily operation at Nanaimo for the past six months. The company has also successfully piped this gas as fas as Victoria, about 60 miles.

Columbus, Ohio—Arrangements were recently completed for a conference of traffic managers of the various commercial organizations of Ohio with the traffic managers of railroads in Central Traffic Association territory to be held at Columbus, Oct. 2, to discuss matters relative to the increase of five per cent. in rates permitted by the Interstate Commerce Commission.

Birmingham, Ala.—A cargo of briquette pitch, valued at $60,000, is being loaded by the Barrett Manufacturing Co. for Genoa, Italy. The cargo, which is being handled through a London broker, is being loaded on the L. & N. R.R., and will amount to about 5600 tons. This shipment is not due to the war, as this company has previously made shipments to the same consignees.

Chattanooga, Tenn.—Title to the plant site in Alton Park donated by the Chamber of Commerce to the Chattanooga Gas & Coal Products Co., has been transferred to the Central Trust Co., of New York trustee, for part security on the coke company's first mortgage, six per cent., six-year sinking fund gold notes to the amount of $500,000. President Lewis T. Wolle and others, agree to similarly transfer all other property which may from time to time be acquired, the usual phraseology being used.

Sharon, Penn.—The United States Steel Corporation has held up appropriations for improvements to many of its mills here and elsewhere, owing to unsettled financial conditions. Some time ago this corporation appropriated $500,000 for additions to the coking plant of the Carnegie Steel Co., at Farrell, for the manufacture of the byproduct, benzol. Plans were completed and preparations being made for beginning the work, when orders came to hold up the proposition. It is said that this corporation will make only those repairs which are absolutely necessary.

Wheeling, W. Va.—The coal traffic on the Baltimore & Ohio R.R. since the 1st of September has been the heaviest in the history of the line. From that date on, an average of between 600 and 800 cars of coal have been handled daily. The major part of this traffic is being brought to Benwood Junction by way of the Short Line and Ohio River Road. The largely increased coal traffic being handled by the road has been created by the long strike in the eastern Ohio field; 90% of the West Virginia coal is going to the ports of Lorain and Cleveland for shipment up the lakes.

Columbus, Ohio—The Baltimore & Ohio R.R. Co. has promulgated a new set of reweighing rules, applicable to coal cargoes which will become effective Oct. 24. According to B. F. Nigh, secretary of the Michigan-Ohio-Indiana Coal Association the new rules are much fairer than those in vogue previously. The application of Mr. Nigh for new rules which was to have been heard by the Ohio Public Utilities Commission, Sept. 25, was postponed because of the action of the Baltimore & Ohio and it is not likely that they will be brought up again.

Birmingham, Ala.—Dr. A. Crovetti, of Genoa, Italy, was in Birmingham recently accompanied by Walter L. Loeb, of New York, as interpreter looking over the field with a view to placing an order in Alabama for 50,000 tons of coal per month for steel works in Genoa, which Dr. Covetti represents. Cables are now being exchanged between Genoa and the New York offices of Birmingham corporations, and if financial arrangements are satisfactory the order will be placed in this district. Railroads are figuring on cars, and if the sale is consummated the coal will be shipped through Mobile, Pensacola and New Orleans.

Philadelphia, Penn.—Fuel shipments on the Pennsylvania R.R. east of Pittsburgh and Erie in August, with the exception of anthracite, fell off from the figures of the same month of the previous year. They were also smaller for the eight months' period, the only increase being in anthracite. The number of tons of this latter fuel carried in the month was 805,585, the increase being 93,134. Of bituminous, 4,299,810 tons were hauled, being a decrease of 262,529 tons; 792,656 tons of coke were handled, being a decrease of 368,828 tons. The total tonnage was 5,898,051, being a decrease of 539,223 tons. During the eight months' period, a total of 45,842,432 tons of fuel were handled. This was a decrease over the same period of the preceding year of 4,136,942 tons.

Philadelphia, Penn.—When, on Aug. 1, communications were interrupted betweeen the German factory and the American distributing and manufacturing agency of the Hess-Bright Manufacturing Co., steps were immediately taken by the American branch to provide manufacturing facilities in order to supply ball bearings of the sizes wherein shortages in the stock then on hand might occur. Although much of this work is being done outside of the Hess-Bright factory, it is in strict accordance with specifications and must pass the same rigid inspection as the goods heretofore imported from Germany. At the present time, although bearings are now being shipped from Berlin, the firm is proceeding on the independent basis of manufacturing here.

Owensboro, Ky.—Sale of all the property of the Fern Hills Coal Co. is asked by a suit filed in the Circuit Court here by trustee for the bondholders of the company. Paul Lehman, Edwin Hodde, A. J. Kirst, W. V. Doogs and Charles Powell, holders of five of the sixty $1000 bonds issued five years ago by the coal company are plaintiffs and numerous defendants are named, including the receiver of a defunct bank, among the assets of which were 35 of the same bonds. Interest on the bonds is alleged to have been defaulted for 30 days, making unpaid bonds immediately due, according to their provisions. All of the coal company's property, consisting of coal rights, tipple and necesssary operating equipment, was mortgaged for the bondholders' benefit and sale of the property to satisfy their claims is asked.

Toronto, Canada.—The new railway rates and regulations in force in Western Canada since Sept. 1, have improved shipping conditions so that the output of the mines of the Canadian Coal & Coke Co. in Alberta will be largely increased. At the Pacific Pass Colliery on the headwaters of the Pembina River, connected with the Grank Trunk Pacific by the Coal Spur branch, development has reached a point where an output of 2000 tons per day would be possible. The present production of 700 tons per day, employing a force of 150 men, it is proposed to increase as the company is now competing for the Winnipeg market and will also enter the field westward to Prince Rupert. The St. Albert mine operated by the same company has a seam 7½ ft. thick at a depth of 320 ft., which has been developed under difficulties owing to quicksand, which are now obviated by a concrete lined shaft. About 25 men are employed but this force will be increased during the winter as the demand warrants.

Coal Trade Reviews

General Review

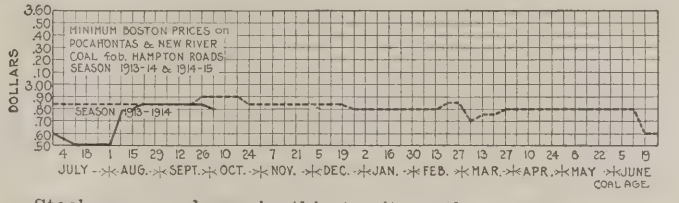
Domestic grades of anthracite in strong demand, but steam sizes are heavy. Bituminous still slowing down, though prices are well maintained. Industrial demand suffering from the generally adverse conditions.

The anthracite market is steadily improving as the season advances, the recent cool weather having had a particularly beneficial effect. Domestic consumers who deferred buying during the discount period in the summer have been forced into the market by the lower temperatures, and this has created a general activity. The Lake business is also somewhat larger at the moment, but it has now reached the maximum for the season. The situation is not so favorable in the steam sizes, which are feeling the same general heaviness that characterizes the bituminous trade. Substantial discounts on the regular circular are noted on the small sizes, but the domestic grades are holding firm at the full circular. Operations in the mining districts are at practically full capacity.

The export bituminous trade continues in fair volume, but there is a growing uneasiness over the curtailed steam consumption. The one encouraging feature in the situation is the fact that the market is showing indications of an excellent undertone, and will no doubt respond quickly to any improvement in general conditions. The better grades of coal are still rather closely held. Prices are well maintained so far, and there is an absence of the customary large tonnages of demurrage coal, which usually characterize a weak market. It is none the less a fact that shipments are confined almost entirely to contracts, requisitions on which are reduced to a minimum, and there must be some favorable developments shortly to avoid a slump.

The Pittsburgh market is still losing ground in all directions; the steel mills are only operating at half capacity, with indications of a still further reduction shortly, and the manufacturing demand is again tapering off. The market has been thoroughly combed for orders, but consumption is at the minimum, and will continue so until there is a general resumption in industrial lines. Canadian manufacturing is heavily curtailed, so that fuel requirements are restricted and American operators are inclined to be suspicious of this business in any event. The market is very irregular, circular prices being purely nominal and obtained only on the very best grades.

The Ohio situation is unsatisfactory, the domestic grades having now suffered a relapse in sympathy with the steam coal. Lake shipping has reached the maximum, though it will probably continue until the close of navigation. Operators in the Southern markets are showing a more persistent interest in the export business than is generally the case through the East and the opinion is freely expressed that there will be a considerable tonnage shipped to South America during the next six months. Business locally is stagnant, the railroads suffering more or less severely from the depressed conditions prevailing in both the cotton and steel industries.



The Middlewestern trade is still contending with a completely demoralized steam market and a heavily oversold domestic trade. Production of the latter sizes is far below market requirements, and some substantial advances in quotations have been recorded. Had it not been for the general unsettlement following the European war, the Middlewestern operators believe they would have had an unusually prosperous season.

ATLANTIC SEABOARD

BOSTON

Large volumes of Pocahontas and New River coals at the loading piers, and facing a dull market. Prices being shaded. Georges Creek fast catching up on old orders. Pennsylvania grades firm. Water freights at a minimum. Anthracite demand is streaky.

Bituminous—The steadily increasing accumulation of coal at Hampton Roads does not speak well for the state of the market. The $2.85 price is still maintained in most cases but concessions are known to have been made and it is generally felt that lower prices will prevail before the end of October. The export trade shows a further decline in tonnage, and taking everything together, the difficulty of arranging foreign exchange and in some instances the 60- and 90-day settlements, the amount and the character of the offshore business that was offering so freely in early August has proved much of a disappointment. It was relied upon at least to steady the Tidewater situation, but with this prop to the market materially weakened, and the generally slack condition in manufacturing in New England, it is hard to see how a slump can be prevented.

Stocks are so large in this territory that even shipments for application to contracts are scaled down to the smallest tonnages. The few cargoes that come forward only partly sold, met with slow response. It is certain that the nominal price of $3.78 on cars Boston will have to be shaded materially if any buying is to be developed.

Further signs are observed of a better supply of Georges Creek available at all points. The shippers were far behind on their orders during August and September, but the prospect is more than favorable now for normal shipments the remainder of the season.

The Pennsylvania grades show no special change. All-rail the demand is better than at tide, but in no direction can the market be called anything but slack. The low-priced coals are at a standstill.

Water Freights are at a minimum, 65c. being the rate on large vessels, Hampton Roads to Boston. There is almost no inquiry, and certain of the steam colliers have been chartered to run to the West coast.

Anthracite demand is not quite up to expectation. The extremely unseasonable weather in late September doubtless had some effect and from now on there should be more business for the retailer. The shippers are loading a fair amount of coal but the orders are mostly for odd lots to patch out local stocks and the movement is by no means as steadily as is usually the case at this season.

Wholesale prices on bituminous are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.90@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.15@2.80	2.50@2.90	2.92@3.02	
New York*	2.40@3.10	2.80@3.20	3.22@3.32	
Baltimore*	.....	.....	2.85@2.95	
Hampton Roads*	.....	.....	.....	$2.80@2.85
Boston†	.....	.....	.....	3.60@3.78
Providence†	.....	.....	.....	3.63@3.73

* F.o.b. †On cars.

NEW YORK

Bituminous stagnant but with a strong undertone. Contract shipments restricted and there is no prompt market. Anthracite opening up in a satisfactory manner. Cool weather stimulates buying.

Bituminous—It is generally felt that the soft-coal market has touched bottom. The trade is certainly dull, almost to the point of complete stagnation, and yet there is a strong undertone that indicates excellent recuperative powers when the industrial situation improves. The salient features of the current situation are the impressive manner in which prices are being maintained and the general absence of demurrage coal, together with the shortage of the high-grade varieties. The absence of demurrage coal is due, in part at least, to an evident change in the policy of the Western Maryland Ry., this road having been chiefly responsible for the excess accumulation of demurrage coal at Tidewater during the previous slump in the market during the summer. Shipments from that section are now restricted considerably below the general average for the bituminous mines.

The general movement on contract is only fair, some companies, such as public service corporations, taking their usual full quotas but others curtailing heavily. Stocks in the hands of the consumers are at a minimum, and when the long expected upturn sets in, there will undoubtedly be a heavy initial demand until normal stocks are again accumulated. An important exception to this rule is one of the large coal roads which has been stocking heavy tonnages in order to keep the operators on its lines going; its surplus is now so large, that even it has been compelled to suspend for the time being at least.

The New York market continues quotable on the following basis: West Virginia steam $2.50@2.60; fair grades Pennsylvania, $2.55@2.65; good grades of Pennsylvania, $2.70 @2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

Anthracite—The hard-coal season is opening up in an entirely satisfactory manner. The recent cold weather has stimulated considerable activity among buyers, many of whom deferred stocking during the summer because of the unsatisfactory financial conditions. The mines are working on practically full time and the line trade is particularly strong, especially in New England.

In the domestic grades, egg coal continues practically the only long size being offered in a few isolated instances down to the April circular; however, the lower temperatures are having a beneficial effect upon it, and it is now beginning to move better. Stove coal continues in the heaviest demand and shortest supply, shipments being substantially less than market requirements in all directions, both all-rail and at tidewater. The demand for chestnut is increasing and few sales are reported at less than the full circular.

The situation in the smaller sizes is not so favorable. Pea coal is the strongest there being a heavy movement all-rail with occasional premiums noted but at Tidewater the situation is easier and the full circular is not always obtainable. All the steam grades are generally heavy with the possible exception of barley; it is particularly difficult to find prompt disposition for No. 2 buckwheat, and there is some accumulation of this size.

The New York anthracite market is now quotable as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.10	$4.65@5.10	$5.05	$4.60@5.05
Egg	5.35	5.10@5.35	5.30	4.80@5.30
Stove	5.35	5.35@5.45	5 30	5.30@5.40
Chestnut	5.60	5.50@5.60	5.55	5.45@5.55
Pea	3.55	3.45@3.55	3.50	3.40@3.50
Buckwheat	2.80	2.70@2.80	2.50@2.75	2.25@2.75
Rice	2.30	2.10@2.30	2.00@2.25	1.50@2.25
Barley	1.80	1.70@1.80	1.75	1.50@1.75

PHILADELPHIA

Anthracite stimulated by cool weather. Better demand for prepared sizes, but steam grades little heavy. No perceptible improvement in bituminous.

Anthracite—The cool weather of last week has had a perceptible influence in the buying of anthracite. Dealers are not overwhelmed with orders, but claim that the volume of trade received indicates that the fall and winter demand is about commencing, and look for good business from now on. The only really depressing feature is the poor outlook for the steam sizes. The market is about absorbing the production of pea, but buckwheat and smaller are still long, and are going back into stock. This is accounted for by the fact that the mines are working full time, and the market is not yet ready to absorb the entire output of these sizes. Added to this, industrial establishments using the junior sizes of coal, are in many cases working on curtailed time. The large apartment houses, however, will soon begin to start their heating systems, and it is expected that the operators will soon have no trouble in disposing of their entire output; and as the colder weather sets in, to draw on their stocks to fill the current demand.

Outside of chestnut, one hears of few concessions on the circular. It seems difficult to understand, but reports of 75 to 80c. from the circular have been heard of on this size; this is undoubtedly an exceptional case, and no doubt reflects an effort on the part of the operator to rid himself of demurrage coal.

Prices at tidewater are as follows:

	Circular	Individual
Broken	$4.75	$4.75
Egg	5.00	4.90 @ 5.00
Stove	5.00	5.10
Chestnut	5.25	4.80 @ 4.90

Bituminous—The only feature of the bituminous situation seems to be the continued demand at tidewater. Shipments to the East are heavy, compared with conditions a few weeks ago. The line trade, however, shows little or no signs of improvement.

BALTIMORE

Distinct improvement in anthracite. Bituminous market continues flat, slack still being the heavy feature. General business shows signs of awakening, but improvement is slow.

That hard coal is improving from day to day is undoubted. Steam sizes are only slightly improved but the call on the trade for domestic grades is getting much better. The late September delivery has been well up to the seasonal average for some of the dealers at least, and the householder who held off in the early spring and summer buying is now getting into the market rapidly. A larger number than usual deferred stocking this season and the prospects for October and November are quite encouraging in the domestic lines. The majority of coal men here will probably have their business on the full winter schedule by the first of November.

While the export trade in bituminous continues fairly large the general situation on soft coal is far from satisfactory. The demand for industrial fuel is far below what it should be. Except on contracts of long standing the Northwest, New England and the South are taking far less coal than was the case at this time last year. Prices are also unsatisfactory. Pennsylvania low grade coals are still offering at the mines below the dollar mark in some cases, while best Pennsylvania line fuels are quoted around $1.30 and $1.35.

The poor call from the Lakes has caused three-quarter gas in West Virginia to sell quite cheaply, and offerings around 90c. are frequent. Run-of-mine sold during the week as low as 75 and 80c., and slack was so far off color that 30 and 35c. proffers were made in some cases.

The strictly local situation is being fairly well maintained; there has been little or no surplus at tide to be sacrificed. What over-shipping took place was absorbed in the bunker trade, which has been excellent by reason of the large movement of export ships. A number of the industries here are slowly coming back into their own. The iron and cement concerns both report improvement. The rail mills of the Maryland Steel Co. resumed the past week after several weeks' suspension.

COAL CHARTERS

The "Journal of Commerce" reports the vessel situation as follows: "The steamer market was quiet in all trades, and no charters of more than ordinary interest were reported. There was a limited demand prevailing for boats in a few of the transatlantic trades, principally for grain, coal and petroleum cargoes. There are a limited number of inquiries for West India boats for single trips ,and an occasional freight offer to South America, but there is an entire absence of orders in all long voyage trades. The supply of unchartered boats available for October delivery is sufficient for the current necessities of shippers, and rates are firmly supported in all trades at about the basis of last previous charters. In the sail tonnage market a slightly increased business was done in chartering, and there is a little more demand for vessels for West India account. In all other trades the demand continues light, with rates nominal and unchanged."

Coal charters have been reported as follows:

Vessel	Nationality	From	To	Tons	Rate.
Romsdal	Norwegian	Baltimore	Havana	2028	
Teesdale	British	Norfolk	Jamaica	1560	
Riverdale	Brisish	Baltimore	Rio Janeiro	2752	$3.84
Standish Hall	British	Baltimore	Alexandria	2544	3.60
Elio	Italian	Baltimore	West Coast Italy	2208	
Sava	Italian	Norfolk	Naples	1018	
Carrie A. Lane		Philadelphia	Ponce, P. R.	703	
Brina P. Pendleton		Philadelphia	Point-a-Pitre	821	
J. Edward Drake		Philadelphia	Mayport	789	
Van Allens Boughton		Philadelphia	Boston	1909	

Note—Steamers are indicated by **bold face** type, all others being schooners.

HAMPTON ROADS

Export shipments still continue heavy with a fair amount of coal going coastwise. September establishes a new high record for tonnage. Outlook hopeful.

Dumpings still continue heavy at all piers. Export shipments for the week have gone to Naples, Campana, Piraeus, Montevideo, Palermo, Bridgetown, Cristobal, Kingston, Brindisi, Gibraltar (for orders) and Chandler (Quebec). This latter cargo consisted of about 2500 tons of nut and slack and was taken by the steamship "Thyra Menier." There was also a small cargo of run-of-mine coal loaded for San Juan, Porto Rico. One of the most interesting shipments going coastwise went into the S. S. "Lewis K. Thurlow" which took about 4200 tons. This vessel will go via the Panama Canal.

Prices on the various grades remain about the same as they have been for the past several weeks and while there are reports of sales being made above circular prices it is impossible to get these confirmed. On account of the heavy demand for prompt shipment, coal is now being taken from the storage pile of the Gulf Smokeless Coal Co. at Sewalls Point, reloaded into cars and dumped into vessels.

The outlook at this time points to September being a record month for dumpings at tidewater; the total figures should run considerably over a million and a quarter tons.

The accumulation of coal in the railway yards is perhaps somewhat less than it has been for the last two or three weeks but at the same time there is ample on hand to take care of vessels in port and any due during the next few days. Shipments are making good time from mines and with the coal accumulating there is every evidence that the shippers at Hampton Roads ports are well prepared to take care of any orders which may be offered.

LAKE MARKETS

PITTSBURGH

Market gives still poorer account of itself, no quarter showing increased demand, while Lake and manufacturing demand promise decreases. Prices very irregular.

The local coal market has continued to lose ground. Lake shipments are tapering off further, demand from retail dealers is the lightest for this date in years, railroad demand has decreased slightly, and the demand from manufacturers generally, which was showing some slight increase a week or two ago, is now tending to decrease. The steel mills are operating at not over 50% of capacity at the moment, and are receiving orders in such small volume that a rate of 40% or less is likely within a few weeks.

There is hardly any demand for free coal, and the market is not clearly established. On the limited volume of business done prices are irregular, being down to 50c. or less for slack and close to $1 for mine-run, while there is no doubt that occasional sales have been made at less than $1. Mining operations in the Pittsburgh district are at about 50% of capacity, or the smallest since April. Circular prices are purely nominal and unchanged as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.50, per ton at mine, Pittsburgh district.

TORONTO, CANADA

Warm weather and accumulated stocks have restricted the demand. Manufacturing still heavily curtailed but outlook more hopeful.

The market has latterly been very quiet, as many consumers laid in large stocks shortly after the outbreak of the war. The warm weather has also lessened the demand for domestic purposes. There is so far little improvement in the industrial situation and many factories remain closed or are working much below capacity, though conditions in this respect are gradually improving and the increased demand in some lines formerly supplied by Germany points to a speedy renewal of activity.

There are ample supplies of coal on hand and operators are making active endeavors to push sales. Prices are stationary as follows; with some shading in car lots of bituminous. Retail, anthracite, egg, stove and nut, $7.75, grate, $7.50; pea, $6.50. Bituminous steam, $5.25; screenings, $4.35; domestic lump $6, cannel, $7.50. Wholesale f.o.b. cars three-quarter lump $3.83, screenings, $2.89.

BUFFALO

No stir in bituminous and none expected in the immediate future. Slack more quiet than formerly. Anthracite selling well except egg.

Bituminous—The demand is still light. In fact there is scarcely any demand except in a modified form, as the trade is canvassed so closely that the consumer has little chance of giving out unsolicited orders. This means an exceedingly dull market till there is a revival of manufacturing.

The export demand since the war broke out has been disappointing. In fact shippers in the various Pennsylvania bituminous fields are shutting up their export offices pending a return of their former export demand.

The Canadian trade is at a low ebb. Collections there are poor and a new customer is taken on with the greatest of caution, for the seller feels that some special reason has shut the buyer off from his former supply and this was not from want of coal to fill orders. Some had Canadian business of that sort offered them lately which has added to the natural suspicion.

The prices on bituminous are practically unchanged, though slack has been hit hard on account of the warm September. Regular prices, obtained only for the best grades, remain on the basis of $2.80 for Pittsburgh lump, $2.75 for three-quarter, $2.55 for mine-run and $2.15 for slack. Allegheny Valley prices continue about 25c. lower than Pittsburgh for sizes, with slack about on a par with Pittsburgh.

Anthracite—The feature of this trade is the continued slack demand for egg. The practice of substituting stove for egg still keeps up and will do so till regulated by a readjustment of prices. The end of September has been quite different from former months. There has been no further decline to look for, so the buyer prefers to wait till another month comes in, so that his account will not come due so soon.

The Lake trade has shown more activity, shipments for the week amounting to 114,200 tons, which is a larger amount than for several weeks. Clearances were almost entirely to Chicago, Duluth and Sheboygan. There was nothing for Milwaukee or the Canadian ports of Lake Superior, as they are well supplied with both anthracite and bituminous. It does not appear likely now that the late fall will show much increase in the movement by Lake, as the amount on Upper-lake docks is large.

TOLEDO

Cold spell stimulated domestic business. Steam coal shows weakness and slack is hard to dispose of. Lake movement fair.

The cool spell helped the market but was not of sufficient duration. There seems to be a little more buying of steam coal recently but prices are not showing any greater strength. Slack is extremely hard to move and prices are the lowest known here in many years. Mine-run is said to be showing slightly more strength. The Pittsburgh No. 8 operators and miners have not yet reached an agreement and this is holding back some of the contract business.

The T. & O. C. docks have been quite active during the past week and considerable coal is going up the Lakes. Prices are holding close to the list although there are some concessions being made.

COLUMBUS

Continued weakness in the steam trade, together with a slackening in domestic demand, are the principal features of the Ohio market. Lake trade continues active. Sellers still maintain an optimistic view.

Not much improvement is reported in the coal trade in Ohio during the past week. In fact, the only change has been for the worse, as the domestic demand is now feeling the effects of the higher temperatures and orders are not coming in as rapidly. The tone of the trade is still good, and with more favorable weather, the future prospects are not believed to be particularly bad.

Dealers have had a slack demand since the weather has grown warmer, but prices on domestic grades are still stiff; in fact, there is some talk of an advance in retail prices the first of the month, but this will hardly be done under present weather conditions. Preference is still shown for the better grades.

The Lake trade is fairly good, although the tonnage handled at Toledo is not quite as large as formerly. Chartering of boats is still active and the docks of the Upper Lake ports are in good shape generally.

Steam business is slow and there are no immediate prospects of improvement. Manufacturing establishments are only buying what they need for the present. Very few steam contracts are expiring at this time. Railroad fuel contracts are mostly closed up and prices are between $1.02½ and $1.10.

Production in Ohio fields has been fairly large. In the Pomeroy Bend field, the output is estimated at normal, and in the Hocking Valley and Jackson it is about 85% of the average. The Crooksville field reports about 75%, and the same is true of Massillon. Eastern Ohio is still idle, and there are no negotiations for the adjustment of the wage agreement.

Prices in the Ohio district are:

	Hocking Valley	Pomeroy	Kanawha
Re-screened lump	$1.70	$1.75	
Inch and a quarter	1.60	1.60	$1.50
Three-quarter inch	1.45	1.45	1.45
Nut	1.15	1.50	1.15
Mine-run	1.15	1.15	1.15
Nut, pea and slack	0.30	0.35	0.30
Coarse slack	0.20	0.25	0.20

CLEVELAND

Fine coal is demoralized and coarse coals are little better. Lake trade is slow without signs of improving. Shippers are now of the opinion the season will close early.

Hocking slack that has been on the market for a week has been sold at ten cents less than the freight. Last week 100 cars of nut and slack were sold for shipment at 7½c., which in this market means $1.07½ delivered. Though quotations for shipment are nominally the same as a week ago the spot market is very weak as some coal is under car service. A good illustration of the condition of the market for Youghiogheny was an offer made by a shipper to send high grade coal to a local broker to be sold on consignment without any restrictions.

The light Lake business has curtailed operations in almost all districts shipping into Cleveland and slack is not really plentiful. With a few days of chilly weather there would be a chance of the market recovering, but a number of manufacturers are running so light and have such good supplies on hand that they are out of the market for three days to a week.

Pocahontas is in better demand owing to the large retail trade and lump and egg sizes are a little higher than a week ago. The small demand for Pocahontas slack is partially responsible for the curtailment in the production of prepared sizes, which have been less plentiful. The operators are no longer using export prospects as an excuse for refusing orders for prepared sizes.

The Lake trade has seen its best for this season. How much the shipping contracts have been reduced is manifested in the action of the owners who have been operating ships to carry contract coal. Ore shipments will end in most instances Nov. 1 and not later than Nov. 10 in almost all the others. The ship owners have decided to lay up a large number of vessels the next two weeks and will use the remainder of their fleets to fill out the coal contracts. By laying up part of the fleets they will be able to drag the ore out over a period that will let them have cargoes both ways.

Prices for current shipment are as follows:

	Pocahontas	Youghiogheny	Bergholz	Fairmount	W. Va. No. 8
Lump	$3.75				
Lump, 6 in.			$2.45		
Egg	3.75				
Egg, 6 in.			2.10		
Lump, 1¼ in.		2.40	2.25		
Lump, ¾ in.		2.30	2.10	2.00	2.05
Mine run	2.75	2.15	1.95	1.90	1.95
Slack	2.40	1.55	1.50	1.50	1.50

CINCINNATI

Demand still weak in the steam market. Price concessions are less numerous. Improvement anticipated shortly in the steam grades.

The controlling factor in the coal market in this vicinity is still the lack of any demand for steam coal. Screenings are still available in excess quantities. The call for domestic coal continues considerably behind what it should be at this time, but is excellent as compared with the steam business. Accordingly, extremely low prices for spot coal are still the rule, although perhaps fewer sales of distress coal are taking place.

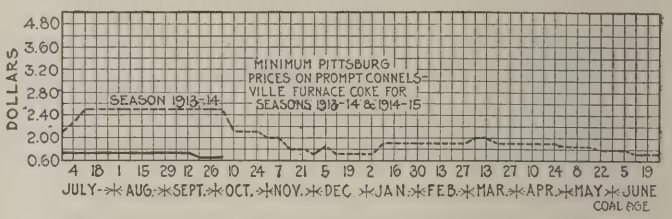
It is certain, however, that with the winter season immediately ahead, and probably most of the domestic trade yet to be supplied, screenings will continue to be a drag on the market unless the expected revival in manufacturing takes place very soon. Numerous plants are still closed down, but reports of large orders indicate that activity may soon be resumed. The refusal of consumers to accept deliveries on contracts, has been responsible for much of the cheap coal thrown on the market, complicating the difficulties of the situation materially.

DETROIT

Market almost at a complete standstill. Demand reduced to a minimum.

Bituminous—Were it not for a certain year-round trade to be supplied, business in this market would be almost at a complete standstill. The local industries are suffering severely from the restricted conditions prevailing in general manufacturing and there is no new demand for coal in any direction. In domestic coals, the Pocahontas grades are holding steady at $2.50 for egg and lump; Hocking lump of the 3-in. shaker variety is in moderately good demand at $1.70, while the ordinary domestic lump brings $1.60. Shipments to the Lakes are somewhat reduced, due to some difficulty in obtaining cars and the generally indifferent demand. Steam consumers are making practically no call whatever.

Anthracite—Anthracite is active, orders exceeding the immediate capacity of the dealers. Unconfirmed rumors are current to the effect that some dealers have advanced their retail prices 50c. per ton, beginning Oct. 1.



COKE

CONNELLSVILLE

Market absolutely stagnant, with prospects of decreased consumption. Current shipments 20% below maximum rate of the year.

The coke trade continues stagnant. No demand has developed for October, and it seems that the operating furnaces are fully covered. No furnaces are likely to go into blast while demand for iron and steel is so light that continued curtailment in output is in prospect. The Connellsville coke operators have been regulating production quite closely to demand, and very little coke has been dumped in the market. Prices are practically nominal, as follows: Prompt furnace, $1.65@1.70; contract furnace, $1.75@1.85; prompt foundry, $2.25@2.35; contract foundry, $2.35@2.50, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Sept. 19 at 243,695 tons, a decrease of 7260 tons, and shipments at 256,537 tons, an increase of 672 tons. Shipments in the past four weeks have averaged about 20% under the record rate of the year, attained about six months ago.

BUFFALO

The demand for coke is still waiting for a stir in the iron trade and a better tone to business as a whole. While regular quotations are about as formerly, some low prices for foundry are reported. The average bituminous shipper wants no coke customers, for the duller the trade the more complaints are made. Quotations continue on the basis of $4.25 for best 72-hr. Connellsville foundry and $3.30 for stock coke.

BIRMINGHAM

There is absolutely no market whatever for furnace coke, and only small lots of foundry coke are being shipped. While there is practically no demand, still the manufacturers seem to be holding to their prices.

CHICAGO

The coke market remains steady. Production has been curtailed to meet the limited demand for furnace and foundry coke.

Quotations are: Connellsville, $4.90; Wise County, $4.75; byproduct, egg, stove and nut, $4.85; gas house, $4.25.

SOUTHERN

BIRMINGHAM

Lump coal shows increase in tonnage. Local steam trade quiet, but indications point to early improvement. Pig iron dull.

Dealers are increasing their orders for lump coal, due to approaching cool weather, and this has stimulated the market to some extent. The local demand for steam coal is far from satisfactory, but the appearance in Birmingham this last week of brokers from New Orleans and Mobile indicated that there were some deals on for a large tonnage for bunker purposes. It was rumored that a large amount of steam coal would be shipped to Panama and South America during October. Pensacola brokers were also in Birmingham getting a line on the possible supply for quick shipment. A representative of the Alabama operators will visit South America this month; it is estimated that during the next six months that territory will need something like 2,500,000 tons of coal.

Production in Alabama is only fairly good, as some of the large railroads are taking the minimum on their contracts, and the local demand is not up to the average. Officials of the various railroads state that no trouble is looked for in the car supply question this fall. The pig-iron business has suffered a period of stagnation during the past two weeks, very little being sold.

LOUISVILLE

Domestic business holding steady though collections are slow. A combination of adverse conditions has created an abnormally depressed situation in the steam trade.

Future business and collections are the chief concerns of the coal operators in the Kentucky market at this time, though the volume of business, especially in domestic coals, has held up well. It is reported, however, that the retail dealers are exhibiting a tendency to slow up, and collections are poor.

The cotton situation in the South is referred to at length by the dealers and operators. The stagnation of that market

is affecting every line in the South. For instance Georgia, the largest user of commercial fertilizer of any state in the Union, is buying practically none while the railroads, already deprived of their cotton tonnage, will have no fertilizer to haul and will therefore require much less coal than in normal years. In spite of these things the coal interests are optimistic about the future. They feel that it is only a question of holding on for a while and redoubled prosperity will be bound to come. Prices continue with practically no change.

MIDDLE WESTERN

INDIANAPOLIS

Domestic grades advanced 10 to 25c. a ton, with indications of a further increase if the screenings and other steam grades do not improve. Lump moving well to railroads and householders. Mines working four days a week. Some car trouble.

Prices have been advanced 10 to 25c. a ton at the mines for domestic grades. The rise is due mostly to the low price of screenings, lump coal prices being put higher to offset this. The railroads, which now use mostly lump, are better buyers and householders generally have been getting ready for the colder weather of October. Lump coal is selling generally at $1.75. There is no set price for screenings. The mines that make a specialty of domestic coal have been running full time and the others about four days a week. With the anti-smoke laws making necessary the use of automatic stokers, industrial plants are using a larger proportion of screenings than formerly. Other steam grades are suffering in price along with slack.

Operators are now saying that if it had not been for the war upsetting industrial conditions in this country, trade in September would have been better than for many years. Retail dealers report larger buying than usual, as consumers seemed to expect an advance by the first of October. It is intimated that there may be another advance soon. Operators are feeling the first of the fall car shortage, one company totaling up a ten-day loss at its various mines the last week.

CHICAGO

Anthracite trade unusually brisk. Smokeless in steady demand, with price on mine-run strong. Hocking market firm, but only fairly active. Indiana operators advance price on domestic lump.

There is still quite a heavy demand for domestic coal in the Chicago market. The anthracite trade has been exceptionally brisk; the only size difficult to move is egg coal.

Smokeless operators have a good demand. The mine-run price for the best grades has remained firm at $1.40; the shippers of off-grades have fixed $1.25 as their minimum, and are getting $1.40 on most sales. Lump and egg coal is still scarce, the price holding firm at $2.25 the mines. The Hocking market is firm, but only fairly active on a basis of $1.60 at the mines for lump coal. The country sales at this price have been interfered with by price cutting among some of the dock companies, which have been endeavoring to move a considerable accumulation of coal.

There has been an easing up in the demand for splint coal. In the Carterville field, lump, egg and nut coal is quotable from $1.60 to $1.75. There have been some recessions in price on domestic sizes of Franklin County coal. Indiana operators have announced an advance on domestic lump coal to $1.75.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.47	$2.65@2.80	$2.42@2.52	
Steam lump	2.02		1.97	
Egg		2.65@2.80		4.05@4.30
Mine run	1.87	2.15@2.25	1.87	$3.30@3.45
Screenings	1.07@1.12	1.40@1.50	1.07@1.12	

Harrisburg quotations are: Domestic lump and egg, $2.65@2.80; steam lump, $2.15@2.20; mine-run, $2.15@2.25; screenings, $1.40@1.50; No. 1 nut, $2.80; No. 2 nut, $2.30@2.40.

Carterville prices are: Lump and egg, $2.65@2.80; No. 1 washed, $2.80; No. 2 washed, $2.30@2.40.

ST. LOUIS

Domestic grades heavily oversold and production continues below requirements, due to light steam demand. Steam market still demoralized. Standard domestic coals not showing their customary form this season.

There is little change in the local market, with the exception, perhaps, that the steam grades are a trifle easier. Operators all report that they are far oversold on the larger sizes of coal, and in order to avoid having orders pushed on them, they are asking as high as $1.85 to $2 for lump and egg; $1.75 is about the top of the market, but there are indications of a further increase soon unless the steam market picks up. This is not likely to occur in the high-grade fields on account of the deplorable condition existing in the inner district.

The high-grade washed market picked up considerable during the past week, especially on the larger sizes, Nos. 1 and 2 moving quite freely. Screenings fell off to 20c. and were hard to move at that figure. The top of the Standard 2-in. lump market seems to be about $1.15, although some operators have been able to get $1.20. Offsetting this, they are giving their screenings away for the freight charges; 3x6 egg coal is selling for $1, and nut coal all the way from 35 to 75c. The domestic demand for Standard coal seems lighter this year, due principally to the fact that Carterville and Franklin County coals seem to be getting a better foothold.

In the high-grade market, lump and egg will be in good demand at from $1.65 up, with tendency to go to $1.85 the early part of October.

Pennsylvania anthracite is moving in in good tonnage, and the demand seems to be good. Smokeless is a drug on the market, and there are no buyers at any price.

The prevailing circular is:

	Williamson and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	.....	....	$1.30	$1.10@1.20	$1.20
3-in. lump	.....	....	1.40	.....	.....
6-in. lump	$1.75@1.85	....	1.50	1.25@1.35	1.40
Lump and egg	1.85@2.15	$2.25	.....	.....	1.15
No. 1 nut	1.45@1.50	....	.....	0.75@0.80	.....
Screenings	0.70@0.75	....	0.80@0.85	0.05	0.10
Mine-run	1.05@1.10	....	.....	0.75@0.80	.....
No. 1 washed nut	1.50@1.65	2.25	1.50	....	.....
No. 2 washed nut	1.35@1.40	....	1.35	....	.....
No. 3 washed nut	1.10@1.15	....	.....	....	.....
No. 4 washed nut	1.00@1.05	....	.....	....	.....
No. 5 washed nut	1.20@1.25	....	.....	....	.....

Retail prices, delivered, are: Lump and egg, Carterville, $3.50; Mt. Olive, $3; Standard, $2.75; smokeless, $6.25@6.50. Anthracite, chestnut, $8.50; egg and stove, $8.25; grate, $6.25@6.50.

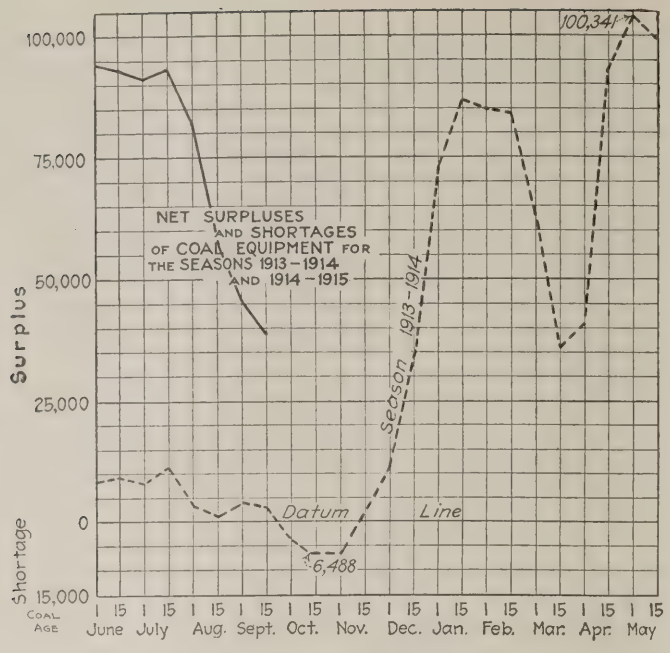
KANSAS CITY

No change in prices and little improvement in the movement. Trade very unsettled. Circulars scheduled for an advance soon.

Kansas City is not laying in heavy supplies of coal for the winter, and yet retailers declare that coal will be consumed in as large quantities as ever, the bulk of the buying coming later. There has not been a real touch of winter yet. And the fact that the Kansas natural gas receivers are holding out prospects of much gas this year, is a factor in the situation. On the other hand, the prospect that steam plants may not get fuel oil possibly will offset any advantage gas consumers will have. Some of the large buildings which buy heat depend upon natural gas for running their own plants early in the season before gas gets low. The wholesalers in heat started up their plants at fall schedule last week.

Through Kansas, but not in Kansas City, there are notices being issued by retailers that coal prices will advance Oct. 1. In Kansas City there are no threats of increases, but dealers believe that coal will probably rise by Nov. 1.

PRODUCTION AND TRANSPORTATION STATISTICS



THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Sept. 15, as follows:

	Surplus	Shortage	Net*
New England Lines	1,326	0	**1,326**
N. Y.; New Jersey, Del.; Maryland; Eastern Penn.	5,232	0	**5,232**

FOREIGN MARKETS

GREAT BRITAIN

Sept. 18—Outside of the navy requirements, business is very limited on account of difficulty on the part of foreign buyers of arranging cash. On this account, and in spite of the diminution in output, free coal is more plentiful than it has been for some weeks, and prices are inclined to be weaker. Quotations are approximately as follows:

Best Welsh steam	$5.04@5.28	Best Mountmouthshires	$4.26@4.32
Best seconds	4.56@4.86	Seconds	4.08@4.20
Seconds	4.26@4.38	Best Cardiff small	1 68@1.74
Best dry coals	4.38@4.62	Seconds	0.96@1.44

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both net, exclusive of wharfage, and for cash before shipment or against invoice.

Freights—Tonnage is offering freely, but orders are scarce. Rates are approximately as follows:

Gibraltar	$1.68	Aden	$2 16
Malta	1.68	Colombo	2.22
Marseilles	1.64	Sabang	2.22
Algiers	1.44	Singapore	2.40
Genoa, Savona	1.56	Las Palmas	1.80
Naples	1.68	St. Vincent	1.92
Venice, Ancona	1.86	Rio Janeiro	3.36
Alexandria	1.86	Monte Video	3.12
Port Said	1.80	Buenos Ayres	3.36

Operations in the coal industry are still restricted in some measure by the shortage of empty wagons, the reduced supply of skilled labor, the limitation of the exports and other factors in the situation which have had to be taken into account since the outbreak of war. The returns regarding employment at the mines cannot be regarded as unsatisfactory, the Board of Trade stating that while a considerable number of collieries are working only four or five days a week, there is considerable pressure in the steam coal trade in South Wales, where more men could be employed if they were available. Many pits have worked less than four days a week recently.

In the Newcastle district, there has been little change of importance in the state of the coal market. Business continues dull in all departments, but the shipments show some slight expansion, and there are signs that the inquiry is growing.

In the Yorkshire district, trade is fairly brisk. The inquiry for large steams on export account is good, and, when facilities permit, a more active state of affairs is expected. Some collieries have benefited by government contracts for steam coal, more of which may follow.

In the Midlands, the house coal position is quieter now that collieries have dealt with the rush of house coal orders experienced at the beginning of the month. There is no speculative buying going on, merchants just ordering for their immediate requirements.

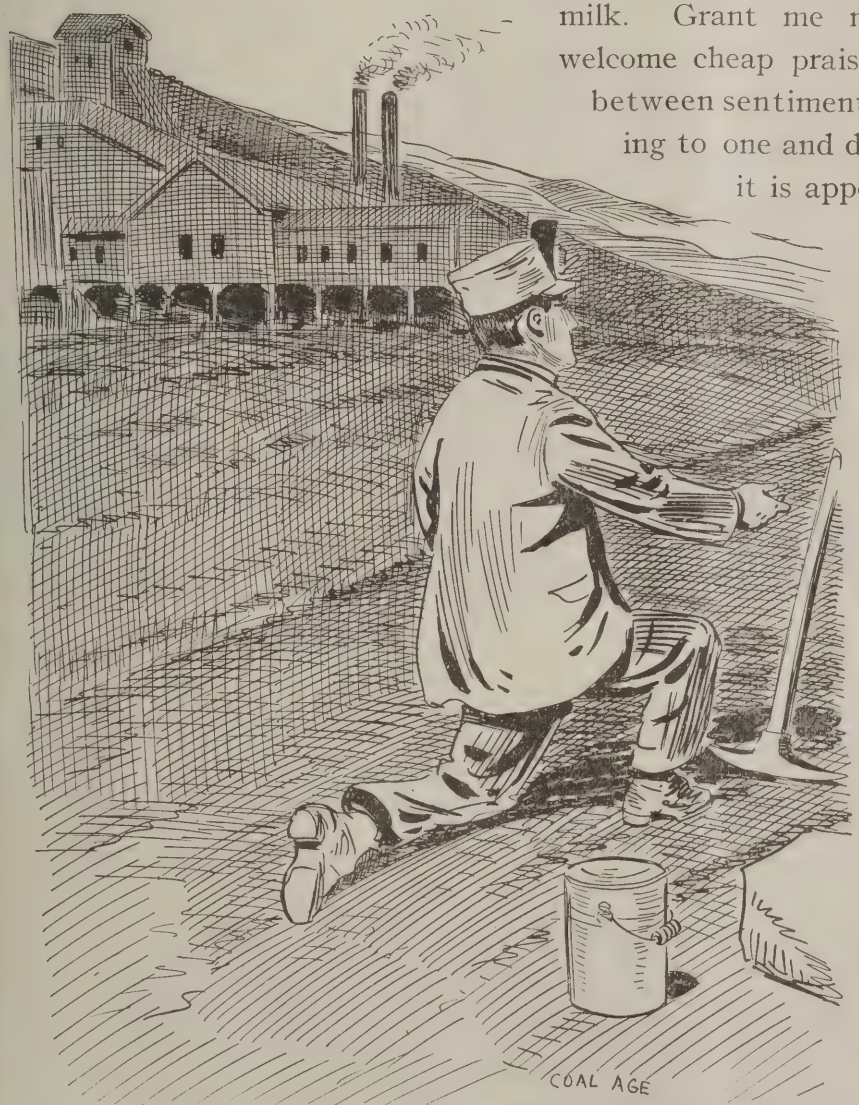
In Lancashire, the fuel market is quiet but steady, and prices are held fairly well, but the uncertainty about credit is hindering sales. Many of the mills are idle, and consumption is still restricted.

In South Wales, there has been but a limited inquiry for all descriptions of steams. Shipments on Admiralty account and for foreign governments are slackening, leaving more coal of all qualities on the market, and more easiness prevails, especially for the second and cheaper qualities.

Rarely has the wholesale market for railborne house coal been so dull and lifeless as it is at the present time. Notwithstanding the somewhat lower temperatures generally and the colder nights and mornings in particular, the retail trade remains exceedingly quiet. The railway congestion due to military requirements has been relieved in some measure during the past week or more, with the result that many collieries are getting a better supply of empty wagons and are working with less irregularity. There can be no doubt, at any rate, that there are now ample supplies upon the London market.

No change has occurred in retail prices as yet, although an advance is now much overdue. The War Office has taken over a very considerable number of the horses employed in the coal trade, and may have to take over more to make good the wastage of war, which will probably be very serious. There are a few motor lorries here and there, but they are only suitable for special work, and it is quite certain that in these times of stress there will be a limit to the available supply of horses.

The seaborne trade remains quiet. Since the previous Friday, 33 colliers had passed up the river.—"The Iron and Coal Trade Review."



COAL AGE

Vol. 6 NEW YORK, OCTOBER 10, 1914 No. 15

The Good Miner's Prayer

OH POWERS that Be! make me sufficient to mine own occasions. Teach me to know and to observe the Rules of the Game. Give to me to mind mine own business at all times and to lose no good opportunity of holding my tongue. Help me not to cry for the moon, or over spilled milk. Grant me neither to proffer nor to welcome cheap praise; to distinguish sharply between sentiment and sentimentality, cleaving to one and despising the other. When it is appointed for me to suffer, let me—so far as is humanely possible — take example from the dear well-bred beasts, and go away quietly, to bear my sufferings by myself. Give to me to be always a good comrade, and to view the passing show with an eye constantly growing keener, a charity broadening and deepening day by day. Help me to win, if I may, but — and this, OH POWERS! especially—if I may not win, make me a good loser.

Amen.

Apologies to the Good Indian's Prayer, Anon.

Storage-Battery Locomotives at the Grant Mine

By R. Dawson Hall

SYNOPSIS—At the mine of the Grant Coal Mining Co., storage-battery locomotives are doing all the gathering work. The superintendent states that each locomotive can, and most do, handle 375 tons per day without difficulty. The average haul is 15 to 16 miles per day.

The storage-battery locomotive has been at once the hope and the query of the mine operator. He has felt on the one hand that it could be made more effective than the mule and so save the employment of men. It also could be constructed to need less traveling room than mules, and, therefore, save brushing. Moreover, it needs no conductors, and hence saves much expense in the erection of wiring, bonding of rails and maintenance of both. Where the roof is bad, the cost of maintenance of trolley wires is no small item and the danger of falling wires causing fires, and perhaps explosions also, is not to be overlooked. Furthermore, even with low-tension currents there is a certain risk in the use of trolley locomotives.

On the other hand, the operator has been wondering if storage locomotives were really reliable, whether they would be more seriously wrecked than trolley locomotives in a collision or derailment, whether in view of their cost they would really be economical, because a costly unit must haul more coal than one which is cheaper if its use is to be justified. In fact, the operator is disposed to believe that a storage-battery locomotive might well prove its value where the grades were adverse, because its drawbar pull being greater than that of a mule, it could pull a longer trip in cases where with mules the capacity of each unit is all too small. But the same operator has been wondering whether the storage-battery locomotive will pay on a level or on a favorable grade.

Storage-Battery Locomotives Are Proving Desirable

It is interesting to note that all these points of question and doubt do not appeal to H. M. Stewart, the general manager of the Grant Coal Mining Co., of Terre Haute, Ind. Very coldly, for there is little enthusiasm with him, he stated that he had now six storage-battery locomotives, which he had acquired at first one by one and then by twos. He added that he was about to buy two more like those he had already purchased, and he stated that the locomotives would gather 375 tons per day of 8 hr., doing as he estimated it, the work of four or five mules.

Plant of the Grant Coal Mining Co., at New Goschen, Ind.

Of course, some management is required to prevent interference between storage-battery locomotives, though not so much as between smaller units like mules. Furthermore, care must be taken to save long runs in gathering and to prevent the combining of two or more remote districts in the delimiting of territory to be served by a single locomotive. The problems are not different from those relating to mules, where storage-battery locomotives are involved; but to get record runs favorable conditions must,

Storage-Battery Locomotive Pulling Cars Out of Room Neck into a Room Entry

Locomotive Running on Lower Flange of Rail, Track Not Needing Bonds May Be of Impermanent Character

of course, as everywhere, be provided. Perhaps a few notes about the Grant mine may serve to explain conditions.

The Grant Colliery

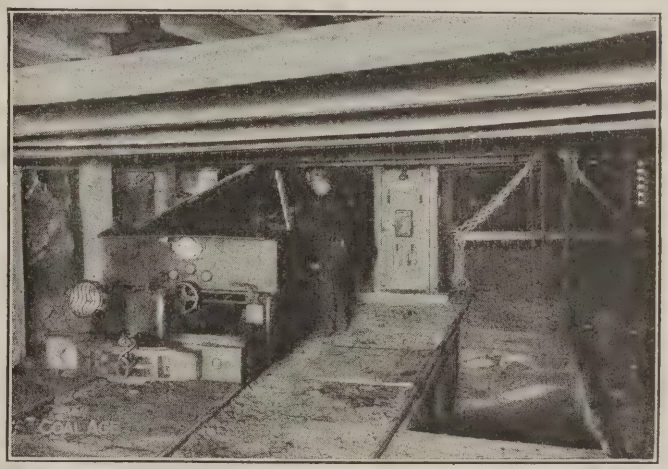
The shaft is 272 ft. deep and is sunk in a country which is comparatively flat. The seam worked is No. 5. That and No. 4 are the two seams most generally operated in the Indiana "bituminous-coal" district. (The custom seems to be to class the "block" coal by itself, though, of course, it is as bituminous as the other.) The coal measures from 4 ft. 8 in. to 5 ft., the average being about 4 ft. 10 in.

The illustration will show that the mine is in most details strictly uptodate. The shaft is concreted; the headframe designed by Allen and Garcia is of steel, stiffened in places with concrete. The rough finish on the power house, it is true, shows the lines of the forms and gives the impression of wood, but that is deceiving, as the walls are concreted.

The bottom and workings were laid out by Rush and Everson, engineers of Terre Haute, Ind., and as a result of careful planning, three men on the bottom handle 1700 to 1800 tons per day. There is a Holmes lift for empty cars, and the caging is done by Bowerston automatic caging machines.

Methods of Working in Indiana

Indiana is a strong Union state, and the agreements with the Union have made it hard to operate the mines of Indiana with anything like due regard for conservation and even of safety. This is no place to discuss whether the burden of proper methods of mining should fall on operator or miner, and it is only necessary here to state that the rooms are from 21 to 24 ft. wide and the pillars 9 ft.



Shaft Bottom at Grant Mine

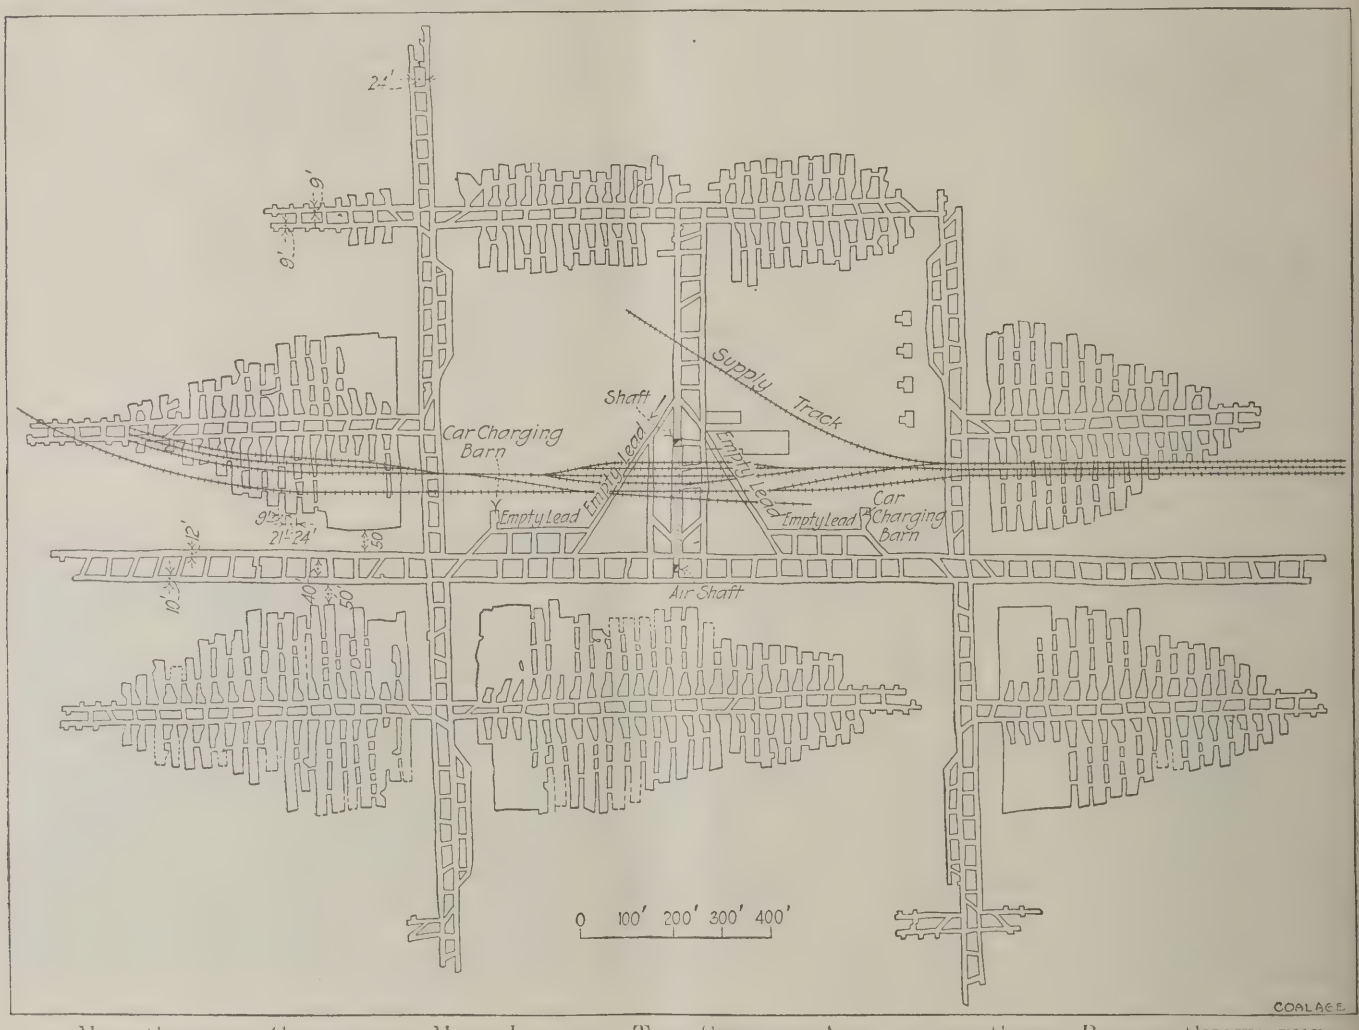
There have not been wanting those who wonder why the Indiana roof is so troublesome and so ready to squeeze, and that several men have been endangered by sudden movements of the roof, but the reason is so obvious that one forebears to point it out. With such weak room pillars and with chain pillars only 24 ft. wide in the headings, and rooms widened from quite close to the entry, what else could be anticipated? Yet we think that in choosing the Grant mine, we have chosen one of the most favorable illustrations of Indiana practice, for more than usual care is shown in all details of the plant.

A New Method of Working

Yet, if a digression may be pardoned, there is an exhibit of a sense of the importance of good pillars at the mines

The Car Barn with Chain Hoists for Removing Batteries

of the Bunsen Coal Co., Universal, Ind., where the room centers are 66 ft. apart, and the rooms being 21 ft. wide, the pillars are 45 ft. thick. The crosscuts, it is true, between rooms are for the most part 18 ft. wide and to comply with the somewhat too drastic law, are only 45 ft. apart. This width of break-through is adopted to avoid payment for driving a narrow place. Every 200 ft. the crosscuts are made narrower, only 12 ft. wide, and are driven by sights, and all the rooms are also so driven.



These crosscuts being opposite continuously from room to room, serve as counters, such as are driven in the anthracite region. The coal is hauled out by these to the cross entries, and the parts of the rooms thus cut off are abandoned till the time for drawing pillars arrives. The rooms are thus driven on till the boundary is reached.

So far no pillars have been recovered. That work, however, should not be difficult, as the first mining has been so conservative. However, the roof gives quite a little trouble when it gets damp, and this may cause some trouble if damp air is allowed to circulate through the parts of the rooms which are thus temporarily abandoned.

There is no reason to believe that the problem of the main roof in Indiana is any worse than that elsewhere. It would be solved at once if the idea that adequate support is needed, were boldly faced. It was interesting and pleasing to be told by a superintendent that chain pillars are almost worthless, and that flanking pillars the 43-in. height of the storage-battery locomotive gives it an advantage over the mule, though sometimes where a slight sag makes it necessary to boost the track, the height becomes somewhat scant, for though the coal is always 13 in. thicker than the locomotive is high, there is an allowance to be made for rail and tie.

Haulage at Grant Mine

The main haulage of the Grant mine is by two trolley locomotives, one a 7½-ton Goodman, and one a 10-ton Westinghouse. These pull from the double partings in the cross-entries and deliver their coal at the shaft bottom.

Map, Showing Convenient Mine Layout. The Stippled Area at the Shaft Bottom Shows the Concreted Section

could alone save an entry. Such a statement should be a platitude which everyone should believe, but you could count the people who adhere to it and practice it on the digits of your two hands.

The Drawslate Conditions Are Bad

The roof in Indiana seems to be of a character that makes the use of moistened air prohibitive. In one mine the reversal of the current is alleged to have done much to reduce falls, and it is the annoyance, cost and danger of falling trolley wires, which is, in part, making the trolleyless locomotive look so desirable in the State of Indiana.

The bottom at many of the mines is quite hard, and it is impossible to make height by shooting. Consequently,

The gathering locomotives draw from the faces of the rooms. They go into one room entry and find all the cars loaded. They draw these and go into the same entry with empties. They leave these at the mouths of the rooms and then go into another entry and draw loads there.

The power by which the trolley locomotives are propelled and the storage-battery locomotives charged is provided by one 100-kw. Goodman Manufacturing Co. electric generator, running at 250 r.p.m. and generating 364 amp. at 250 to 275 volts pressure. This is driven by a McEwen engine 16x16 in., with a rated capacity of 137 hp.

The boilers are five hand-fired Terre Haute Boiler Works units, producing 750 hp., using good run-of-mine coal. Here, perhaps, is the *one* point where the plant is

not uptodate. The headings are driven by puncher machines, and the compressed air for this work is provided by two Ingersoll-Rand compressors. The machine shop is unusually well equipped, there being a hammer, emery wheel, planer, hack saw and two drill presses, all power-driven.

The Storage-Battery Locomotives

A storage-battery locomotive was first installed in May, 1913. In September of the same year, another was added, in November two more were purchased, and in July of this year yet another two, and it is said two more are to be ordered. The locomotives have needed little or no repairs. Derailments and collisions—the first not infrequent—do the locomotives no greater harm than if they were propelled by trolley.

The locomotives pull from 12 to 14 trips per day, bringing on each occasion 12 to 18 cars. The net load on these cars runs from 3500 to 4000 lb. per car, and the wagon itself weighs about 1600 lb.

The locomotives weigh 5 tons, of which 1900 lb. is due to the weight of the battery, which consists of 63 cells. When these are charged, they have a capacity of 300 ampere-hours. The track gage is 42 in. The cells used are made by the Edison Storage Battery Co., of Orange, N. J., and the locomotives are manufactured by the Jeffrey Mfg. Co., of Columbus, Ohio.

With the storage battery jogging along unflaggingly over the rails at 5 or 6 miles per hour, and pulling any load likely to be placed behind it, it is really largely a matter of management whether the locomotive does as many times as much as a mule to justify its use. The storage-battery cells, whether Exide or Edison, appear to be giving satisfaction, giving both reliability and the power desired. They are built to withstand overloading, overdischarging and mechanical violence. There will be a further reference to these locomotives in an early issue.

Handling Tonnage Bulletins for Machine Mines

By H. H. Warner*

Various systems have been used to handle machine tonnage, both on the mine bulletin or tipple sheet and on the payroll, but one that eliminates unnecessary office detail is set forth herewith:

In starting this system, use check numbers from one to as high as necessary to accommodate the operation of the mine in question, and as these check numbers are issued, enter on the bulletin above the check number the number of the machine the loader is to work after, i.e., issue check numbers just the same as if it were a solid operating mine, with the exception that the machine number is entered above the check number.

The weighmaster in this case posts his tonnage as it arrives in the regular way and at the close of the day's business, he adds through his bulletin beginning with machine No. 1 and summing up their tonnage, machine No. 2, No. 3, etc., and as the final check against his separate machine addition, he makes complete addition of his bulletin beginning at check No. 1. He posts on his bulletin a recap of the machine tonnage from his machine addition, so that the office can post the machine tonnage to the machine runners without having to make another addition.

*Chicago, Ill.

In case a loader is changed from one territory to another, or from one machine to another, he places upon the first car loaded from the new territory a machine number, together with his check number. For instance, if check No. 36 was loading according to the present bulletin on machine No. 1, that number would be posted above check No. 36 on the bulletin. If he was transferred to machine No. 5, at any time, the first car he loaded from this territory would bear a No. 5 machine number and when this car reached the weighmaster, he would enter No. 5 after the last car received from No. 1 territory and the loader's tonnage from that time on would be posted to No. 5 machine. It is a very good idea to use either red or blue pencil in placing the machine numbers over the loading-check numbers, as it helps considerably in adding the separate machine tonnage.

When this bulletin reaches the office to be posted to the payroll, the payroll clerk begins at check No. 1 and posts straight through his payroll and the grand total of all the payroll loaders' tonnage should equal the grand total of the bulletin. When posting the machine tonnage, it will be necessary for him to split this tonnage as shown by the weighmaster between the runners on the various machine territories, for instance, No. 1 machine is double shift, four men working on same, the tonnage shown on the bulletin for No. 1 machine will be split by four and the separate amounts posted to the credit of each runner's account.

Where solid coal is loaded with machine coal, the letter "S" is placed on the bulletin above the loading-check number instead of machine number. This tonnage is carried the same as machine tonnage on the recap of daily bulletin.

This system is superior to the system where the first fifteen numbers on the bulletin are for No. 1 machine, the next fifteen for No. 2, etc., as it eliminates the necessity of changing the loaders' check number at the time he may be changed to a different territory.

To demonstrate, loader No. 5 is loading on No. 1 machine and during the day receives notice from the mine manager to change his working place and begin loading after No. 4 machine. With the last mentioned system, it would be necessary for him to come on top, get in touch with the office and have his loading check changed to some check number that was vacant on No. 4 machine before he could resume his work. Furthermore, when this change is made the fellow is carried on the payroll as having worked on No. 1 machine. Later, he may be given still another number on the payroll, and there are quite a few times when this becomes very confusing to the office in posting the loader's supplies, union dues and assessments.

Invariably when the pay is closed the payroll clerk will wind up on pay day with two or three different pay envelopes for the same man. The system outlined above eliminates any changes in the office work relative to the pay of any particular loader, and he retains the same check number and is carried on the payroll in the same place at all times.

The weighmaster takes care of the details outlined and carries a semi-monthly pay bulletin both for machine runners and loaders. This bulletin is posted each and every day for inspection, and by doing this, there is no question as to the correctness of the tonnage carried on the payroll for each individual. Any differences that come up before the pay is closed are handled through the weighmaster for correction.

The Purchase of Coal on Specifications--III

By F. R. Wadleigh*

SYNOPSIS—This third installment takes up in detail a study of the effects of sulphur on the actual value of the coal to the consumer. The importance of designating specific sizes is also shown. Two samples of typical specifications are given, one being for the standard proximate method, now so commonly used, and the second a more exhaustive and comprehensive type.

Perhaps one of the most glaring inconsistencies in many specifications now in use is the attempted regulation of the amount of sulphur in the coal, with the infliction of absurd and unfair penalties for a small increase above the standard. In the first place, the coal operator or seller cannot control the amount of sulphur in his coal.

Professor Lewes states that the original source of sulphur in coal is probably calcium sulphate, which exists in the ashes of vegetation and remains in the coal ash. Under the influence of temperature, pressure and heat in the presence of carbonaceous matter, the sulphate becomes reduced to sulphide, which combines with the iron salts and forms sulphide and disulphide of iron (iron pyrites).

Sulphur is present in coal in several forms, as a sulphate of lime, (gypsum) pyrites (rarely as marcasite) and as organic sulphur, the latter in compounds about which little or nothing is known, where the sulphur is combined with carbon and hydrogen; the organic sulphur varies in different coals from 2 to 75 per cent. of the total sulphur. (Lewes, "Carbonization of Coal.")

Of these various forms of sulphur, only the amount of iron pyrites can in any way be regulated by the coal operator and that to a limited extent only. The gypsum comes in thin layers or scales along the cleavage planes of the coal and cannot be removed in mining.

The organic and free sulphur cannot, of course, be removed but at any rate it is all driven off when coal is burned. The iron pyrites comes in balls and lenses, or layers and small scales, distributed throughout the coal; much of this can be removed at the mines by washing unless it is in small scales.

Effect of Sulphur in the Boiler Plant

Sulphur has a heating value of from 4050 to 5300 B.t.u., depending upon its form, whether organic or iron pyrites. Dioxide of sulphur with water forms sulphurous acid which may corrode any metal it comes in contact with, but this action only takes place after cooling of the gases of combustion. The action of sulphur in pitting or corroding boiler surfaces has been greatly exaggerated and may be practicaly neglected. The same applies to its action on grate bars, except in rare instances.

The percentage of sulphur in coal is no indication of its tendency to form clinkers. This is clearly proved by the tables given in the preceding installment†, showing the ash fusing temperatures with amount of sulphur, for various coals. There is no relation between the percentage of total sulphur in the coal and either the amount and kind of clinker or the ash fushing temperature.

Sulphur and Spontaneous Combustion—Fires in coal piles or bins from spontaneous combustion, are believed by many users to be due to sulphur in the coal. The theory that spontaneous combustion of coal may be caused by the oxidation of iron pyrites or sulphur has been held for a number of years, regardless of the fact that coals with less than one per cent. sulphur are known to be extremely liable to spontaneous combustion. As long ago as 1864, Dr. Percy pointed out that pyrites has little to do with spontaneous combustion, a fact later confirmed by Dr. Richter.

The U. S. Bureau of Mines, in Technical Paper No. 16, states that sulphur has only a minor effect on spontaneous combustion, in most instances. Numerous samples of coal taken from the hottest parts of a burning pile or bin showed that in no case was the unoxidized sulphur less than 75 per cent. of the average original total sulphur in the coal. The two great English authorities on this subject, Professor Lewes and Dr. Harger, both state positively that sulphur can have little to do with originating spontaneous combustion.

Therefore, no specifications for steam coal should include the sulphur content as a basis for payment. The U. S. Government specifications have no sulphur limit or percentage, except in the general description of coal, but there are a number of other specifications now in use that penalize the seller for a variation of ¼ of 1 per cent. Even if sulphur has anything to do with clinkering and thus increasing the cost of plant operation, such a small increase could not possibly be measured.

No specifications in use, in this country, so far as I know, take into account the size of the coal, in the way of specifying a percentage of small coal, dust, or slack and penalizing or giving a bonus on such basis. It is true that some contracts require the absence of "dust," but only in a general way is such requirement mentioned.

In other countries, this item is made of considerable importance in all specification contracts. This difference in practice is largely due to the fact that a great part of the steam coal used in this country is run-of-mine, while abroad it is nearly all sized by screening.

Type of Contract without Specifications

Should there not be a standard for run-of-mine coals used in this country as regards percentage of lump and slack? We know that the size of coal has an important effect in combustion results, a fact that is given much more weight abroad than here. As an example of this, see for instance, the specifications for the purchase of coal for electrical works as agreed on between the large London coal contractors and the Associated Municipal Engineers, which will be given in a succeeding article.

The old method of coal purchase, by name or reputation, still the most largely used, can and does give good results. A standard contract of this kind on which mil-

.....

Terms of payment, cash on or before the 12th of each month for all coal shipped during the preceding month. Bills subject to sight-draft if not paid when due.

Every effort will be made for the fulfilment of this contract, but the sellers will not be responsible for same during any war affecting it, or if prevented by strikes, or combination of miners, laborers or boatmen, accidents at the mines, or interruption or shortage of transportation or navigation, by any cause or any occurrence. In such case the obligation to deliver coal under this contract is canceled to an extent corresponding to the duration of such cause, occurrence, interruption or shortage, and no liability shall be incurred by the sellers for damages resulting therefrom.

.....Railway Company's scale weights at point of shipment are accepted as conclusive.

Another kind of specification is that which gives: A standard analysis and limit of constituents; provisions for sampling each shipment of some certain size; scale for penalizing inferior coal.

No analysis is made unless coal gives inferior results in actual use, in which case the sample of that particular shipment is to be analyzed and payment based on results of such analysis according to scale of penalties. If the analysis shows coal to be within the standard limits given, then no penalty is to be affixed and the inferior combustion results are assumed to be due to poor handling or condition of equipment. The following is a typical example of such a specification:

SPECIFICATIONS AND CONTRACT FOR FURNISHING ——TONS OF BITUMINOUS COAL

By and between The.....a Corporation of the State of Pennsylvania, hereinafter called the consumer.

This contract shall cover the full requirements of the .....Co., for a term of.....from .....to.....

Description of Coal to be Delivered

Run-of-mine semi-bituminous coal, having an analysis approximately as follows, which analysis shall be taken as the standard for all coal delivered under this contract:

Moisture	2.5
Volatile not to exceed (dry coal)	18.00
Fixed Carbon	72.00
Ash not to exceed (dry coal)	8.00
Sulphur (dry coal)	1.5
B.t.u. (dry coal)	14,300

Ash fusing temperature, not lower than 2500° F.

Commercial name of coal.....

Name of mine or mines.....

Location of mine or mines.....

Name of coal bed or seam.....

The coal to be furnished under this contract is to be delivered by the contractor on cars at the plant of the..... at....., and is to be of the grade and kind described in the specifications.

It is understood and agreed that the Company will deliver under this contract as much coal of a size not to exceed 4 in., that is, coal that will pass through a 4-in. perforated screen, as it may desire, in quantity not to exceed the total tonnage called for by this contract; such 4-in. coal is to come from the same mines and to have the same approximate analysis as the run-of-mine coal described herein.

Deliveries

Coal shall be delivered at the rate of.....tons per week until the whole quantity has been delivered.

All deliveries to begin within ten (10) days after the signing of this contract.

It is understood by and between the parties hereto that the intent and purpose of this contract and of these specifications is to obtain for the consumer, during the life of this contract, a continuous supply of fuel, constant as to quality and delivered as the needs of the consumer require.

It is agreed that the failure on the part of the company to furnish coal of the quality described in this proposal on three consecutive deliveries, or in case more than 20 per cent. of the coal up to any date during the life of the contract has been of a quality below the standard and subject to rejection under this contract, this contract may, at the option of the company, be terminated.

It is agreed that, if for any reason, the Contractor fails to deliver coal in accordance with the terms of this contract, the company may buy coal in the open market and charge against the contractor any excess in the price of the coal so purchased over the contract price, or, at its option, the company may cancel the contract.

Causes for Rejection

It is understood and agreed that this contract shall not be binding if at the end of a service of ten days duration, the coal fails to give satisfactory results because of excessive clinkering, when burned in a hand fired furnace, at a rate not to exceed 25 pounds of coal per square foot of grate surface per hour.

Each car of coal delivered will be sampled by a representative of the.....Co., at their option.

(The method of sampling to be used is here specified).

If the coal from any car gives unsatisfactory results in actual use under boilers, the samples taken from such car, at the option of the consumer, shall be sent to..... for analysis.

Should any analysis show that the coal was inferior to that called for by the standard analysis given in this contract, than a reduction in price per ton shall be made on the coal contained in the car from which the sample was taken.

It is understood that the analysis of any sample is not to be used to regulate the price from month to month, but only where inferior coal has been delivered and in such cases the amount of reduction shall be determined by such analysis.

Basis for Reduction from Price on Account of Inferior Coal as Shown by Analysis

Ash. (Standard 8%)

Per Cent.	Deduction per ton (cents)
8.01 to 9.00	2
9.01 to 10.00	4
10.01 to 11.00	7
11.01 to 12.00	13

B.t.u. (Standard 14,000, dry coal)

Variation of 50 B.t.u. correction in price will be determined by the following formula:

$$\frac{\text{delivered B.t.u.}}{\text{standard B.t.u.}} - \times \text{standard price} = \text{price resulting from B.t.u. correction}$$

Degrees F.	Deduction (cents)
2499-2450	1
2499-2350	2
2399-2350	4
2349-2300	8
2299-2250	15
2249-2200	25
2199-2150	40

The company agrees to use the utmost diligence to keep the consumer fully supplied with the quality and quantity of coal specified during the life of this contract, it being understood that sufficiency of supply and quality of coal are of the utmost importance to the Consumer.

The company shall not be liable under this contract for failure to deliver or for any delay in delivering said coal if he is prevented from or delayed in doing so by strikes or combinations of miners or laborers occurring at the mines of the.....or upon any railroad over which the coal must of necessity be transported to reach its destination, or in case he is prevented or delayed by delays in transportation, or by other causes wholly beyond his control.

In case the output of the said mines is reduced by reason of any said causes but not wholly prevented, then the Consumer shall be entitled to receive under this contract the same proportion of the coal so mined as the total amount of coal required to be delivered under this contract bears to the total amount of the coal that the Contractor is required to deliver all the coal required to be delivered hereunder, he agrees to use his best endeavors to keep th Company supplied with coal of good quality at such prices as may be reasonable under the circumstances.

The Consumer shall have the privilege of testing other

coals to an amount not exceeding ten per cent. of the total tonnage to be delivered under this contract.

The undersigned hereby agree to deliver the coal as described in tons of 2240 lb. in quantity as previously specified and in strict accordance with these specifications.

Weights

All payments shall be based on railroad weights.

Payments

Payments for the coal delivered will be made at the price specified in this contract, less any deductions for inferior coal as elsewhere specified. Such payments for the coal delivered under this contract shall be made on the..... day of the month following that on which coal is delivered on the Consumer's tracks.

In 1908, the American Society for Testing Materials took up the question, with a view of putting out standard specifications for all classes of coal and for different uses, steam making, gas manufacture, metallurgical work, etc., and appointed a committee of about 50 members, divided into nine sub-committees, to frame suitable specifications. This committee was made up of leading representatives of the mine operators, of the consumers and of chemists and engineers.

For various reasons, this committee has not as yet agreed upon any standard specifications, partly because it was recognized that the whole subject was a large and growing one, that changes in methods of analysis, greater knowledge of coals and their sampling, alternations in plant equipment and operation, all made it advisable to postpone final action for a time. Differences of opinion as to what items should be embodied in the specifications added to the difficulty. The following quotation is from their preliminary report, presented to the Society at its annual meeting in June, 1910.

The committee recognizes the growing interest in the general subject of the purchase of materials under specifications; and it is believed that in all cases where a rational basis for such specifications can be agreed upon the results of such practice must be beneficial to both producer and consumer, as it enables the consumer to point out more specifically just what he wants while the producer can bid in a more intelligent manner; in addition it facilitates more suitable settlements.

Your committee desires to emphasize certain reforms which are regarded as fundamental accompaniments or outgrowths of the present movement for specifications, and which are essential to the welfare of the coal industry in the United States, namely:

(1) A classification of coals with respect to fuel efficiency, the adaptation of equipment to coals for obtaining the greatest efficiency from the different varieties, the continued use at each plant of that type of fuel best adapted to the equipment, the use of the low-grade fuels either at the mines or within short distances, and the use of the high-grade fuels under conditions demanding highest efficiency and requiring distant transportation.

(2) Special efforts on the part of architects and engineers to provide adequate space for power and heating plants and proper equipment, with a view of making the most efficient use of the fuels that are most available.

(3) Such readjustment in the prices at the mines of the different classes of coals as will render possible clean and safe mining, and the use at local or distant points of all grades of coal worthy of being placed on the fuel list.

Settling Sump for Mine Pumps

By Thomas G. Fear*

Cleaning the sump in a mine is anything but a pleasant job, as all who are familiar with mining operations know. To the mine owner, furthermore, it usually means an increase on the cost sheet, due, usually, to the fact that the cleaning must be done between shifts.

The accompanying sketches show how the sump for the main pumping station can be kept practically free from all foreign matter, such as particles of coal, slate and wood.

On one side of the main sump, a shallow sump is made, not exceeding 2 ft. in depth, and separated from the main reservoir by a concrete wall about 6 in. lower than the top, or high-water level.

The water from the mine is either ditched or pumped into the "settling sump," where the coal or rock is deposited, and the clear water flows over the wall into the main sump. A 1x12-in. board, used as a baffle, will prevent pieces of wood from being carried into the main sump.

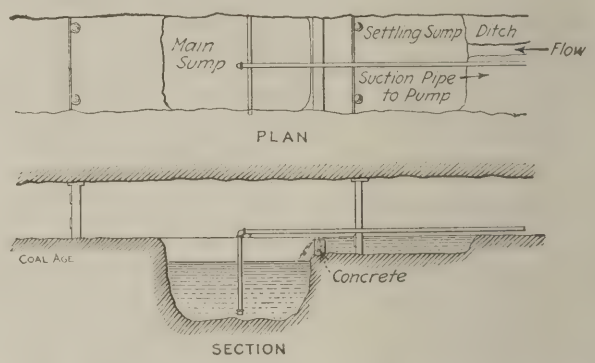

Fig. 1. Plan and Section of Settling and Pump Sumps

The settling sump can be cleaned periodically by the pumpman, during the regular working hours, and the life of the valves in the pump increased materially, as the cutting of these parts is due almost entirely to the amount of foreign matter in the water passing through the machine.

Fig. 2 shows a method of protecting the suction of a pump drawing its supply from a temporary sump.

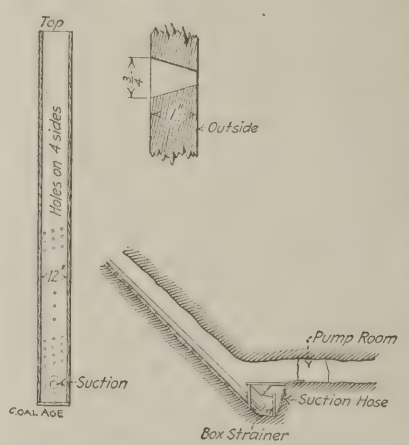

Fig. 2. Method of Protecting the Pump Suction in a Temporary Sump

When the slope was first sunk, a skip pit was made, and the mine cars dumped into skips; the pit was also used as a sump, and the pump suction was covered by coal, wasting from the skips. Later, a box made of 1x12-in. boards, with holes ¼ in. on the outside, and ¾ in. on the inside, was used; the pump suction being connected near the bottom of the box. When the pit filled up, the water level rose, and the water entered the box higher up, the taper in the holes preventing the coal from entirely choking them up.

The heat radiating surface of any electrical conductor varies as its diameter, while the current-carrying capacity varies as the square of the diameter. In consequence, the current density in large conductors will be less than in small for an equal temperature rise. It has been found impracticable on this account to use insulated conductors larger than two million circular mils except in special cases.

*Tennessee Coal, Iron & R.R. Co., Birmingham, Ala.

The Victoria Mine at Lunen, Germany

By F. Schulte

SYNOPSIS—A detailed description of one of the most modern of European mines. The production averages about one ton of coal per man per day, which is far below the individual production of miners in America. The sociological arrangements are unique and quite complete. Electrical hoists were not considered on account of greater first cost.

At present the daily output of the Victoria Mine, at Lunen, Germany, is about 2600 tons, with 2700 workmen on its payroll.

The general arrangement of the respective buildings and workshops, as finally accepted after several changes had been made while the shafts were being sunk, is shown in the plan, Fig. 2, Fig. 1 giving a photographic view of the plant.

Fig. 1. General View of the Surface Plant

The building, which serves both for administration purposes and for the comfort of the men, is found near the entrance to the mine, on the open square at the center of the village. Through this building the mine shafts, Nos. 1 and 2, are entered by crossing the foot bridge over the railway tracks. The main haulage shaft is No. 1, situated close to the screen house and the loading station, while further westward are the washery and the coal tower.

The buildings for the hoisting engines are south of each shaft, on opposite sides of the machinery building; directly beyond the hoisting-engine building of shaft No. 1 are the direct-fired boilers, with the gas-fired boilers further to the west, adjoining the coke ovens and the byproduct factory. To the eastward are the general workshops and the dump is near the river Lippe.

The Administration and Mine Buildings

Entering the main office or administration building, which faces the village, the first room to be met is the checkroom. The rooms for the foremen and manager follow, with windows on the square and doors opening upon the central payroom, which is further surrounded by the offices for the mine boss and the pay clerks. Leaving the payroom, the main corridor leads to the mine shafts, and, on the right of this passage are the pickrooms and the storeroom for giving out the supplies.

On the second floor, reached by the main entrance, the room nearest the stairs is given over to the superintendent, who, from his windows, has a general view over the plant. The offices facing the square are occupied by the pit manager, surveyor, machinery superintendent and draftsmen, and, on the other side of the hall are the bookkeeper and the head clerk. The baths for the officers and foremen are further along the hall to the left, the lamproom being on the right hand as the men go toward the shaft entrance. The lamps are handed back on the other side of the lamproom by the men returning from work and leaving the building on their way homeward.

The Miners' Building contains locker-room for 2403 men, 118 ft. long by 66 ft. wide; on opposite sides are the shower rooms, 14½ ft. wide. To warm the water for the showers, it is fed into an elevated tank, whence it is forced through a heater, and then pumped back into the tank, the circulation being kept up until the desired temperature has been secured. The water flows by gravity to the showers. The heating system for the building is by hot water and forms part of the bathing system, so that there is no steam anywhere, as will be described later.

It was sought, in planning these buildings, to so arrange these rooms and passages that the movement of travel should be subject to no interruption. The men going to their work pass along a special stairway to the lamp delivery room, thence to the covered foot bridge; while the men coming from the mine leave their lamps on the

Note—Translated in abstract by Henry B. Binsse from "Glückauf."

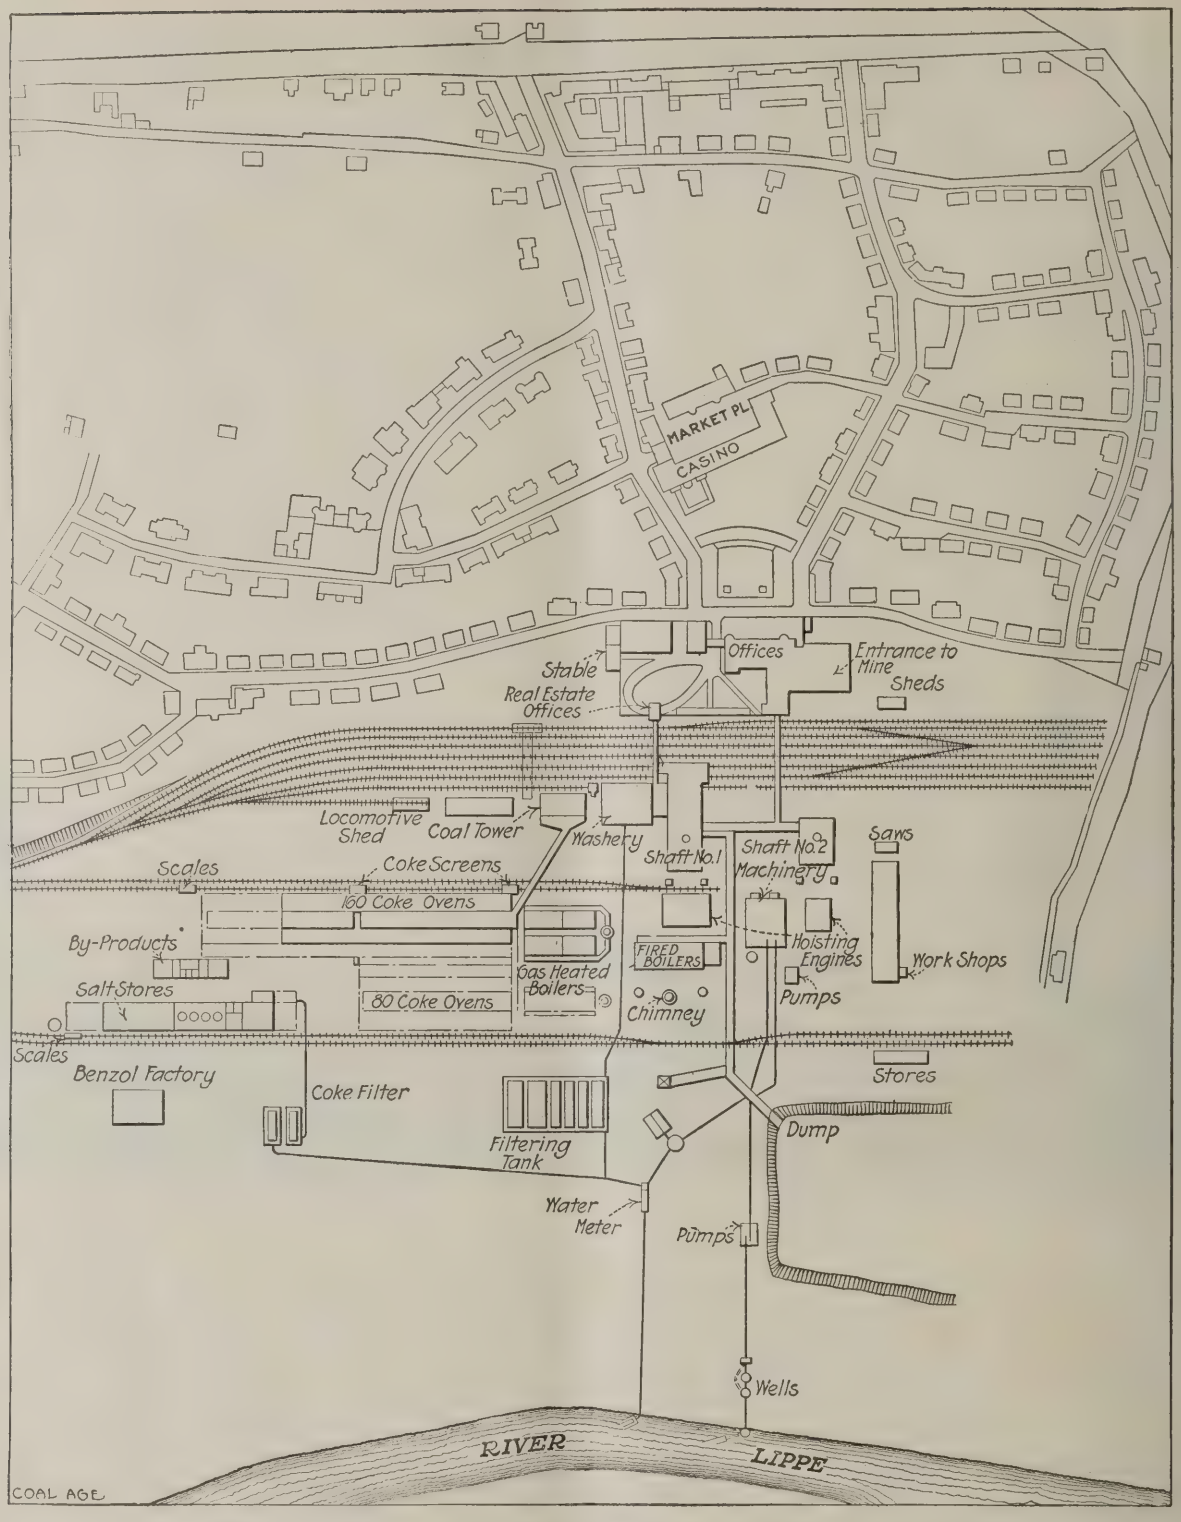

Fig. 2. Layout of Colliery Plant and Workmen's Village

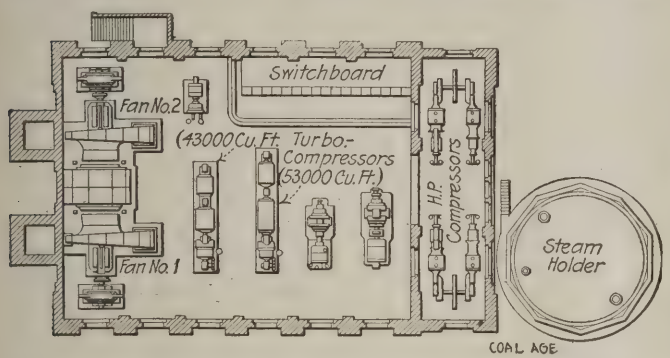
other side and have their own exit. There are also, Fig. 4, rooms for the medical service and first-aid work.

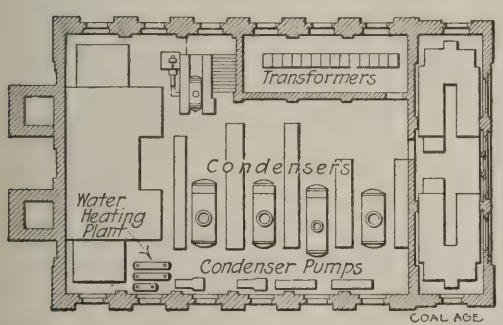
Hoisting Plant

The shafts are 262 ft. apart and have a least diameter of 19½ ft. The air level is 1704 ft., the working level 2000 ft. No. 1, the main shaft, is provided with a double lift while shaft No. 2 is used for lowering timber and material chiefly and has but a single lift. The four floors of the cage in shaft No. 1 carry two cars each, so that eight cars are hauled at a time. The cars weigh 1030 lb. empty and carry 1675 lb. of coal. The hoisting engines are of the twin-cylinder type, the exhaust being used in the steam turbines, as it is well known that it is the best economy to use the exhaust of hoisting engines for heating and for turbines. Electrical hoists were not considered on account of the greater first cost.

The leading dimensions of the three hoisting engines are the same—cylinder, 42 in. diameter by 71-in. stroke, with 30 to 40 r.p.m. The engines are designed for 175-lb. pressure at 482 deg. F. superheat, with a net load of 14,300 lb. and a maximum load of 20,000 lb. from a depth of 2500 ft., at 55 ft. a second, at 103-lb. pressure and 15-lb. back pressure. The screen contains three loading units,



two for screening and loading lump coal, the third for loading the coal as it comes from the mine.



The washery has a normal output of 200 tons hourly and a maximum of 240 tons, and is electrically driven.

Coke and Byproducts Plant

There are two batteries of 80 ovens, and two of 40 ovens, with a plant for the production of tar, benzol and ammonium sulphate. The coke is pressed from the retorts by electrically driven machinery. The coking screen is arranged for 160 ovens.

The boilers are all single flue, alike in size, the working pressure being 175 lb. The battery of fired boilers consists of eleven boilers, with 105 sq.ft. heating surface each, internally fired. The gas-fired battery is made up of 19 boilers of a like capacity. The gases have a temperature of 1900 deg. F. The boilers are all under cover, the arrangement being shown in Fig. 5. The width of the span is 98 ft., the side spans are 13 ft. each.

Figs. 3 and 4. Showing General Arrangement in the Main Machinery Building

Superheaters

To lessen the condensation losses in the steam pipes, a superheating device is attached to each stoked boiler, which yields a temperature of about 500 deg. F.; the superheated steam has its own pipe system. The saturated steam from the gas-heated boilers is led to two superheaters, where it also is heated to 500 deg. F. The feed water is purified as well as preheated.

The main machinery hall is 77 ft. wide by 125 ft. long, and the general layout of its contents is shown in Figs. 3 and 4. It is provided with a 1000-kw. and a 328-kw. turbo-generator, the former for day and the latter for night service. The alternating current is used at 2000 volts and 50 cycles. The turbines make 3000 revolutions and are designed for 25 per cent. overload. The bearings are kept cool by the forced circulation of the refrigerated lubricating oil, and the air used for cooling the generators is filtered.

There are two electrically driven fans, giving a maximum output of 350,000 cu.ft. per minute.

There are two turbo-compressors, one taking 43,000 and the other 53,000 cu.ft. per hour, which are driven by two-stage turbines and may be operated either by live steam or exhaust steam from the hoisting system, the latter being the regular working condition. The air is cooled to 176 deg. F. at 88 lb. pressure on leaving the compressors. All the exhaust steam is collected in a steam holder near the main machinery building.

There are two high-pressure air compressors, one being for reserve. The steam cylinders are 17¾ in. and 29½ in. diameter by 19¾ stroke, and at 120 revolutions, each cylinder compresses 525 cu.ft. atmosphere to 2200 lb. pressure per minute, consuming about 275 hp.

Individual surface condensers are provided beneath each turbine, experience having shown that this gives the best vacuum, a most important feature in turbine economy. The air and water pumps of the two turbo-compressors are driven by a high-pressure steam turbine exhausting into the large turbine. The pumps for the turbo-generators are electrically driven. All the water for condensation is driven from the river Lippe; but, before use, it is allowed to settle in large tanks.

Fig. 5. A Street in the Village

Heating Plant

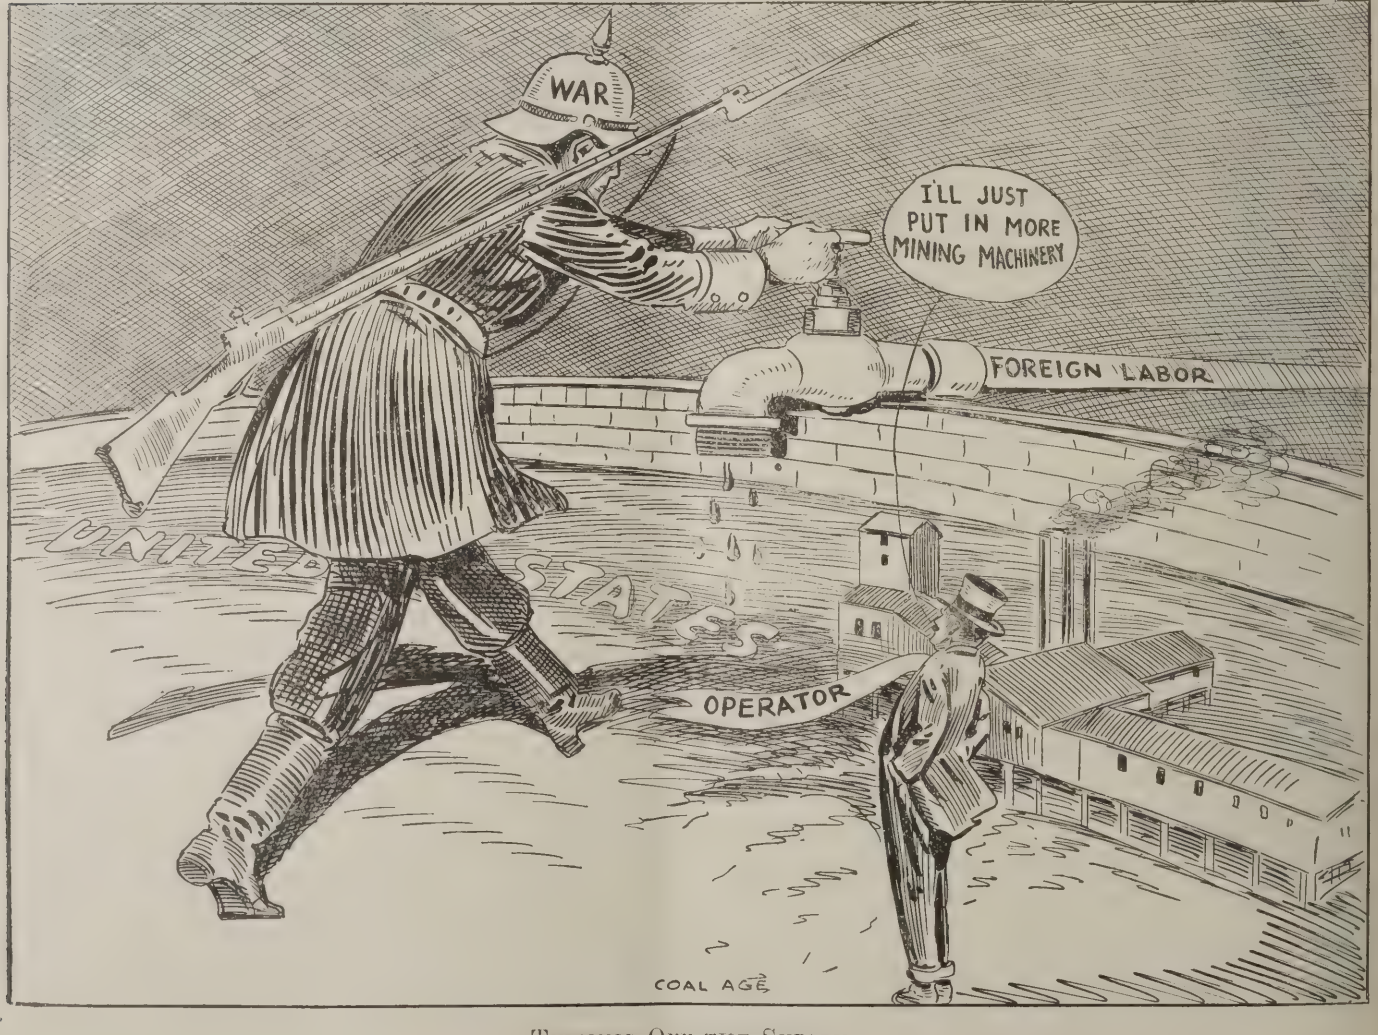
In the desire to keep the steam plants as compact and as concentrated as possible, a hot-water heating system was decided upon, thus doing away with all condensation losses, leaky stuffing-boxes and never ending repairs, as well as the noise from the steam hammer.

This system takes in the baths, workshops and offices. The water is heated by exhaust steam, three heaters in the basement of the machinery building having a heating surface of 475 sq.ft. and are of the brass water-tube type. The circulation pumps are electrically driven, the rotary pumps delivering 275 gal. a minute.

In planning the workmen's village, stress was laid upon making the walk to the mine a short one and upon creating pleasant attractive surroundings (see Fig. 2). There are 70 homes for officers and 637 houses for the men, generally of the several-family type. All are equipped with electric lights and each has its garden and shed. The streets are planted with trees and lighted by electric-

ity. On the main street is a market place, on the south side of which is the casino, with restaurant, music and card rooms. There is a school for very young children, where the little ones are cared for while their mothers are attending to their housework. There is also a school for sewing and cooking. Milk and mineral water find a large sale at the mine entrance.

Natural Gas Breaks Record



The production of natural gas in the United States in 1913 was the greatest in the history of the industry, surpassing that of any previous year in both quantity and value. The total gas production in 1913 is estimated by B. Hill, of the United States Geological Survey, at 581,898,239,000 cu.ft., valued at $87,846,677, an average price of 15.10c. per thousand cubic feet, as compared with a production of 562,203,452,000 cu.ft., valued at $84,563,957, an average price of 15.04c., in 1912, the increase being 19,794,787,000 cu.ft. in quantity and $3,282,720 in value.

Of this total product, about 32 per cent. was utilized for domestic purposes, or 184,885,662,000 cu.ft., valued at $50,522,415, an average price of 27.33c. per thousand cubic feet, and 68 per cent. was utilized for industrial purposes, or 397,012,577,000 cu.ft., valued at $37,324,262, an average price of 9.4c. The industrial consumption includes gas used for both manufacturing and producing power.

West Virginia led in 1913 in quantity of natural gas produced, 245,453,985,000 cu.ft., valued at $34,164,850 being the states output. Pennsylvania was second in quantity produced, with 118,860,260,000 cu.ft., valued at $21,695,845. On the other hand, Pennsylvania was the leading state in 1913 in quantity of natural gas consumed, with 177,463,230,000 cu.ft., valued at $28,709,565, and Ohio second with $128,204,722,000 cu.ft., valued at $27,055,824.

The extraction of gasoline from natural gas, or casing-head gas, from oil wells in the United States has become an industry of some importance in the last three years. Returns received from producers of gasoline of this character indicate that the production in 1913 amounted to 24,060,817 gal., valued at $2,458,443, an average price of 10.22c. per gallon, as compared with a production of 12,081,179 gal., valued at $1,157,476, in 1912, and 7,425,839 gal., valued at $531,704, in 1911.

In 1913, West Virginia produced 7,662,493 gal. of natural-gas gasoline, valued at $807,406; Oklahoma, 6,462,968 gal., valued at $577,944; Pennsylvania, 3,680,696 gal., valued at $405,186; California, 3,460,747 gal., valued at $376,227; Ohio, 2,072,687 gal., valued at $212,404. The balance of the 1913 output was produced by Illinois, Colorado, New York, Kentucky and Kansas.

Turning Off the Supply

The Haldane Flame Test for Blackdamp

Special Correspondence

SYNOPSIS—Effect of blackdamp noticeable in dimness of lights and rapid breathing. Blackdamp is not carbon dioxide, but a variable mixture of noxious gases. Depletion of oxygen proportional to amount of blackdamp present in air. Flame unsteady and easily extinguished as percentage of blackdamp increases. This fact is made the basis of the Haldane flame test for blackdamp. Description of apparatus used and manner of its calibration.

While the percentage of firedamp in mine air can be readily estimated by means of the cap on a lamp flame, no equally simple test has been hitherto available for estimating the amount of blackdamp in mine air. When their lamps burn dim or go out and their breathing becomes deeper and more rapid, these effects are attributed by miners to the presence of blackdamp in the air.

In chemical textbooks blackdamp is still treated as synonymous with carbon dioxide (CO_2), which mistake has led to much confusion. Pure carbon dioxide may be generated in a mine, and this gas is of frequent occurrence in some French coal mines, but no large amount of the gas has hitherto been found in any coal mine in this country.

Blackdamp, as ordinarily met with in mining, is simply nitrogen mixed with about 5 to 20 per cent. of carbon dioxide and some little oxygen may be present. It is the residual gas resulting from the various oxidation processes continually going on in mines and the surrounding strata. The oxygen is mostly consumed, leaving all the nitrogen and perhaps a little unconsumed oxygen; while the amount of carbon dioxide formed depends on the nature of the substance oxidized and other conditions. Thus, if iron pyrites (FeS_2) is oxidized no carbon dioxide is formed in the process, although the sulphuric acid formed may subsequently liberate more or less carbon dioxide from calcium carbonate (limestone). If, on the other hand, wood is oxidized, most of the oxygen consumed is converted directly into carbon dioxide.

It might perhaps be more logical to discard the use of the term "blackdamp" and refer only to the deficiency of oxygen and excess of carbon dioxide in mine air. To the miner, however, blackdamp has a very real meaning. Although the proportion of carbon dioxide in blackdamp varies within the limits mentioned, the character of the mixture is quite definitely described by its effect on both lights and men. There is therefore ample justification for retaining the name in mining practice.

When air is mixed with blackdamp, the oxygen percentage of the air is lowered in proportion to the amount of blackdamp added. The percentage of diminution of the oxygen is thus a measure of the percentage of blackdamp present; but firedamp or some other gas, if present in an appreciable amount, would, of course, help to lower the percentage of oxygen. In naked-light mines, however, firedamp is seldom present in appreciable quantities, so that the deficiency of oxygen is, practically speaking, a measure of the percentage of blackdamp in all such mines.

It is clear, then, that a suitable flame test could be graduated either to indicate the percentage of oxygen, or what seems simpler, to indicate the percentage of blackdamp present in the air of open-light mines. As the oxygen percentage in air diminishes, the flame of a candle or lamp is affected in two ways. In the first place, the light given steadily diminishes, being about 30 per cent. for a decrease of 1 per cent. in the oxygen; and the flame will no longer burn when the oxygen has fallen from normal (20.9 per cent.) to about 17.5 per cent. A further effect is that the flame becomes less and less stable as the percentage of oxygen diminishes, and is more easily blown out by any chance draught or movement. To those who work or move about in such air this effect is plainly evident, as their lights are constantly going out. It is upon these facts that the test I am about to describe is based.

When a thin lighted taper is held inside a glass tube an

The Haldine Flame-Test Apparatus

upward draught is produced by the heated air column in the tube; and this varies in strength as the taper is held higher up or lower down in the tube. The draught tends naturally to blow the taper out and the flame is extinguished at a point lower down or higher up the tube, depending on the percentage of oxygen present. The tube chosen for this purpose is 7 in. long and 0.75 in. inner diameter. The principal graduations are in percentages of blackdamp from zero up to 10.5 per cent.; and there are, besides, corresponding subsidiary graduations in percentages of oxygen, reading from normal (20.9 per cent.) down to 18.8 per cent., at which point the taper ceases to burn in the tube; and when held upright it will no longer burn outside the tube with less than about 18.2 per cent. of oxygen or 13 per cent. of blackdamp. When the taper is held in a horizontal position, however,

it continues to burn until the percentage of oxygen has fallen to about 17.2 per cent., which corresponds to 18 per cent. of blackdamp. There is thus a wide range through which the proportion of blackdamp can be estimated by the taper and tube.

The tube and tapers used in these experiments, which demonstrate the Haldane flame test, are shown in the accompanying figure; and the following tables are interesting. Table 1 shows the results of experiments made in a closed chamber, with the object of finally testing the graduation of the tube. No vitiation of the air was caused by breathing, but only by the combustion of the tapers used in the test. While each test was being made air was breathed from the outside through a tube, until after a sample had been taken for analysis. The air was thoroughly mixed by a fan before each test and the percentage of moisture was kept at about 2 per cent. The taper, held vertically, was extinguished when the oxygen fell to 18.2 per cent.

TABLE 1. RESULTS OF EXPERIMENTS MADE IN CLOSED CHAMBER

Percentage of Oxygen Found by Tube	Percentage of Oxygen Found by Analysis	Percentage of Carbon Dioxide	Percentage of Black Damp Indicated by Tube	Percentage of Black Damp Found by Analysis
20.90	20.90	0.56	0	0.1
20.45	20.33	0.49	2¼	2.9
20.15	20.13	0.65	3¾	3.8
20.00	20.67	0.71	4½	4.1
19.65	19.63	1.07	6¼	6.2
19.25	19.32	1.33	8	7.7

As shown by Table 2, however, the same accuracy cannot be expected in tests made underground, unless troublesome corrections are introduced for the varying percentages of moisture in the mine air and the varying proportion of carbon dioxide in the blackdamp mixture; and unless great care is taken to observe the exact point at which the flame is extinguished.

TABLE 2. TESTS MADE UNDERGROUND

20.9	20.78	0.16	0	0.7
19.7	19.73	1.02	6	5.9
18.9	19.20	1.51	9½	7.9
19.5	19.65	1.06	7	6.1
20.7	20.77	....	1	0.8
20.5	20.73	0.12	2	1.0

It will be seen that in every case but one the indication of the tube was correct to within about 0.2 per cent. of oxygen or 1 per cent. of blackdamp. These experiments indicate, however, that this method is sufficiently delicate to make it very useful in estimating the percentage of oxygen or blackdamp in the mine air. For ordinary practical purposes, it is greatly preferable to a chemical analysis, as it gives the information at once and the test can be reported in as many places as desirable.

The tube method must not, however, be supposed to do more than it actually accomplishes. For instance, it does not detect carbon monoxide in air containing afterdamp or fumes from explosives or an underground fire, which might be excessively dangerous although the tube test would not show it; but, nevertheless, the tube is a more practical means of testing for blackdamp than a lamp.

Commutating Poles for Mine Locomotive Motors

By J. C. Barry*

SYNOPSIS—This is a clear and concise statement of the factors governing motor design and performance; also the reasons for and effect of commutating poles upon the magnetic field of the machine and upon the commutation.

The May 9 issue of Coal Age contained an article entitled, "Interpole Motors for Mining Locomotives," which generally depreciates the desirability of employing this type of motor for mining work. The paper contains certain contradictory statements, in which the point of view seems to have been changed at will to suit the argument at hand.

For instance, at the beginning it intimates that the initiative in the application of commutating poles to mine-locomotive motors was taken by certain manufacturers, principally for the purpose of reducing cost, but later it states that there is no particular difference in the cost of production between the commutating-pole and the non-commutating-pole motor.

It further maintains that the commutating-pole motor should not be recommended for mine locomotives on account of greater complication and because there is no gain in efficiency, although there are no facts advanced to substantiate the latter statement.

Although the statement regarding cost is questionable, it would seem, if true, an argument in favor of the commutating-pole motor; as it is both legitimate and commendable to reduce the production cost of any commodity without depreciation of quality and with ultimate benefit to the purchaser.

Were it not for the fact that the article referred to attempts to show that the commutating-pole motor as applied to mine locomotives has no advantage over the non-commutating-pole machine, the whole subject might be dismissed without further comment. It is the purpose of this paper, however, to show that the introduction of commutating motors for mine haulage is as legitimate and important as their application to railway traction work, where they have entirely superseded the noncommutating-pole type. To prove this statement, it will be necessary to go into the designs of the two types of motors quite thoroughly, considering the losses involved, their effect on performance and to what extent they can be controlled in the design of the motor.

Motor Losses

In any direct-current electrical motor, the losses can be divided under three heads. The C^2R, or *copper loss,* is due to the resistance of the conductors on the armature and field windings. This loss varies with the square of the current, as will be seen from the formula C^2R = watts lost.

The copper loss is composed principally of two parts, one due to the load or line current and the other due to the idle current that circulates in the short-circuited

*Mine locomotive engineering department, General Electric Co.

turns of the armature winding at the instant of commutation, due to the distortion of the field by the armature reaction.

The core loss can be separated into two parts. One is known as the eddy-current loss and is due to the current set up in the armature laminations by their being revolved in a magnetic field. This loss increases with the square of the number of magnetic lines per square inch, or the density of the field, and with the square of the speed.

The other part, known as the hysteresis loss, is due to the reversals of the magnetic lines of force in the armature iron, as it is being revolved in the magnetic field, which varies with the 1.6 power of the density and directly with the speed. These two losses combined are known as the core loss.

Friction Loss

The third loss is the mechanical, or friction, loss, and is due to the bearing friction, the brush friction on the commutator and the windage.

This friction loss amounts to about 1 per cent. at full load of the energy being supplied to the motor; and, as it is practically equal on all types of machines, it can be eliminated from the discussion.

The combined core and copper losses in a well designed motor will amount to about 12 to 14 per cent. of the input at full load, and about 8 to 10 per cent. of the input at one-half load. At full load, this loss is largely composed of the C^2R or copper loss, but at one-half load it is principally the core loss.

From this, it will be seen that the copper loss is the greatest loss at full load, and the one largely responsible for the one-hour rating of the motor. On the other hand, it will be noted that for loads of one-half or less, the core loss is the principal loss and, therefore, largely responsible for the continuous rating of the motor.

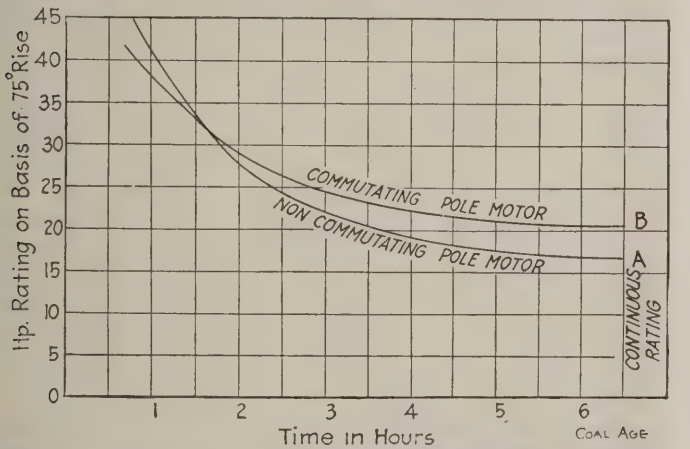


Fig. 1. Horsepower Curves for the Two Types of Motors

The copper loss of the motor is well within the power of the engineer to control. He, therefore, can govern fairly well the hourly rating that the motor is to have. The core loss of a *noncommutating-pole* motor is not so well within the control of the engineer, because he must sacrifice low core loss in order to get good commutation, and in so doing, sacrifice the continuous rating of the machine.

Noncommutating-Pole versus Commutating-Pole Design

In the design of any direct-current motor, the question of commutation must be kept firmly in mind; for no matter how good the other characteristics of the machine may be, if it does not possess the ability to commutate, it must be considered a failure.

In the design of any motor, there are two forces that must not be lost sight of: one of these is the magnetic field produced by the current in the field windings; the other, the magnetic field produced by the current in the armature winding.

These two fields are directly opposed to each other. The former is known as the motor field and the latter as the armature reaction. If the motor field is not sufficiently strong, it will be overpowered and distorted by the armature reaction to such an extent as to cause injurious sparking at the brushes.

This sparking is caused by the armature reaction

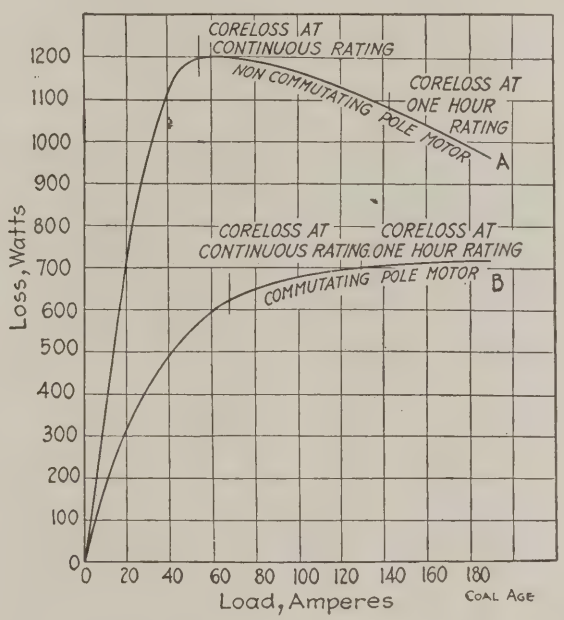

Fig. 2. Core-Loss Curves of the Two Types of Motors

crowding the field flux backward, against rotation, to such an extent as to force the armature coils under the brushes to cut a magnetic field and thereby produce a difference of potential between the commutator bars under the brushes, causing a heavy current to flow in these coils, heating the armature and causing sparking and burning at the brushes.

In order to overcome this difficulty, the designer of a *noncommutating-pole motor* must increase his motor field or magnetic density to a high point, so that the effect of the armature reaction will not greatly distort it. In this way he can effect fairly good commutation and greatly reduce the circulating current and consequently the heating in the short-circuited coils of the armature undergoing commutation. But by doing this, he greatly increases the core loss; for it will be remembered that the core loss increases practically as the square of the magnetic density, or with the square of the strength of the field.

The Design Is a Compromise

It will be seen, therefore, that the design of a *noncommutating-pole motor* of this type is one of compromise. If the designer attempts to run low magnetic density, in order to reduce his core loss, he is sure to get into trouble from commutation, caused by the distortion

of the field by the armature reaction. On the other hand, if he increases the density to prevent this, the core loss will be excessive.

This condition is fully realized; for he knows that the core loss does not greatly affect the hourly rating of the machine, which, unfortunately, is the standard by which all mine-locomotive motors are compared, and also that the core loss will not readily be detected by the operator. He, therefore, disregards core loss and pushes the magnetic density to the limit in his endeavor to secure good commutation, regardless of the heating characteristics of the motor on continuous service.

In the design of the commutating-pole motor, the problem is different. The designer is no longer compelled to rely on high magnetic densities to prevent the distortion of the field by the armature reaction, but makes use of the commutating pole.

This auxiliary pole is magnetized so that it directly

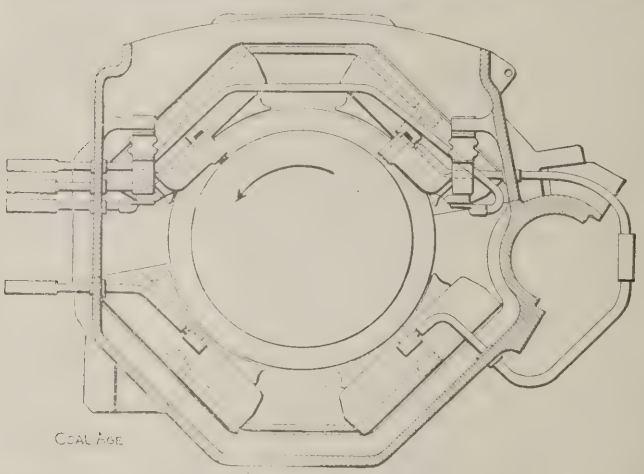

FIG. 3. CONNECTIONS FOR A NONCOMMUTATING-POLE MOTOR

opposes and practically neutralizes the armature reaction in the commutating zone. The motor field is, therefore, mostly relieved of the distorting effect of the armature turns or armature reaction.

By this means the engineer is able to run low densities in his armature core, armature teeth and pole faces, greatly reducing the core loss and consequently the heating, which results in an increased continuous rating of the motor.

The commutating pole, therefore, minimizes the distortion of the field by the armature reaction, fixes the brush position for all loads with either direction of rotation, prevents all sparking and burning at the brushes, and reduces local current in the armature winding to a minimum.

In order to prove these theories and substantiate the above statements, the horsepower time curves and core loss curves of two motors of practically the same one-hour rating are submitted. These curves are the result of actual tests conducted by the writer on these two types of motors. The mechanical features of the two machines are as follows:

	Noncommutating Pole Motor	Commutating Pole Motor
Weight	2130 lb.	1850 lb.
Speed	375 r.p.m.	395 r.p.m.
Mount on	28-in. wheels	28-in. wheels
Mount on	30-in. gage	28-in. gage
Builder's rating ..	40 hp.	37½ hp.

Figs. 1 and 2 show the horsepower time and core-loss curves of the two motors on the standard basis of a 75-deg. C. rise.

Curve *A* represents the noncommutating-pole motor and curve *B* the commutating-pole machine. By referring to curve *A*, it will be seen that the noncommutating-pole motor has an hourly rating of 41 hp., and a continuous rating of 16½ hp., or 40.2 per cent. of its one-hour rating for a continuous rating.

Referring to curve *B*, it will be seen that the commutating-pole motor has a one-hour rating of 38 hp. and a continuous rating of 20.8 hp., or 54.8 per cent. of its one-hour rating for a continuous rating.

If the noncommutating-pole motor had been designed with interpoles, along the lines of the commutating-pole machine herein described, it would have 54.8 per cent. of its one-hour rating, or 22.6 hp. for its continuous rating instead of its present rating of 16½ hp., an increase of 6.1 hp., or 36.4 per cent. in continuous rating.

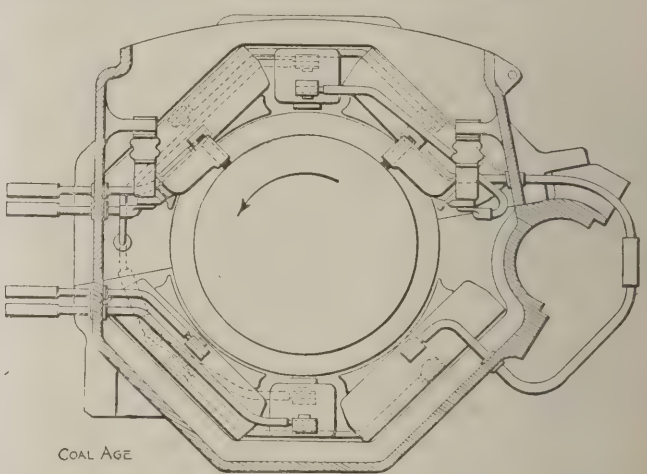

FIG. 4. CONNECTIONS FOR A MOTOR WITH TWO COMMUTATING POLES

It would be pertinent to inquire if this gain of 36.4 per cent. in the continuous capacity of a motor is not of sufficient importance to compensate for the slightly more elaborate field connections of the commutating-pole type.

CONNECTIONS

I would also like to point out that the connections of a commutating-pole motor of the type used in mine locomotives are not so complicated as the writer of the article referred to would have us believe. In the first place, a sketch is shown of a commutating-pole motor with four main and four commutating poles. The leading manufacturers who have adopted this type of construction for mine locomotives as standard, use one-half as many commutating poles as main poles. Therefore, in the conventional four-pole motor, there would be employed two commutating poles instead of four.

The accompanying sketches will give the exact relation between the two types of motors in regard to connections, as actually constructed.

CONCLUSION

It will be seen, therefore, that commutating-pole motors have been introduced into mine haulage for the same legitimate reason that they have been adopted in railway traction work, namely, higher efficiency, improved commutation, reduced core loss and increased continuous capacity.

The Plant of the Lilley Coal & Coke Company

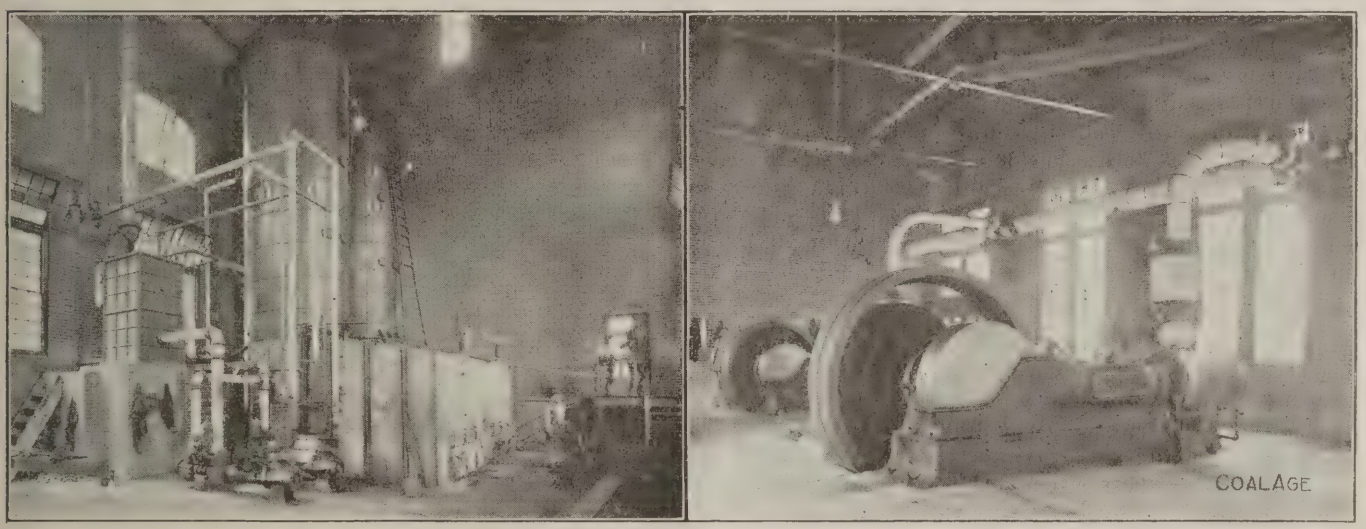
By Lee Llewellyn*

SYNOPSIS—This plant is arranged to load coal upon either railroad cars or river barges. No hand tramming is necessary from the time a trip of loads is uncoupled from the locomotive at the foot of the slope until the cars are again made into trips of empties for return to the workings.

On the Monongahela River, about one mile from West Brownsville, Penn., and provided with a connection to the Pennsylvania R.R., is located the plant of the Lilley Coal & Coke Co.

The officers of this firm are Thomas Lilley, president, John Moffit, secretary and treasurer, and Thomas Elliott, assistant treasurer and superintendent. The engineers are Harrop, Hopkins & Taylor, of Pittsburgh, who were in charge of the construction of the plant.

The company owns 800 acres of coal and 400 acres of surface upon which the plant and town are built. The coal measure operated is the famous Pittsburgh seam, which is here 9 ft. thick, and reached by means of slopes. This particular block of coal is one of the finest on the Monongahela River.



Two slopes have been driven to the coal bed, one being employed for hoisting and the other as a supply and manway. Both are concrete lined and well lighted with incandescent lamps.

The power plant is housed in a building 40x132 ft. in dimensions with a partition separating the boiler room from the engine room. This is of brick construction with concrete floors. Two 300-hp. Wickes vertical boilers equipped with Murphy stokers, two American boiler-feed pumps and a Cochrane feed-water heater of 2000 hp. capacity make up the steam-generating equipment and auxiliaries. Steam is regularly carried at 150 lb. gage pressure.

The engine room contains one 300-kw. and one 150-kw. 250-275-volt compound-wound Westinghouse generators, driven by Harrisburg engines. Provision has been made for the future installation of two more 300-hp. boilers, and an additional 300-kw. generator, also for a boiler coal-handling plant.

The present fan, a 6-ft. Venturi, driven by a 25-hp. General Electric motor, is a temporary installation. An air shaft is now being sunk, at which a permanent ventilating fan will be installed, the make of which has not yet been decided upon.

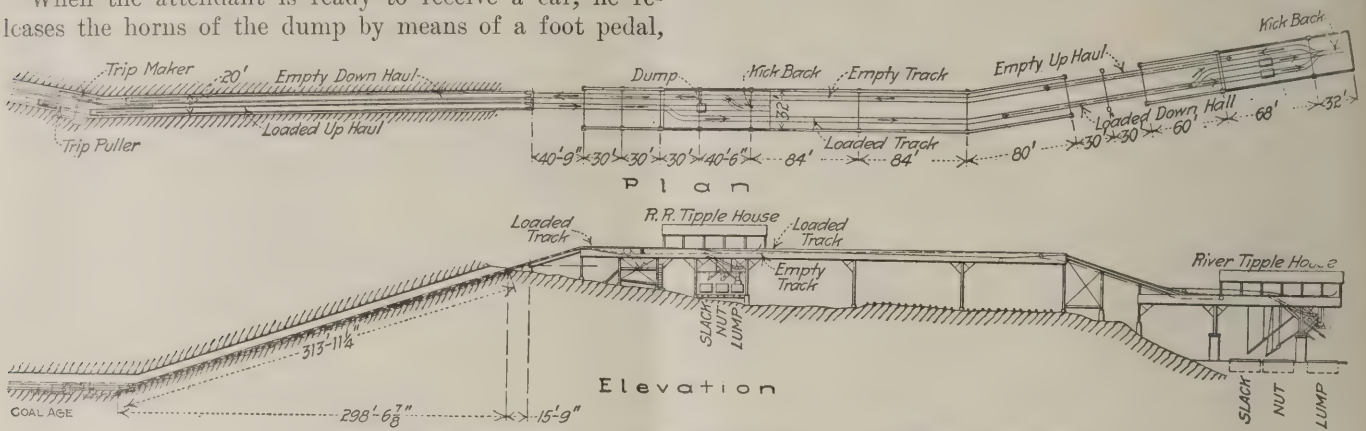
Mine haulage is accomplished by means of Baldwin-Westinghouse locomotives, equipped with cable and crab reels. The cutting machines are of the chain type and were manufactured by the Goodman Electric Co., and the Jeffrey Mfg. Co.

Views in the Boiler House and Engine Room

The power plant, tipple and car hauls were built under contract by the Pittsburgh Coal Washer Co., Fulton Bldg., Pittsburgh, Penn. This firm constructed and equipped the power plant, and designed and equipped the tipple. The Pittsburgh Bridge & Iron Works, however, fabricated and erected the structural steel from plans furnished by the Pittsburgh Coal Washer Co. The Dravo Contracting Co., of Pittsburgh, built the river piers and tipple foundations under contract.

Tipple Operation

The operation of the tipple and head works is as follows:



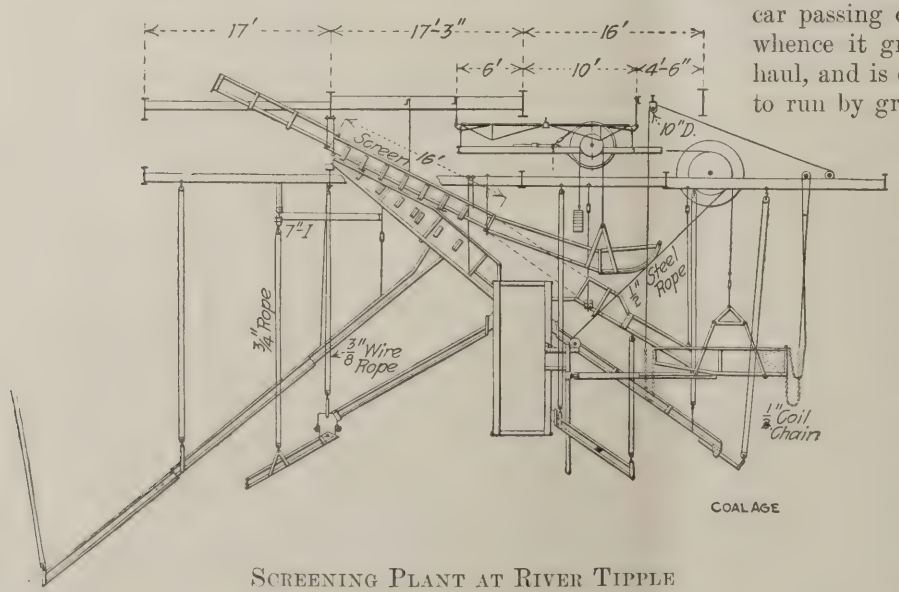
Loaded cars in trips of 80 or less are delivered by the mine locomotive to the trip puller, located at the foot of the slope. This device, picks up the trip, and delivers the cars one at a time to the up-haul chain of the car haul. This car haul consists of two parts, an up-haul chain for loaded cars and a down-haul for empty ones. It operates in a slope approximately 350 ft. long on a grade of 32½ per cent.

The up-haul delivers the loads spaced 24 ft. apart at the rate of 3½ cars per minute at a point 40 ft. beyond

*Pittsburgh Coal Washer Co., Fulton Bldg., Pittsburgh, Penn.

the knuckle from whence they gravitate to a special car-feed regulator and are brought to rest about 20 ft. in rear of the horns of a Phillips cross-over dump.

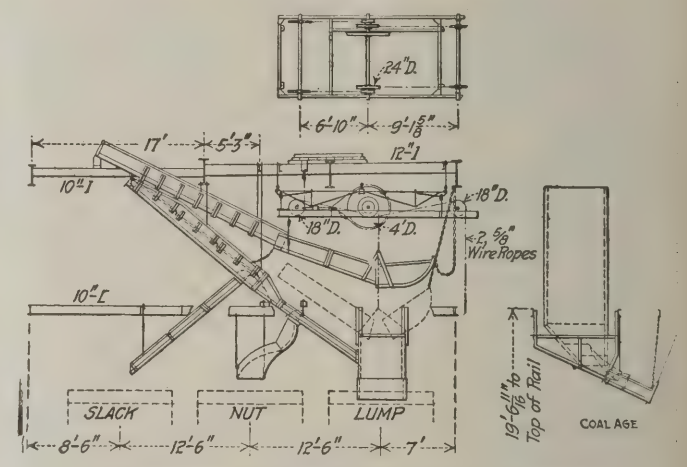
When the attendant is ready to receive a car, he releases the horns of the dump by means of a foot pedal,



Plan and Elevation of the Railroad and River Tipples

and the car gravitates to the dump where the coal is discharged onto a set of gravity screens. The empty car passes over the dump, through a kick-back, from whence it gravitates to the head of the down-haul chain, by which it is lowered back down the slope.

From the foot of the down-haul chain the empty cars gravitate a distance of about 45 ft. to a trip maker, which picks them up and passes them on down the heading on a one-half per cent. favoring grade until a trip of 80 cars or less has been formed.



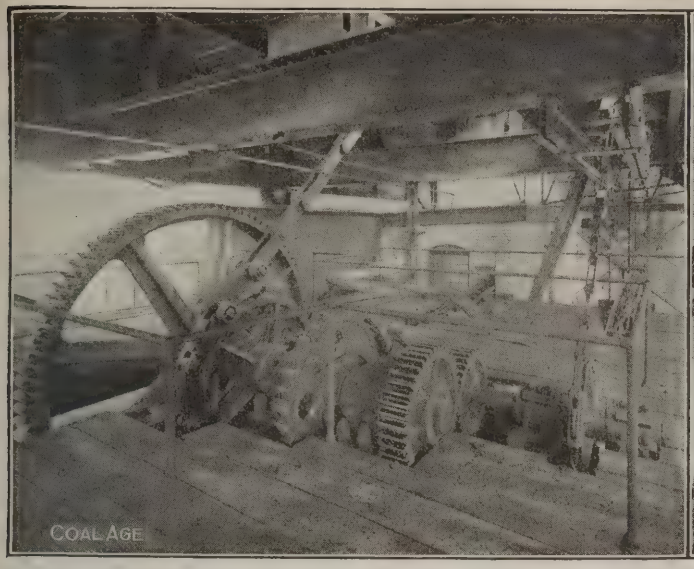
If it is desired to pass any or all of the coal through the river tipple, a switch at the end of the up-haul is thrown, and the cars allowed to pass to a second loaded track, which leads to the river tipple.

In this case the car gravitates from the above mentioned switch to the end of a chain car haul. This car haul consists of a down-haul for loads and an up-haul for empties, and is used for lowering the loads from the level of the railroad tipple to that of the river tipple, and bringing the empties back up again. The head end of the down haul is built on an up-grade of sufficient length to bring the cars to rest after they have gravitated from the main haul, and a special car check is provided to prevent them from running backward.

Screening Plant at River Tipple

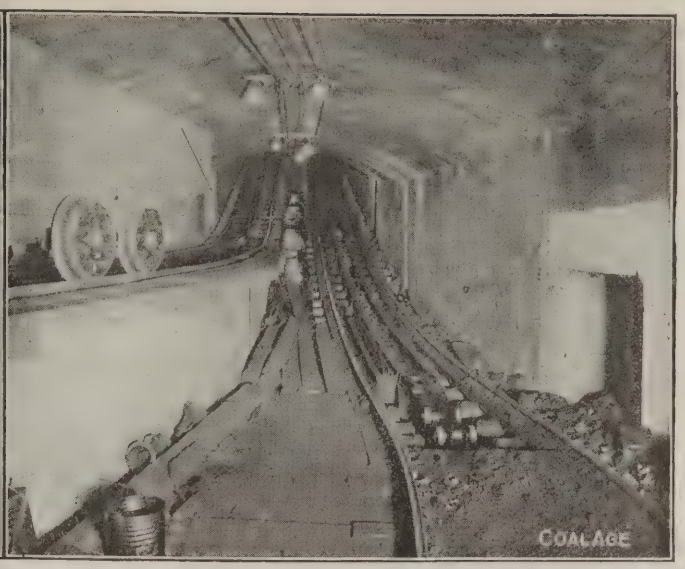
The down-haul chain picks up the loaded car, delivers it to a point approximately 85 ft. in rear of the horns of two Phillips cross-over dumps, from which point it gravi-

Screening Plant at Railroad Tipple



tates to either of the two special car-feed regulators, located about 20 ft. in rear of the dump horns.

Gravity Screens Are Employed



The operation of the car regulator is the same as the one described for the railroad tipple. The coal is discharged into one of two sets of gravity screens, the empty car passing on over the dump to a kick-back, from whence it gravitates to the foot of the empty up-haul, and is elevated to a sufficient height to allow it to run by gravity to the main down-haul chain and return to the mine.

The trip puller above mentioned, located at the foot of the slope, is about 20 ft. long from center to center of the sprockets, and capable of handling a trip of 80 loads on a level grade at the rate of 3½ cars per minute, the total gross weight of each car being about 7500 lb.

The chain is composed of 12-in. pitch links, made up of 2½x⅝-in. bars, connected by 1¼-in. diameter pins, which are turned down at the ends and riveted over steel washers ⅛ in. in thickness. Steel knock-down dogs are inserted in the chain

THE DRIVING MACHINERY FOR MAIN CAR HAUL, LOCATED UNDER TIPPLE FLOOR

VIEW AT FOOT OF SLOPE, SHOWING UP-HAUL AND DOWN-HAUL CHAINS

every 10 ft. to engage attachments on the bottoms of the cars.

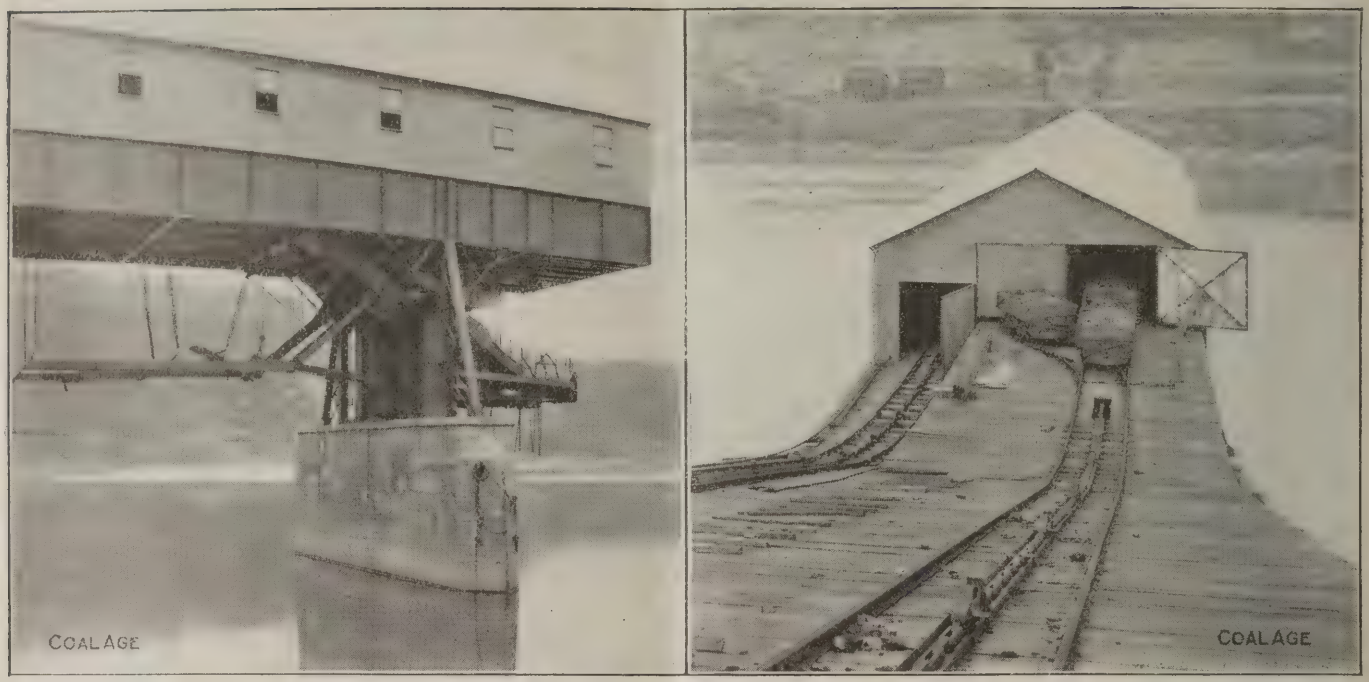
The trip puller is driven by a 25-hp. motor, which also drives the trip maker. The drive is accomplished through a rubber belt and two spur-gear reductions. The head shaft is 5½ in. in diameter and the tail shaft 3 in., the latter being equipped with extra-heavy take-up bearings. The speed of travel is approximately 35 ft. per minute, and a friction clutch is provided for controlling the operation of the device.

The trip maker is about 15 ft. from center to center of the sprockets and is capable of handling empty cars at the rate of 3½ per minute and forming them into trips of 80 or less, on a ½ per cent. favorable grade, the weight of each empty car being approximately 2500 lb.

The 12-in. pitch steel chain is made up of 2½x⅝-in. bars, connected by pins 1¼ in. in diameter, being a duplicate of the trip-puller chain. Steel knock-down dogs are inserted every 5 ft., these engaging an attachment on the bottom of the car. The trip maker is driven from the trip puller's countershaft through a spur-gear reduction and a steel-thimble roller-chain transmission. The head and tail shafts are 4½ in. and 2½ in. in diameter, respectively, and the latter is equipped with an extra-heavy take-up bearing. The lineal speed is about 40 ft. per minute.

THE UP-HAUL IS OF EXTREME LENGTH

The up-haul is approximately 500 ft. from center to center of sprockets, measured along the grade with the inclined portion on an 18-deg. slope for a distance of approximately 400 ft. It was designed to handle loaded mine cars weighing 7500 lb. each, at the rate of 3½ per minute.



The chain is made up of steel links with a pitch of 18 in., composed of 5x1½- and 5x3-in. bars, set two and one and connected by steel pins 2½ in. in diameter. Forged-steel hook links are inserted in the chain every 24 ft. for engaging the attachments on the cars. Each hook link is carried by four cast-iron, steel-bushed traction wheels with chilled faces, these being 6 in. in diameter. The chain between each set of hook links is carried on two of the same wheels. The pins of the chain are extended to form axles for these wheels, both ends being turned

ANOTHER VIEW OF THE CAR HAULS

A VIEW OF ONE OF THE DUMPS

General View of and Approach to the River Tipple

down to 1½ in. in diameter to accommodate hexagon nuts. Steel washers ¼ in. thick are inserted between each nut and wheel, while the nut is held in place by a ⅜-in. cotter pin extending through the axle. Intermediate pins are turned down at the ends and riveted over ¼-in. steel washers.

The up-haul is provided with 8 knuckle rollers 18 in. in diameter to relieve the carriers of the strain at the knuckle points. These rollers are mounted on cold-rolled steel shafts, 2½ in. in diameter, supported in cast-iron flanged babbitted deadeyes, bolted to special structural-steel girders.

The chain is carried forward to a knuckle shaft approximately 55 ft. in rear of the railroad tipple dump and brought down beneath the floor to the head sprocket and shaft, to which the driving machinery is attached. This keeps the machinery entirely below the floor and out of the way.

This haul is driven by a 200-hp. steam engine through a rubber belt and two spur-gear reductions. The speed of the chain is 84 ft. per minute, and the capacity 3½ cars. The calculated horsepower is 133 when the up-haul is loaded and the down-haul empty. When both the up-haul and down-haul are loaded, the calculated horsepower is 105. The estimated maximum stress on the chain is 45,000 lb., but the bearing load on the pins and links is only 6000 lb. per sq.in. of projected area. The links also at the weakest section are stressed to only 6000 lb. per sq.in. in tension. This provides for an ample factor of safety, insuring a long life to the chain.

The head shaft is 9½ in. in diameter of hammered steel, while the tail shaft is 4 in. in diameter and of cold-rolled steel. The knuckle-sprocket shafts are 6 in. in diameter of cold-rolled steel. The first and second countershafts are 4 in. and 3 in. in diameter, respectively, both of cold-rolled steel, while the tail shaft is equipped with extra-heavy take-up bearings, having an adjustment of 24 in.

The head, tail and knuckle sprockets are 58½ in. in pitch diameter of a special car-wheel iron. The pinion on the first set of gears is cut forged steel, 10.4 in. in pitch diameter, carrying 13 teeth, 7½-in. face. The gear with which this pinion meshes is cut cast iron, 72 in. in diameter, 90 teeth, 7-in. face. The pinion of the second

Screen Rig at River Tipple and Operating Rig for the Same

gear reduction is machine-molded cast steel, double shrouded. It is 14.62 in. in pitch diameter, has 13 teeth of 11-in. face. The gear with which it meshes is machine molded, is 95.83 in. pitch diameter, carries 86 teeth of 10½-in. face. These gears are 3½-in. pitch.

The head shaft on the haul is provided with a 6-ft. ratchet wheel to prevent the chain from backing. This wheel is cast steel and has a double forged-steel noiseless pawl.

Rigid Supports Are Provided

The driving machinery is mounted on rigid structural-steel supports. The upper chain guides consist of two 4x3x⅜-in. angle irons, mounted to wood ties. The lower chain guides consist of two, 2x⅜-in. steel bars, secured to wooden stringers. The return strand of the chain runs in a concrete-lined trench.

This up-haul chain is perhaps the largest ever installed. The entire haul is practically noiseless and has worked perfectly from the time it was first started, it being entirely unnecessary to make even a single adjustment. This is a remarkable record, considering the size of the installation.

The down-haul is approximately 460 ft. long from center to center of the sprockets, measured along the slope. The inclined portion is on an 18-deg. angle for a distance of approximately 390 ft. It was designed to handle empty cars weighing 2500 lb. at the rate of four per minute.

The chain is of 12-in. pitch, made up of 3x⅝-in. steel bars, set two and two, and connected by steel pins 1½ in. in diameter. These are turned down at the ends and riveted over steel washers $\frac{3}{16}$ in. thick. Cast-steel knockdown dogs and special disappearing dogs made of cast steel are inserted in this chain every 10 ft.

When the empty car returns to the head end of the haul, it comes to rest on the incline in front of the knuckle, and is held in position by special car checks. A knockdown dog picks up the car and carries it up the incline to the knuckle, where it runs forward about 8 ft. to one of the disappearing dogs, which, in the meantime, has come up to position for its reception. The car is then lowered by this dog to the foot of the slope.

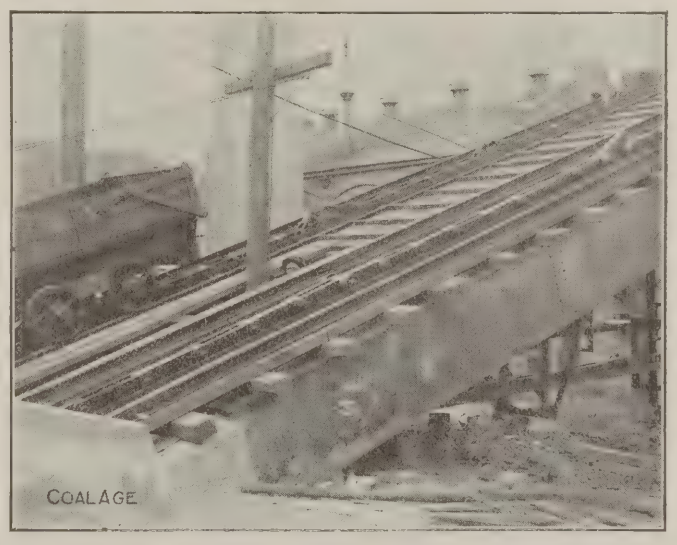
The chain is carried forward to a knuckle sprocket, then brought down underneath the floor to the head sprocket, which is driven from the head shaft of the up-haul through a spur-gear transmission. The speed of the haul is 80 ft. per minute.

Stresses and Pressures Are Small

The calculated maximum stress in this chain is 11,200 lb., and the bearing load on the chain pins is only 6000 lb. per sq.in. of projected area. The chain links at the weakest section are stressed only to 6000 lb. per sq.in. in tension.

The head, knuckle and tail shafts are 6 in., 4½ in. and 3 in. in diameter, respectively, all being made of cold-rolled steel. The tail shaft is equipped with extra-heavy take-up bearings, having an adjustment of 18 in.

The upper chain consists of steel channel irons bolted to wood ties. The lower guides are made up of two 2x⅜-in. steel bars, secured to wood stringers. The return strand of the chain runs in a concrete-lined trench.



The down-haul for loaded cars at the river tipple is approximately 142 ft. from center to center of the sprockets, measured along the haul, with the inclined portion on an 18-deg. slope for a distance of approximately 80 ft. It was designed to lower the loaded cars from the level of the railroad tipple to that of the river tipple at the rate of four per minute.

The chain is of 12-in. pitch, and is made up of bars 2½x⅝ in., set two and two, and connected by 1¼-in. steel pins, which are turned down at the ends and riveted over steel washers ⅛ in. thick. The links and pins are duplicates of those employed in the trip-puller and trip-maker chains. Cast-steel knockdown dogs, and special disappearing dogs, of the same material, are inserted in the chain every 10 ft.

The loaded cars coming from the railroad tipple gravitate to a point in front of the knuckle, being there held in position by special car checks until a knockdown dog delivers each individual car to the disappearing dog, which in turn discharges it at the foot of the slope, from whence it runs by gravity to either one of the cross-over dumps.

Power Must Sometimes Be Absorbed

The motive power for this haul is a 25-hp. motor, which also drives the empty up-haul through a belt and two spur-gear reductions. This drive is connected up to the head shaft of the empty haul. When the two hauls are working under ordinary conditions, it requires 3 hp. to drive them. When all portions of both hauls are loaded, except the slope of the down-haul for the loaded cars, 19 hp. is required momentarily. When only the down-haul slope is loaded, about 8 hp. has to be dissipated. This is accomplished by connecting the driving motor with a suitable control in such a manner as to take power from the line only when it is required for the operation of the hauls and to absorb power, automatically becoming a generator and discharging surplus power to the line when the hauls are so loaded as to drive the motor. A shunt brake is provided to hold the load when the current is off.

The Up-Haul and Down-Haul Chains at the Slope Portal

The speed of this haul is 60 ft. per minute and the capacity four cars. The head and tail shafts are 5 in. and 3 in. in diameter, respectively, both being of cold-rolled steel. The tail shaft is equipped with extra-heavy take-up bearings, having an adjustment of 15 in.

The up-haul for the empty cars at the river tipple is approximately 142 ft. from center to center of the sprock-

cts, measured along the chain with the inclined portion at an angle of 18°, for a distance of 100 ft. This was designed to lift the empty cars from the river-tipple level to that of the railroad tipple at the rate of four per minute.

The 12-in. pitch chain is made up of 2½x⅝-in. bars, set two and two, and connected by steel pins 1¼ in. in diameter. These are turned down at the ends and riveted over steel washers ⅛ in. thick. These links and pins are duplicates of those used in the trip puller and trip maker, also the down-haul for the loaded cars. Cast-steel knockdown dogs are inserted in the chain at intervals of 10 ft., while a special car check is provided to hold the empty car at rest when it returns from the river-tipple kick-back.

This haul is driven from the countershaft of the down-haul for the loaded cars through a belt and one spur-gear reduction. The speed is 60 ft. per minute and the capacity four cars. The head and tail shafts are 5 in. and 3 in. in diameter, respectively, both being cold-rolled steel. The tail shaft is equipped with an extra-heavy take-up bearing having 15 in. of adjustment.

Three Screens Are Provided

In this installation there are three screen rigs, one for the railroad tipple and two on the river tipple. These are of the standard gravity type for this district. The river-tipple equipment is so designed as to make it possible to load nut coal in boats if desired. Each river rig is also designed to operate independently of the other.

The structure in which this apparatus is housed is of heavy steel design. No metal less than ⅜ in. in thickness was used, thus providing for long life. The columns are 14-in. Bethlehem H-sections supporting 8-ft. plate girders, which carry the floor system.

The houses over the screen rigs are roofed and sided with corrugated asbestos-protected metal, manufactured by the Corrugated Asbestos Protected Metal Co., of Beaver Falls, Penn.

It will be readily perceived from the foregoing description and the accompanying illustrations, that great care has been exercised both in the design and installation of this plant. It would appear that all portions of the equipment had been designed with ample size, thus rendering the bearing pressures moderate, which should result in long and efficient operation.

Don'ts for Assistant Foremen and Fire Bosses

1. Don't fail to observe all the rules pertaining to examination for the safety of the workmen in your district.
2. Don't fail to see before entering the mine that the ventilating apparatus is running at the speed designated by the mine foreman.
3. Don't fail to see, before proceeding with your examination, that the air current is traveling in its proper course.
4. Don't forget to examine all places adjacent to live workings when making your examination of every working place in the morning.
5. Don't use a light other than an approved safety lamp when making an examination for gas.
6. Don't fail to mark the date of your examination at or near the face of every place examined by you.
7. Don't fail to examine the entrance or entrances to all worked-out and abandoned places adjacent to the roadway and working places where explosive gas is likely to accumulate.
8. Don't allow any person to pass your station until you have notified him of the condition of his working place. If any danger exists, see that it is removed before any person or persons are allowed to enter.
9. Don't fail to record the results of your examination in the book kept at the colliery for that purpose, stating the location and nature of any danger you may have discovered and immediately report the same to the mine foreman or his assistant.
10. Don't fail to make a second examination, where practicable, of every working place previously examined where men are employed, giving special attention to the roof and sides.
11. Don't fail to place a danger sign across the entrance to every working place and every other place where explosive gas is discovered, or where immediate danger is found to exist from any other cause.
12. Don't fail to place a danger sign at the entrance of every worked-out or abandoned portion of the mine.
13. Don't allow any person (except the mine foreman or some person designated by him) to pass beyond a danger signal until the mine, or that portion thereof, has been examined and reported to be safe.
14. Don't allow any person to remain in any portion of the mine through which a dangerous accumulation of explosive gas is being passed in the ventilating current.
15. Don't allow a light, other than a locked safety lamp, to be used in any working approaching a place where there is likely to be an accumulation of explosive gases.
16. Don't fail to examine the place, and adjoining places, before a blast is fired in a district where locked safety lamps are used.
17. Don't fail to caution the miner that after lighting a charge he should retire to a heading on the intake side of the breast, and not to a blind heading at any time.
18. Don't allow any person to work with a defective safety lamp.
19. Don't fail to report any dangerous condition which you may observe at any time.
20. Don't allow miners to work so far beyond the last set of timbers that their place becomes unsafe.
21. Don't allow an accumulation of gas to be removed by brushing where it is practicable to remove it by brattice.
22. Don't forget that it is the duty of the safety inspector to look only after the safety of the employees, and is not to relieve you of any of your duties.
23. Don't wait for the general inspector to point out dangerous conditions.
24. Don't forget that thorough and efficient examinations and inspections before accidents bring better results than the same work after an accident.
25. Don't forget that we expect you to help us educate the employees to take care of themselves, and this can be done best by personal instruction and attention.
26. Don't allow any person or persons to enter their working places where standing gas has been discovered except for the purpose of removing said gas, and only when accompanied by yourself or a competent assistant, and do not allow any persons to work in the return current until such gas is removed and the place made safe.

Note—From Susquehanna Coal Co.'s book of instructions to employees.

Extracts from a Superintendent's Diary

Our citizens are very fond of having their pictures taken and they never fail to patronize liberally any traveling photographer who happens our way—in this they are not very different from the great mass of ordinary everyday men.

When the artist happens upon his subjects away from home, standing about in groups, discussing mining matters, he has little trouble arranging satisfactory poses, but when he finds them singly at home his troubles begin; for example, if the would-be customer happens to be a groom, the business must be delayed until the bride can be found and then she must be given a chance to bedeck herself becomingly. At last when all seems fixed they recall that brides must always wear flowers and so a hasty search is instituted for a suitable bouquet.

Again they are about ready and the artist suggests the pose. Here again, unforseen delays are encountered. They cannot decide whether the groom should stand and

the bride be seated or the bride stand and the groom be seated. The photographer makes suggestions but his suggestions are not accepted as final. The bridge recalls that somewhere in a magazine she has seen a photograph of a famous man and his bride, and off she goes in seach of the magazine. The photographer hesitates, he would like to pull up his camera and go in search of a more profitable subject, but he has already wasted so much time that he cannot make up his mind to do so. At last all obstacles are overcome and the bulb is pressed.

It would not be fair to assume that women are the cause of all of the artists' troubles. Some times men have to make a good many attempts before they can satisfy themselves about a proper pose. Shall they wear a hat or appear without one; shall they assume an ordinary everyday appearance or must they appear in lodge regalia or possibly as captain of the first-aid squad; and so forth and so forth.

A collection of all of the photographs in a camp very often suggests a complete and interesting history of the camp's existence.

Here is a group picture taken during the last strike with all of the belligerents lined up with their weapons proudly shouldered—Shot guns both single and doubled barreled, mostly breech loading, but not all by any means —pistols, knives, matchetes, and clubs—men, women and children. Subsequently in court they were all very sure that no one was intimidated, but they took pains not to allow any of these photographs to follow them into the court room.

Here is a print showing the first-aid squad just as they looked after their third attempt to penetrate the inside workings, the day after the big explosion. The bunks in the background are part of the temporary morgue. The small flash light, showing all of the frightened women lined up behind a rope was taken about midnight of the same date at the pit mouth.

The blueprint showing the young ladies in holiday attire was made by one of the mining engineers; it is a part of the wedding party welcoming the boss driver and his bride back to camp. The balance of the party were busy re-arranging things in the bride's house according to well-established ideas governing such occasions.

Today we had our prize fruit tree photographed at the request of a nearby Weekly that wants to give our camp a write-up. Think of miners planting fruit trees in rented yards and then living to see the trees bear fruit for their own families.

H. C. Frick Coke Company's Proposed San Francisco Exhibit

A $10,000 model of a coke plant will be one of the features of the United States Steel Corporation's exhibit at the Panama-Pacific Exposition at San Francisco next year, and it is now complete and ready for shipment. The model was made by the H. C. Frick Coke Co. and for several days was on exhibition in the Frick offices at Scottdale. From Saturday until Tuesday the model was inspected by 6022 persons.

The plan is a replica of the Phillips plant of the Frick company. It is 16 ft. wide and 26 ft. long. Every feature of the Phillips plant has been reproduced with a model of the bath house at Standard added.

Briefly, the model shows the shaft and tipple, boiler house, engine house, fan house, lamp house, oil house, blacksmith shop and bath house. At one end is the coke yard, with both block and bank ovens. Careful attention has been paid to detail. When the model is erected at the fair, it will be operated just as a coke plant is. The self-dumping cages will ascend and descend the shaft, the larries will travel from the tipple to the ovens, the wheels of all the machinery will turn constantly.

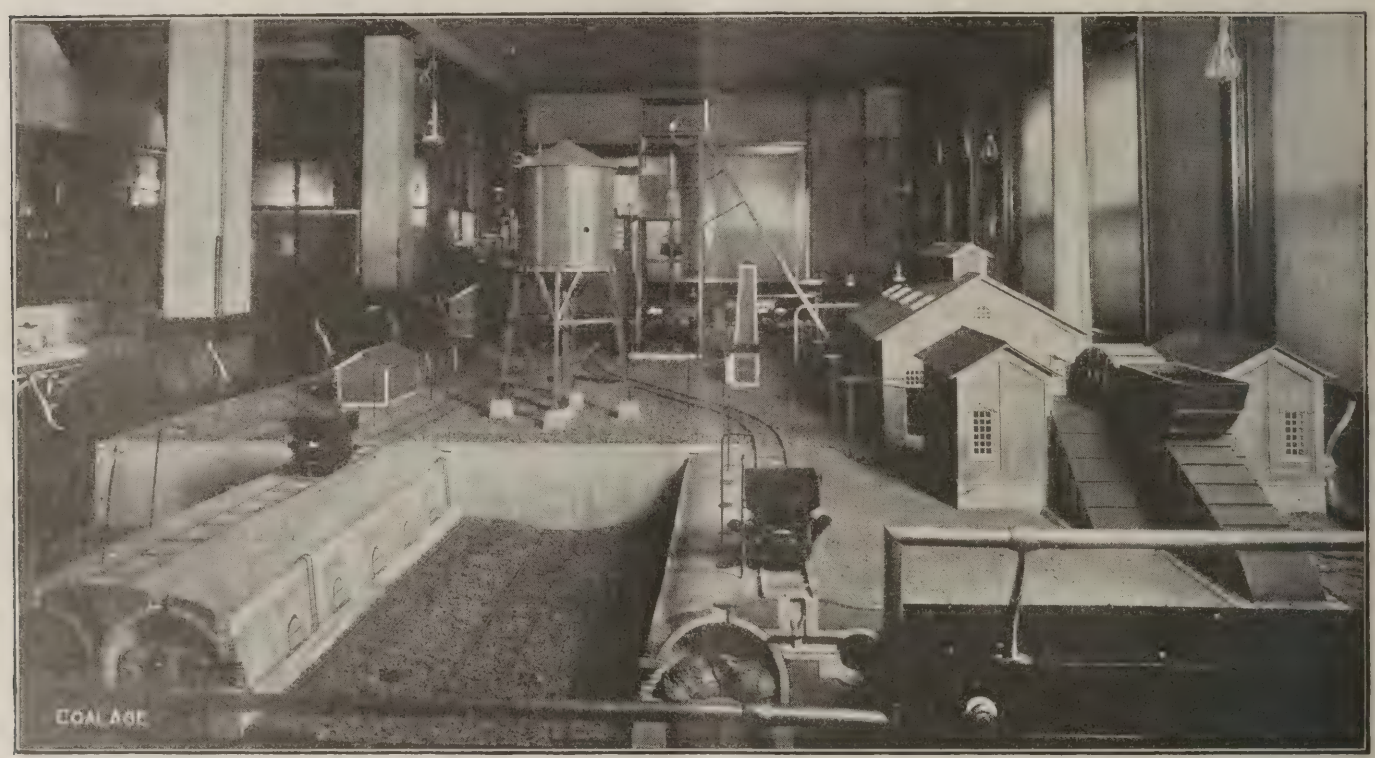
General View of the H. C. Frick Co.'s Panama-Pacific Exhibit

Not only have the exterior buildings been drawn to scale, but the machinery is also in the proper proportion. Most of the work was done at the car shops of the company at Everson. There are exact models of the hoisting engines and those which operate the fans, as well as other machinery about the plant. Ultimately a turbine pump will be installed, and it will be shown how water is pumped out of the mine.

All of the approved safety devices are to be shown, even to the cage about the high ladder scaling the boiler-house smokestack. Regulation danger signs have been placed where they belong. Within the bath house and other buildings, the interior fixtures have been made to scale, down to the individual showers, etc.

On the ground about the tipple the material yard has been laid out, with its steel ties, pit posts and other things that are used about the plant. In the material shed are sections of firebrick, made in the shapes and sizes required for repairing the ovens.

The coke ovens are true to life. After much experimenting it was found possible to secure electric light globes for the interior which exactly imitate the color of a burning oven. At the end of each row of ovens a cross-section has been left open, showing the shape and construction of the ovens. On the bank ovens the waste-heat flues have been added. Through these flues the boilers are fired by the gases from the ovens.



There is the water tank, an important feature of a coke plant, and the hose house for the volunteer fire department. A tower for drying the hose after use was not overlooked. In line with the propaganda of beautifying the colliery surroundings, a flower plot has been laid out along the lawn between the bath house and the lamp house.

The mechanical coke drawer has not been completed, but it will be operated when the model is exhibited at the explosion. An emergency hospital will also be shown. There isn't a detail which has been overlooked, or if it has, none of the superintendents who inspected the model detected it. Virtually every superintendent in the region has passed judgment on the model and pronounced it perfect.

The machinery will be run by electricity at the fair, and the current will be generated from two generators which have been donated by the Westinghouse Electric & Manufacturing Co.

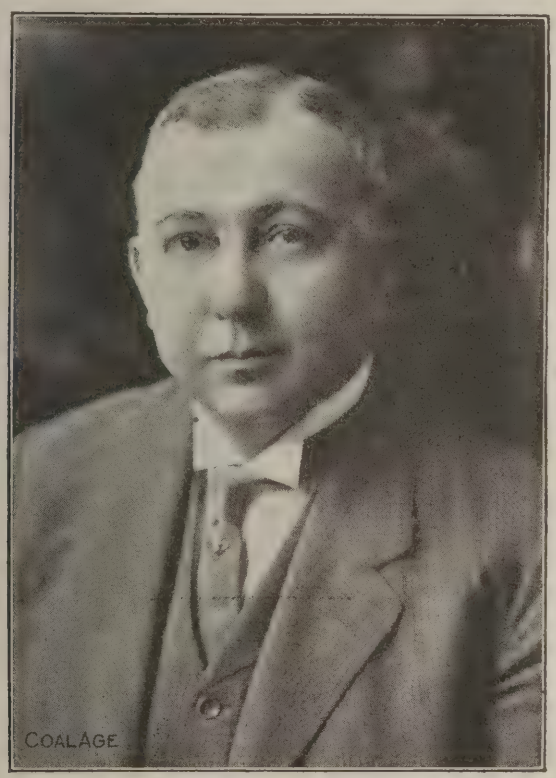
The model was built under the personal direction of T. W. Dawson, assistant chief engineer of the H. C. Frick Coke Co. Mr. Dawson will accompany the model to the Pacific Coast and supervise its erection. The company expects to make the shipment by Oct. 1.

In addition to this model, the Frick company will also contribute a relief map of the coke region, the most complete that has ever been made. There will also be an exhibit of photographs and samples of coal. Various blocks of coal have been contributed from the various fields of the Steel Corporation, but the pride of all will be a column of genuine Connellsville coking coal, 8 ft. high and 16 in. square, bound in steel. There will also be a generous exhibit of Connellsville coke.—*Connellsville Courier.*

ANOTHER VIEW OF THE H. C. FRICK CO.'S EXHIBIT AT THE COMING SAN FRANCISCO EXPOSITION

Explosion at the Mulga Mine

A local explosion occurred at 9 a.m., Sept. 5, at the Mulga mine of the Woodward Iron Co., about 15 miles from Birmingham, Ala. Fifteen men were killed and 16 injured. Two only of the 15 died from the violence of the explosion, the other 13 being suffocated by afterdamp. On Apr. 20, 1910, the Mulga mine was the scene of an explosion resulting in the death of 40 men.



The West Virginia Coal Mining Institute will hold its winter meeting at Huntington, W. Va., on Dec. 9 and 10, 1914. Neil Robinson, president; E. N. Zern, secretary-treasurer.

Who's Who in Coal Mining

Wm. L. Schmick

One of the largest producers of coal in the State of Illinois is the Big Muddy Coal & Iron Co., with headquarters at St. Louis, Mo. The mines of the Big Muddy company in Illinois are located at Murphysboro, Harrison, Herrin and Clifford. These collieries have an output of approximately 8000 tons daily.

Much of the prestige and success of the Big Muddy corporation during the past year is due to the efforts of its vice-president and general manager, W. L. Schmick, whose extensive experience in the selling end of the coal business has been most helpful to his people in these days of semi-darkness in American commercial and industrial

William L. Schmick

life. Mr. Schmick is one of those coal men who realizes in full that to mine coal is not all—there must be a market for the output produced. As a result of this most necessary understanding on his part, he devotes his attention largely to market development, and is as familiar with the trade end as he is with the operating end of the business.

Born in Baltimore, Md., in 1860, Mr. Schmick gained his early education in the parochial school of his native city. When 22 years of age, he entered the coal business as salesman for the Post & Hart Coal Co., in St. Louis. Continuing in his employment until 1886, he then accepted a place as sales agent for the Girard Coal Co., in the St. Louis district, covering this territory for the Girard people until 1891.

When the Consolidated Coal Co. needed an agent to take charge of its northwestern markets, Mr. Schmick was selected to fill the place, and was appointed its representative, with headquarters at Chicago. This job held his attention for six years, at the end of which time the Consolidated company advanced him to the position of general sales agent for their entire output, at the same time changing his headquarters to St. Louis.

That Mr. Schmick served his corporation well for the next eight years is evidenced by the Consolidated company's action in appointing him vice-president and general manager of all its mines in July, 1907. He continued in this position until June 30, 1913. Just about this time the Big Muddy Coal & Iron Co. was looking for a man with sufficient experience to capably fill the place of vice-president and general manager of its coal operations. In its quest for a suitable candidate, Mr. Schmick loomed so large on the horizon of its vision that the search ended with his employment to fill the place he now holds. That was little more than a year ago, but today the comparatively new vice-president and general manager of the Big Muddy Corporation is a most intimate and integral part of the company's organization.

Mr. Schmick's entire attention has been given so exclusively to his coal-mining duties, he has had but little time to divert any effort to outside business interests. He is a director of the Union Fuel Co. in St. Louis, and in October, 1912, was elected president of the Illinois Coal Operators' Association. He is a member of the Mercantile Club, the Sunset Hill Country Club and the Algonquin Club, all of St. Louis. In Chicago, he belongs to the Traffic Club and the Automobile Club. He is an active member of the American Mining Congress and the Illinois Mining Institute.

The Checkweighman

While discussing with the general manager of a coal company the dispute over a checkweighman, which resulted in the shooting up of a mining town, he gave a chapter from his own experience. His miners had selected a checkweighman, who was in the habit of telling all men who came to the tipple seeking work what a poor place that mine was and advising them to look for a job elsewhere. The miners sent a committee to the manager about some misunderstanding, and after it had been adjusted to their entire satisfaction, the manager said he had something he wanted to discuss with them. He detailed to them what the checkweighman was doing and asked them to put some other man in his place.

At a meeting held by the miners shortly afterward, this request was considered, but the hotheads, as usual, argued that as the manager wanted to get rid of the checkweighman, he was just the man they wanted, and so the request was refused. The manager made no comment, but a week or two later, casually stepped up to the checkweighman, who was sitting with a group of men, and called him to one side, sat down and talked with him for ten or fifteen minutes, passed him out a good cigar and when he left him, slapped him on the shoulder in a "hail fellow" spirit. At intervals he repeated this performance. The result was that the same hotheads who had opposed his requests, now said the checkweighman was getting too chummy with the manager and succeeded in ousting him from his position.

The electric current-carrying capacity of an aluminum wire of any given size may be taken as 84 per cent. of the capacity of an equal sized copper conductor.

Editorials

The President and the Colorado Situation

The public has been severe on the Rockefeller family in relation to the Colorado situation, alleging that while owning a large block of stock in the largest company in Colorado, it has been willing to leave the business control in the hands of its representatives. We have been ready to admit that the absenteeism of the Rockefellers was a real misfortune but one which naturally arises from the large extent of their interests.

Now, however, another person has essayed to control the Colorado situation and he, as little as the Rockefellers, understands the conditions which he desires to control. He also is an absentee and dependent on what others tell him. His lack of knowledge is also excusable for he has many other and severe duties pressing on his attention. We refer, of course, to President Wilson.

It is true that he has the results of the congressional investigation to inform him and it is extremely creditable to him that he tacitly overlooks its findings and bases his conclusions on other premises. We congratulate him on knowing that the purpose of committees of Congress is to manufacture political capital.

But we cannot feel he has been fortunate in choosing the men to enlighten him on the situation. One of the two was William Fairley, a member of the National Executive Committee, at least till Nov. 30, 1913, of the organization which was endeavoring by creating disorder to prevent the operation of the mines in Colorado. In 1904, he was an organizer and agitator in that state. The judgment of such a man could not well be regarded as ex parte.

To balance him a man, Hywell Davies, was chosen, who was, at one time for a short while, president of the Kentucky Coal Mine Operators' Association. Apparently he, while passing as a coal operator, has not acted in that capacity for several years, and in fact it is hard to connect him now in an operating way with the coal industry. He appears to be a man well liked by all associated with him, but it does not seem that he was in any way a fit balance for a paid organizer of the United Mine Workers' Union.

These two investigators stayed 10 weeks in Colorado, but at no time, we are told, did they present any letters of instruction or other credentials to the operators. When Mr. Davies first arrived in Colorado, he called on D. W. Brown, J. C. Osgood and S. F. Welborn. About the time he left he called on Van Mater and C. L. Baum. This was the extent of the effort Hywell Davies made to learn the views of the operators, according to our informant, the inquiry of our correspondent having been made at the meeting on Sept. 20, when the signatories of the letter to the President quoted last week were present.

The operators of Colorado, therefore, do not believe that the President has been adequately informed relative to the conditions in that state and the crude proposition offered suggests such a lack of acquaintance. The terms of the proposal are vague and indefinite and overlook facts which everyone should know. Into these defects it is not necessary to enter because the operators themselves in their reply to the president have explained the inadequacy better than we can.

The only right Mr. Wilson had to interfere in Colorado was derived from the fact that a state of disorder existed. The only right by which he may now withdraw, especially now he has taken the arms from the operators, is based on the fact, real or presumed, that disorder will not result. It cannot lawfully be done for any other reason. It must not be done to coerce anyone, to enable anarchic violence to perform what may not, or has not, been done by legislation. If his duty required him to withstrain the lawless, the duty is not now removed unless he believes the lawless are already permanently restrained. He cannot say that he will not permit his truce to be rejected. If he does he sets himself above the law and seeks to legislate for the people.

A New President for the A. I. M. E.

The presidential nominating committee of the American Institute of Mining Engineers is endeavoring to sound the membership for an opinion as to a successor of retiring President Thayer. The deliberations of the committee must be concluded this month, and opinions and ideas on the subject are being solicited.

This seems to be a propitious time for the coal and coke members to enter more actively into the affairs of the Institute. Particularly is this so now that one of the most successful meetings in the history of the Institute is just being concluded under the auspices of the coal and coke committee at Pittsburgh. Under the new regime, a new era has been inaugurated in the Institute; it has been rejuvenated, gained a new vigor and a greater strength, and the fuel members should support this innovation.

With a presidential nomination now up, the question arises, is it not time that the coal men put forward a nominee? There are certainly many convincing reasons for doing so, and the encouragement which the Institute has recently been offering for broadening and enlarging upon the scope of the work of the coal members would seem to indicate that such a proposal would be favorably regarded by the other members.

Strange as it may seem, though the American Institute of Mining Engineers originated in the coal regions of Pennsylvania, there are only three of its presidents who have been in any way directly connected with the fuel industry. And it has now been two decades since a coal man has occupied the presidential chair. We, of the fuel industry, well appreciate the fact that the past presidents have been men of conspicuous ability, some of whose names will go down in history for their noted achievements in scientific lines. But we also feel that the coal industry has produced some equally powerful figures whom the Institute could not honor too highly.

The Export Coal Trade

Let us say first that any coal company or selling agency, with coal of the necessary quality, that is prepared to give extended credit can get foreign business, but it is doubtful if it will always get its money.

There is now plenty of good coal available and there are ships to be had, at a price, but the financial end of the business is far from satisfactory. At present our exporters or those who would be exporters, know but little about ocean freights and charters, port charges, unloading conditions, etc., and will only sell coal f.o.b. tidewater, requiring cash against documents before they will allow their coal to be actually shipped. They know that the financial situation, in the countries needing our coal, is generally bad and will take no risks.

Exporters must realize that the essence of the export coal business is transportation, and that before they can get any large share of the world's foreign coal trade, they must learn the devious ways of ocean transportation and provide the required facilities.

Our competition in the export coal trade, in the past, has been due to opportunities that have come about through outside causes. The British coal strike in 1902 gave us the West Indies markets, which we have never lost, not because we had better coal, but because, in addition to cheaper mining costs, we found iron ore and sugar for return cargoes.

The British strike of 1912 did us little good, because we failed to take advantage of the opportunity offered us to increase our exports, getting only such additional business as was offered, but which we failed to retain when British shipping returned to normal conditions.

Even now, with the chance given by the war, there has been no organized, systematic effort to increase our coal exports; it is all spasmodic, each company for itself after its own plans, usually based on insufficient knowledge of conditions, either of transportation or of finances and credits.

To capture and retain the foreign coal markets, we must follow the example of Great Britain's exporting companies and understand the basis on which they have worked.

They have coal of first-grade quality; we also have coals equally as good in heating value.

They mine and prepare their coal to suit the wishes and needs of the consumer; we prepare our coal as we think best or do not prepare it at all.

They have the necessary loading facilities that will handle coal with the least possible breakage; we load our coal into ships much more quickly, but with little attention to breakage.

They build and own their own colliers; we are entirely dependent on other nations for ocean transportation.

They have established or control their own agencies; we have now but local agents, who often handle British coals and over whom we have no control.

They build or obtain dock and storage facilities and coaling stations; we have nothing of the kind at foreign ports.

They have created and maintain banking and financial agencies in foreign countries; we are entirely dependent on foreign banks.

They meet the consumers' or buyers' views as to sales conditions and credits; we generally refuse to do so and insist on our own conditions, or no sales.

To sum up, the export coal trade is a business in itself and to succeed in it, it must be studied and learned like any other business; every factor in it (and there are many) must be allowed for and made a part of the whole, otherwise we shall never succeed in obtaining and holding our share of it.

The Pittsburgh Coal Co.'s 10% Wage Cut

The Pittsburgh Coal Co. has announced a general horizontal reduction in the salaries of all employees drawing $100 per month or more, excluding, of course, all members of the miners' union. The announcement was not entirely unexpected as it has been under consideration for some time, and it is more or less in line with the policies adopted by several of the largest corporations in the country. In such periods of acute and protracted depression as this country has been laboring under, rigid retrenchment propagandas have been necessary; and, particularly is this so in the case of concerns like the Pittsburgh Co., who are carrying a heavy indebtedness.

While the position of this individual company is not, therefore, open to a general criticism, there is an objectionable phase to the move that cannot be overlooked. This is the throwing of the entire burden of the reduction upon the official personnel of the company and excluding organized labor entirely. The reason is, of course, obvious, the wage agreement with the labor unions making a reduction in that direction impossible without precipitating immediate strikes among the miners. In this we see a tacit acknowledgment of the latent power of organized labor whose rights and demands must be given precedence over every other consideration.

As pointed out in a previous editorial* on this subject, while the company officials form the buffer between capital and labor, the unions have been consistently forcing more and more concessions from capital, which, in the aggregate, has greatly enhanced the cost of living. On the other hand, salaries paid the official forces have, in the main, been stationary, or even suffered a moderate reaction as in the case above cited. The minor official in the coal offices has, therefore, been facing the problem of maintaining appearances commensurate with his presumably superior position, while the buying power of his salary is being constantly restricted to narrower limits. Indeed, one might quite pertinently ask if this constant enhancement in the cost of labor and the apparent small premium placed upon the economic value of the brain worker is not of greater significance as portraying the trend of conditions in our country than is commonly thought.

Even if machines are eventually proved to have a slightly higher fatality rate per man employed than hand labor, their greater productive rate would bring down the death rate of the industry. We are bound to get the coal and we desire to get it with the least number of fatalities possible. We could reduce the death rate per man by putting a few figureheads in safe places below ground, but what good would that do if the death roll per ton mined were unchanged.

*See "Miners' Work and Wages," Coal Age, Vol. 6, p. 273.

The Labor Situation

SYNOPSIS—The labor situation is unchanged everywhere. The operators in Colorado persist in their determination not to yield to the threat of the President, and in eastern Ohio they are holding steadily to a mathematical equivalent of last year's wage.

The Colorado operators are quietly, but nevertheless firmly, of the determination that they will not yield to the President's threat, and so far the President has sense enough not to commit the iniquity he has purposed. So far the troops are not withdrawn, nor will they be, we feel confident, till the strike is settled by the withdrawal of the armed desperadoes from the tented villages throughout Colorado. Perhaps no settlement will be possible till all the perpetrators of past violence are in jail and serving their appropriate sentences. But it is likely that shortages of money will make an earlier termination of hostilities necessary.

Eastern Ohio

In eastern Ohio there is no change in conditions. The miners are extremely angry with Thomas L. Lewis, the former president of the United Mine Workers of America, because he has urged a settlement on the operators' terms. Reproachful letters have appeared signed by Italian miners and by local unions.

Headed by the Maynard and Barton brass bands, about 1000 miners from the unions of Maynard, Neffs, Provident, Fairpoint, Blaine and Barton marched to St. Clairsville on Sept. 28. They paraded the main street and assembled in front of the court-house steps, where several speakers addressed them. The demonstration was caused by the injunction suit filed by the Youghiogheny & Ohio Coal Co. against Obed Hardesty, Father McEachen and others to prevent them from mining coal at the mine recently opened on the Hardesty farm. The company declared that it owned the coal which the miners desired to work.

The striking miners are receiving $3 per week from the union. Sub-district president, C. J. Albasin, left Sept. 28 for Indianapolis. He desires to borrow $10,000 from the Illinois district.

Allowable Impurities

The Ohio Industrial Commission has been asked to determine the percentage of impurities allowable in the Crooksville district. Because the bed is thin and the impurities not so general as in the Hocking Valley field, it was decided that only 75 lb. of impurity should be regarded as permissible, whereas in the field mentioned 100 lb. has been allowed. All impurities over 75 lb. are made subject to docking.

Compensation for Injuries

The smaller operators who lease their mines for operation, will be affected by a decision of the State Industrial Commission, which makes the owner liable for compensation in all cases of injury. This ruling was made in the case of the widow of Thomas McAllister, in a suit against the National Fire Proofing Co., which owns mines at Haydenville, in the Hocking Valley district. It is said that the desire of the mine owners to maintain the mine in good condition has resulted in most contracts to lessees being so drawn that the lessee is not an independent contractor, but merely an agent of the owner. Under the ruling of the commission, the National Fire Proofing Co. is required to pay McAllister's widow $2600. Neither the company nor the lessees were contributors to the workmen's compensation fund of the state.

West Virginia

In the Cabin Creek district, West Virginia, there is much unfavorable comment regarding the union officials, and an "Efficiency League" has been organized. At Beechgrove, near Crown Hill, on Sunday, Sept. 27, a ticket for the district organization was named as follows: Walter Deal, Cedar Grove, for president; W. F. Ray, Black Betsey, vice-president; Norman Atkinson, Crown Hill, for secretary ,and J. L. Workman, national board member.

For purposes of record, we supply the details of two recent settlements in West Virginia. The Four States Coal Co. has made an agreement with the United Mine Workers' Union, District No. 17 The contract will expire Mar. 31, 1916. The new agreement gives unreduced pay to the day workers in the mine, despite the reduction in the hours of labor from 10 to nine hours. The machine-mining rate is unchanged, namely, 31c. per ton. A higher rate had been demanded, but as the company pointed out, the rate paid is higher than that prevailing on Coal Creek and Cabin Creek. The contracts with the Milburn Coal Co. and the Solvay Coal Co. still remain unnegotiated, but a speedy agreement is expected.

The Paint Creek Collieries Co. has at last completed its temporary contract by inserting the rates for machine-mined gas and splint coals. The price for the former is to be 26c. per ton instead of 25c., as in the past. In narrow work, the rate will be 5c. higher. The rate on splint coal will be 29c. instead of 32½c., as was asked and as is paid in the Kanawha district. The general lines of the contract were laid last spring, but the tonnage rate remained as a bone of contention, and an arbitration board was created, consisting of W. Wood and J. Martin for the operators, and A. D. Lavender and W. Patrick for the miners. Finally, to break the deadlock, C. E. Krebs was appointed as referee to sit with the other four arbitrators. The gas-coal price is that paid in the Kanawha district by those operators who are affiliated with the Kanawha Coal Operators' Association.

Recent Judicial Decisions

Effect of Illinois Compensation Act—The Illinois Workmen's Compensation Act does not prevent suit against a coal mining company for injury resulting to a miner from the company's violation of the safety requirements of the Mining Act, such as failure to sprinkle, spray or clean the roadway of an entry, whereby an explosion occurs. (United States Circuit Court of Appeals, Seventh Circuit; Eldorado Coal & Mining Co. vs. Mariotti; 215 Federal Reporter 51.)

Responsibility for Unforseen Accident to Pedestrian—A pedestrian passing along the main track of a railroad company near a coal company's tipple is not entitled to recover from the coal company for injury sustained by her on being struck by a lump of coal bounding from a chute while a car was being loaded at the tipple, in the absence of any showing that the accident could reasonably have been foreseen and prevented by the coal company, although a foreman of that company had assured plaintiff that she might safely proceed along the track. (United States Circuit Court of Appeals, Fourth Circuit; Kirk vs. West Virginia Colliery Co.; 215 Federal Reporter 77.)

Proof of Damage under Breach of Contract—To fill his needs, plaintiff contracted for 50. carloads of coal to be delivered by defendant during a certain period as ordered, and made a similar contract for a like quantity with a third person. Although he ordered out the 50 cars which defendant had agreed to sell, only five were delivered, and the seller under the other contract made no delivery. To obtain the necessary 100 cars, plaintiff was required to buy elsewhere at prices ranging from 50c. to $1.25 a ton above the price at which defendant had agreed to make deliveries. Held, that these facts were sufficient to constitute a basis for computing plaintiff's damages recoverable against defendant for breach of the contract; the two contracts not being so intermingled as to prevent a determination as to the approximate loss sustained by plaintiff through defendant's breach. (Kansas City Court of Appeals, Eaton vs. J. R. Crowe Coal & Mining Co., 165 Southwestern Reporter 1170.)

When a Mine Owner Is Not Required to Support Surface—In the recent case of Graff Furnace Co. vs. Scranton Coal Co., 91 Atlantic Reporter 508, involving the liability of defendant for injury caused by it in mining operations to the overlying surface of land owned by plaintiff, the Pennsylvania Supreme Court said:

"It has long been settled in this state that, where there is a separation of the minerals from the surface, the owner of the mineral estate owes a servitude of sufficient support to the superincumbent estate. That principle was announced in Jones vs. Wagner, 66 Pa. 429, nearly a half century ago, and it has since been uniformly recognized and enforced. Equally true, however, is it that the owner in fee of the entire estate may grant the mineral estate and by apt words in the deed of conveyance may part with or release his right to surface support, and, where he does so, his grantee or those claiming through him may mine all the coal, even though it should result in the surface falling in. The owner of the entire estate, may likewise grant the surface of the land and reserve the mineral estate with the right to mine and remove it without liability for any injury or damage done to the surface, and in such case the grantor or those claiming through him may mine and remove all the coal without being compelled to support the surface. These rights of the owners of the servient and superincumbent estates in land are settled by numerous and some very recent decisions of this court."

The court further holds in this case that a reservation of right of surface support in a deed conveying the surface of mineral lands, need not be signed by the grantee.

Discussion By Readers

The Reverse or Counter-Current Theory

Letter No. 10—The recent discussion by Messrs. Verner, Ashworth and Parfitt shows the deep interest that is taken in everything pertaining to coal-dust explosions. The letter of Mr. Ashworth, COAL AGE, Sept. 5, p. 398, makes it clear that Mr. Verner's claims in regard to the counter-current developed at the moment of a dust explosion in a mine, have not been presented in a manner to be understood by all.

While we may not be able to agree with Mr. Verner wholly, in his attempted explanation of this theory, he should be congratulated for having the courage to voice his convictions in the face of opposition, and for having persistently kept this important subject alive by discussion, for it is by this means that a right conclusion may be reached. Mr. Ashworth, also, can claim an equal share of recognition, because of the tenacity with which he has handled the subject and demanded proof in the shape of observed facts. Many men are satisfied to "play safe," never leaving the old beaten track and the world is none the wiser for their living.

It is not my intention to attempt a discussion of this theory, but to refer briefly to one or two points that have been mentioned. In regard, first, to Mr. Verner's claim of a "counter-current" traveling in an opposite direction to that of the explosive blast, I recall that no less an authority than Sir Frederick Abel tells us that air at a lesser pressure will travel against an explosive wave of greater pressure, which seems to be Mr. Verner's theory, briefly stated.

Again, reference has been made to the Eskmeals experiments undertaken for Mr. Dean, and which showed conclusively that there is an inrush of air during the course of the explosion. This inrush of air is evidently the result of a lowering of the pressure at some point in the mine, which would naturally be followed by a rush of air toward the point of lower pressure. We may justly conclude that the inrush of air, at the Eskmeals experiment, is evidence that a partial vacuum was formed at some point in the tube during the progress of the explosion.

In this connection, it has been pointed out that such a vacuous condition is probably the result of a sudden cooling of the gases, at a point where the conditions were unfavorable for the combustion of the coal dust; as, for example, a wet zone or a stone-dust zone. However, the Eskmeals experiment does not seem to prove that the outrush of the explosive wave and the inrush of air took place at the same time; but, rather, that these currents were produced by certain pressures that acted in their respective directions, the one due to the expansive force of the blast exerted principally along the roof and the other being the atmospheric pressure acting against a more or less vacuous condition at the floor.

If Mr. Parfitt admits that an explosion of any kind, whether it be a shot in the coal or an explosion of coal dust, causes an equal pressure in every direction, it is hard to understand how he would explain his "partial vacuum" at the face of the coal surrounding the shot. I have always considered that when a shot was discharged at the face of a room, the pressure due to the blast was equal everywhere in the room. If this is true, there could be no vacuum formed at *C*, as he states.

When an explosion of coal dust occurs in a mine, it is evident that the mine air is, for the moment, in a state of compression, which extends its influence a slight distance outside beyond the opening. If, now, after the mine pressure has reached a maximum, there is a slight decline, owing to the cooling of the gases in the mine, there would naturally result an inrush of air from the outside, until equilibrium was again established; and this outrush and inrush of air would be repeated one or more times, as the result of other explosions in the mine or any causes that would raise and lower the mine temperature and pressure.

Dawson, N. M.

The Mine Foreman

Letter No. 9—In the discussion of the many qualifications a mine foreman must possess, too much emphasis cannot be laid on the idea that he should be a practical as well as a theoretical man. His success as a mine foreman is not determined by the knowledge he has acquired in the use of textbooks or by his ability to successfully pass an examination for a certificate of competency. The foreman who has a practical knowledge of the work in charge impresses his subordinates that he knows what he is talking about; and his orders unconsciously carry the conviction that his instructions must be carried out and obeyed.

It is important that the mine foreman should be a man of detail. He must make himself familiar with all conditions existing in the mine, by personal investigation. This requires energy and a persistent determination, on the part of the foreman, to observe any infringement of rules or negligence in the performance of work, and to quickly bring the same to the attention of the party at fault. In every mine, men are found who make a continual practice of violating rules, in order to facilitate their work. In many cases, they jeopardize not only their own lives but those of their fellow workmen by a willful act or neglect. It is important that the mine foreman should show himself alive to such practices and maintain the discipline of the mine.

It has been said that the Union will support a man in the violation of rules and orders. My experience in the handling of this class of labor for a number of years convinces me that such a statement is unfair to organized labor. I have known cases where a violation of rules has been presented to the Union as a grievance, by a member, and later brought to me by the pit committee. In every instance, I have been able to show that it was a direct violation of orders or mine regulations and rules laid down for the safety of the men and the security of the

property. As a result, I have never failed to secure the support of the committee.

A successful mine foreman must be capable of judging the amount of work a man should be able to do, in every department of mining and under different conditions, if he works conscientiously. Then, when making his daily rounds, he will be able to detect any shirking of the work. Many men, when not watched closely, are prone to take advantages. They are afraid of doing more work than they are paid for, forgetting that the man who never does more than that for which he is paid, will never be paid for more than he does. This is a true maxim, which every worker should regard.

One of the things that tests the ability of a mine foreman most severely, in many cases, is the attempted installation of new machinery or a new method of operating. In his endeavor, he is almost invariably opposed by the strong prejudices of the workmen, simply because they have never seen the machine or the method tried before. It is a well known fact that men must work with a will to insure the success of a new undertaking. Scores of good and efficient systems and installations have proved a failure through the lack of coöperation on the part of the workmen employed.

For this reason, a successful mine foreman must be competent to change the system of working whenever altered conditions require such a change. In order to introduce chain machines where punchers are being used, it is necessary that the mine foreman select an efficient, reliable man to run the machine and then personally watch the work; calculate the amount of coal undermined; and observe closely the effect of blasting the coal and the amount of powder required, and compare these results with those obtained by the use of the punchers.

When introducing a new system of haulage, or an extra locomotive on the present haul, or when making a new run with the locomotive, the foreman should ride the locomotive himself for a few trips; note the time it takes to make the trip and the time required for switching. The motorman, on that trip, will then know that the foreman has a practical knowledge of the work required and that he must give a plausible excuse for any delay.

Without question, a successful mine foreman must be a good judge of human nature, in order to handle the different classes of men he employs. He must be able to select the best men from those who apply for work and to distribute the men to the best advantage, giving to each man the work he is best fitted to do. This will not only avoid trouble in the future, but will reduce the number of accidents in the mine.

Above all, the mine foreman must be observant of the ventilation, drainage and timbering of the workings. He must provide good ditches at the sides of all roads and see that these are kept clear of refuse. As the successful operation of the mine depends primarily on the *car of coal*, nothing is more important than the maintenance of good roads. It is important that these be well timbered; and the timbering must be closely watched to observe any evidence of excessive weight. A roof cave on a haulage road is not only a menace to safety, but practically shuts down that section of the mine, as no coal can be hauled until the obstruction is removed.

Finally, the mine foreman must be a man of foresight, capable of looking ahead. He must keep his development work in advance, so that any unforeseen occurrences, such as running against a fault, or a squeeze shutting off a portion of the mine, will not reduce the daily capacity of the mine, for which he is responsible.

J. W. Powell, Supt.,
Cottonwood Coal Co.

Lehigh, Mont.

Letter No. 10—I have been a constant reader of Coal Age, for some time, and to say that I have enjoyed the interesting discussions by many of the ablest mining men in this country would be putting it mildly. These discussions have been a great help to me, as they have been to others of my acquaintance. I have been interested in the recent discussion of The Mine Foreman, and offer a few comments, in hopes of seeing it further discussed, as it is a most important subject.

I have often felt that there was a great lack of earnest coöperation between many mine foremen and the respective mine inspectors of the districts where they are located. No argument is needed to prove that the sooner this condition is remedied, the better it will be for all concerned. There should be a feeling of true friendship existing between every mine foreman and his inspector. The same responsibility rests on the shoulders of each of these men, who should work together in earnest efforts to increase the safety of the mine and thus reduce the accident list.

I believe that we have as good inspectors in Alabama as can be found in any state; and there isn't any doubt but that they are doing all in their power to reduce the number of accidents occurring in the mines. It is up to us, as mine foremen, to coöperate with the mine inspector in our own district in every way possible. The way to cooperate with the inspector is to listen to what he has to say when making his inspection of the mine. As a rule, when an inspector recommends a certain thing, it is not his own individual opinion, but the result of matters he has discussed with his associates in mine inspection.

I recall the mine foreman who, just a week or two before the inspector was supposed to make his regular visit to the mine, put on an extra crew of men to clean up the mine and get it in shape for inspection. I have been told of other instances where the inspector told the foreman to make such and such changes; and the foreman would forget all about it or postpone doing the work until nearly the time for the next visit of the inspector, although he was in daily contact with the conditions to be remedied, and there was no reasonable excuse for his delay in making the changes requested.

We should not be so narrow minded as to think that when an inspector offers a suggestion that, in his opinion, would prevent someone from getting injured or killed, it is not a one-man's idea. The suggestion is made in good faith and is born of experience. While the number of mine fatalities is greater in this country than anywhere else, in proportion to the coal mined, we may hope with active coöperation to reduce this high death rate in mining.

Some years ago, the first-aid movement found its way into coal mining. It has proved a blessing to the miners everywhere, and has spread so fast that, now, every coal-producing state has its first-aid teams. The result is that hundreds of lives have been saved through their efforts.

It is essential that every foreman produce a good cost sheet; but it is just as essential that every foreman should devote some time to looking after the safety of the working places and to keep the entire mine in a sanitary condition. He should do this the same, the day *after* the inspector makes his visit as the day *before* the visit. I am glad to say that there has been a vast improvement, in this respect, and the mines today are in a much better condition than they were 15 years ago. Mine legislation has much to do with the advance made in this direction.

In conclusion, let me say, let us all work together in harmony and remember than in unity there is strength; and that great things may be accomplished by coöperation.

J. F. Smith, Mine Foreman,
Alabama Consolidated C. & I. Co.

Lewisburg, Ala.

Electric Mine Locomotive

I notice, in your description of the second electric mine locomotive installed in the anthracite region at the Hillside Colliery (1889), Coal Age, Sept. 5, p. 385, the credit for the design of the machine is given to Mr. VanDerpole. Permit me to correct this statement to the extent of saying that I succeeded in inducing Sup't May, of the Hillside Coal Co., to install this motor, only after guaranteeing a saving in expense of haulage. I designed the machine in Scranton and the order was sent to the Thompson-Houston Electric Co., at Lynn, Mass., before Mr. VanDerpole's connection with that company. The design was rejected on the ground that a 40-hp. machine could not be built within the dimensions specified.

About seven months later, the design was gone over by Mr. VanDerpole and myself, with the result that the only change made was to cut down the weight by making the covers of the wheels in wood. As the machine would not pull its load, I was compelled later to replace these wooden covers with iron castings. I will state, however, that the winding of the motor and the design of the pole is entirely Mr. VanDerpole's work. The conditions in the gangway of the mine would not permit the use of the present trolley pole.

The installation of the plant, however, was entirely in my hands as consulting engineer for the company. The next machine was built entirely under my direction and installed by me, first, at Blossburg and then removed to Forest City, being found too large for the work at Blossburg. The expansion bolts were used, first, at Mayfield, and then on the VanDerpole-Thompson-Houston line, in Scranton. I first adopted the method of running wires through pipes (1888) when lighting the main haulage road at Burley Colliery, Sheffield, England. It may be interesting to note that this was the first coal mine lighted by electricity, which plan I think was first adopted in 1883.

Francis A. Pocock.

Philadelphia, Penn.

Study Course in Coal Mining

The Coal Age Pocket Book

The Operation of a Siphon—There are a few practical points, in the operation of a mine siphon, that demand consideration, as upon these its action depends. The most important of these are the following:

1. In order to **start a siphon,** the pipe must first be completely filled with water, from the intake to the discharge end; and to accomplish this a valve or stop-cock is required at each end of the pipe. When **valves** are used they should be of a type that will offer the least obstruction to the flow of the water, the gate valve being best for that purpose. If **stop-cocks** are used they should provide a passage equal to the full area of the pipe. A **foot-valve** is often used at the intake end, in preference to any other type, because it is automatic in its action.

To **fill the pipe,** all valves are first closed, and water is then poured into the funnel or opening at the summit or crown of the siphon, until both legs of the pipe are full, time being given for the escape of air that may be entrapped in the pipe. When the pipe is apparently full close the opening at the crown and open the valve at the intake end, which will cause a vacuous condition to form at the summit and assist to drain any air still remaining in the pipe, to that point. Again, close the intake valve and displace any air found at the summit by completely filling the pipe with water.

Finally, having closed and sealed the opening at the crown, open first the intake and then the discharge valve. The intake valve should be opened to its full capacity before starting to open the discharge valve. The latter should only be opened gradually, thus giving ample opportunity for overcoming the inertia of the water and reducing the liability of air entering the pipe.

The suggestion of using a **pump** to start a siphon is a poor suggestion. A siphon should be **primed,** in starting, in the same manner as a suction or lift pump is primed to enable it to act.

2. Air-Tight Joints are an absolute necessity to insure the successful operation of a siphon line. Air will enter a pipe, in siphoning, through a joint that is perfectly water-tight. In large pipe lines with flange joints, rubber gaskets dipped in tar should be used. The screw-joints of smaller pipes should be put together with lead. It is a very bad air-leak that can be detected by a lamp or candle held at the joint.

3. The **accumulation of air** in a siphon line cannot be wholly avoided by the effectual submergence of the pipe ends and maintaining air-tight joints. Water always contains more or less air that it has absorbed from the atmosphere and holds mechanically. Under the vacuous condition that exists at the summit of a good siphon, the air held by the water tends to escape and then accumulates in ever-increasing amount till it impedes or completely shuts off the flow of water through the pipe.

This can only be avoided by so proportioning the size of both the intake and discharge pipes that the pipes will flow full and the air be swept away by the water as fast as it accumulates.

The Coal Age Pocket Book

PUMPING

The work of pumping water from a mine shaft or slope is often a difficult problem, owing to the great depth of the shaft or the length of the slope. In many cases, it is necessary to perform the work in stages or lifts, in order to avoid the excessive strains due to a high lift.

The rapid corrosion of the pipes and the valves and linings of the pumps, owing to the action of the acid mine water, is also a matter causing much annoyance and trouble. To overcome this difficulty, it is necessary when the mine water is very corrosive, to use wooden pipes and pump linings or to employ other acid-resisting material.

Theory of Pumping—In the common system of pumping water, there is a suction end and a discharge end. The pump separates these two branches of the system, and is the means or agency producing the flow.

A pumping system is not a gravity system where water flows by gravitation from a higher to a lower level. On the contrary, the pump is the means by which the water is lifted **from a lower to a higher level.**

Briefly stated, the action is as follows:

1. The pump, by its action, produces a more or less perfect vacuum, in the pump barrel behind the piston or plunger, in its forward stroke

2. The pressure of the atmosphere, acting on the surface of the water in the sump or basin, forces it up the suction pipe and through the valves into the vacuous space in the pump barrel.

3. On the return stroke of the pump, the intake valve is closed by the pressure of the water, which is forced out of the pump barrel and through the discharge valve into the column pipe by which it is discharged at the surface.

The Suction Head—This is frequently called the "suction lift" of the pump. It is the vertical height of the center of the pump barrel above the surface of the water in the sump. The suction head must always be less than the atmospheric head, in order to make due allowance for the friction head and the velocity head, which must be overcome before the pump can draw water from the sump. As stated in respect to a siphon, the suction head of a pump in feet, may be taken, in general practice, as nine-tenths of the barometric pressure in inches. With a vertical lift and a good pump, the suction head can safely exceed this amount.

The Discharge Head—This is the vertical height of the free discharge of the column pipe above the pump. The discharge head is only limited by the available steam pressure at the pump multiplied by the square of the ratio of the diameter of the steam cylinder to that of the water piston or plunger.

For example, if the steam pressure available at the pump is, say 50 lb. per sq.in. and the diameter ratio of steam end to the water end is 2, the pump will operate against a water pressure of $50 \times 2^2 = 200$ lb. per sq.in.

Inquiries of General Interest

Steam-Boiler Efficiency

In the October issue of one of my mining journals, in an article entitled "Efficiency of Steam," I read as follows:

As water is converted into steam at 212° F., 14,500° F should convert 68.4 lb. of water into steam (14,500 ÷ 212 = 68.4); but an excellent evaporation under a boiler is 7 lb. of water per pound of coal, or 7 × 100 ÷ 68.4 = 10.2 per cent. of what should occur.

From this statement, the writer of the article proceeds to calculate that, with a feed-water temperature of 100 deg. F. and using steam at 70 lb. gage, the consumption of coal is 30 ÷ 7 = 4.29 lb. per boiler horsepower per hour.

I have compared this article with the answer to an inquiry in COAL AGE, Oct. 3, p. 563, where it is calculated that a consumption of 4.5 lb. of bituminous coal per horsepower per hour, will evaporate 34.5 ÷ 4.5 = say 7½ lb. of water, from and at 212 deg. F. The rate of evaporation per pound of coal consumed is practically the same in each of these cases, making some allowance for difference in the performance of the two boilers used and the range of evaporation from the temperature of the feed water to that of the steam, which is different in the two cases.

I fail to understand, however, the calculation made in the other journal to ascertain the *efficiency* of the evaporation, which is there found to be 10.2 per cent. This seems to me to be a very low efficiency, in boiler practice. Will you kindly state what is meant by boiler efficiency, and what percentage of efficiency should be obtained in ordinary boiler practice, using cylindrical, tubular or flue boilers, such as are in common use at a large majority of the bituminous coal mines in this country.

W. L. A.

Pittsburgh, Penn.

The first portion of the statement to which correspondent refers is wholly unintelligible as it reads and the calculation wrong. As a consequence, the calculated efficiency (10.2 per cent.) is absurdly low. At normal atmospheric pressure (sea level), water is certainly converted into steam at 212 deg. F.; and the calorific power of the coal consumed may be taken at 14,500 B.t.u. In these respects, the above statement is correct.

But, taking the case assumed by the writer of the article in question: namely, the evaporation of water from a feed-water temperature of 100 deg. F., to steam at 70 lb. gage, the heat required per pound of water evaporated, as taken from steam tables, is (Kent) 1183.4 — 67.97 = 1115.43 B.t.u. per lb. On this basis, the evaporation of water per pound of coal is 14,500 ÷ 1115.43 = 13 lb., nearly, instead of 68.4 lb. Then, assuming, as stated, an evaporation of 7 lb. of water per pound of coal burned, the efficiency of the boiler is 7 × 100 ÷ 13 = 53.8 per cent., instead of 10.2 per cent.

It may be remarked, in passing, that it is a very poor boiler and poor coal that will yield an efficiency less than 50 per cent. An average boiler efficiency may be taken as ranging, in practice, from 65 to 70 per cent.; while many uptodate boilers frequently yield an efficiency as high as 80 per cent.

By boiler efficiency is generally meant the ratio of the heat units in the steam generated, to the heat value of the coal consumed. According to the character of the coal consumed, and the type of boiler used, and the adaptation of the fuel burned to that particular type of boiler, the consumption of coal will vary from, say 10 lb. to 2.5 or 3 lb. per hp. per hr. In coal-mining practice, employing cylindrical, flue, or tubular boilers, it is fair to assume a consumption of 4.5 lb. of ordinarily good bituminous coal, per horsepower per hour, and an evaporation of 7.5 lb. of water, from and at 212 deg. F., per pound of coal burned.

Now, taking the latent heat of steam, at atmospheric pressure (sea level), as 970.4 B.t.u., and the heat value of the coal as say 14,000 B.t.u. per lb., gives the theoretical evaporation, from and at 212 deg. F., 14,000 ÷ 970.4 = 14.4 lb. of water, per pound of coal burned. Under these conditions, the boiler efficiency is 7.5 × 100 ÷ 14.4 = 52 per cent.

In the article, to which correspondent has referred, it is further calculated that the generation of steam at a gage pressure of 80 lb. will require 14.2 per cent. additional coal, per horsepower per hour, which is far in excess of the truth. The latest steam tables, now generally adopted, show a difference of only 2 B.t.u. in the steam, at 70 lb. and 80 lb., respectively, at sea level. Since the total heat in the steam above 100 deg. F., at 70 lb. gage (sea level), is 1115.43 B.t.u., a difference of 2 B.t.u. when generating steam at 80 lb. gage, would require less than 0.2 per cent. additional fuel, instead of 14.2 per cent.

It is unfortunate that an article of this character should come so wide of the mark, in dealing with matters of prime importance in coal mining. This is all the more regrettable, because the journal in question assumes that it "is frequently required to correct mistakes in other coal journals, which if not corrected would lead to the impression at home and abroad that *all* were unreliable in their technology."

Sealing Off a Gob Fire

When sealing off an abandoned section of a mine where the slow combustion of the waste coal and slack thrown into the gob has started a fire, where should the first stopping be built; at the intake end or at the return end of the section, assuming gas is generated and considerable firedamp has accumulated within the section?

RALPH BUTLER, Mine Boss,
Keystone Mine.

Shelburn, Ind.

In answer to this question, we cannot do better than to refer to the excellent discussion of the question in COAL AGE, Vol. 1, especially, pp. 617-18. The conclusion was that conditions alone could determine the order of building the stoppings.

Examination Questions

Hoisting Engineers' Examination Held at Terre Haute, Ind., Sept. 10, 1914

Ques.—Name the essential qualifications of a hoisting engineer, as to character, habits, education and experience.

Ans.—He should be honest, straightforward and conscientious in the performance of his duties. He should be temperate and industrious in his habits; painstaking and quick to observe every detail and to respond to any call or signal. He should be able to speak, read and write the English language; and should have a fair education in the rudiments of arithmetic and mechanics. He should be thoroughly familiar with the principles of steam and its generation. He should be fully acquainted with the construction of the steam engine and experienced in its operation.

An engineer should also be able to clean and fire boilers, in case of need; and to make any necessary repairs that may be required in his engine, and set or regulate the valves so as to produce the highest efficiency and best working conditions. This knowledge should be gained by experience in the successful operation of an engine, before an engineer is intrusted with the work of hoisting men.

Ques.—Define clearly the duties of a hoisting engineer.

Ans.—The engineer should be on hand a sufficient time before taking charge of his engine to examine every part and observe carefully its operation. In his spare moments, he should examine carefully and ascertain the condition of all brakes, bolts and other fastenings; replenish the oil cups, and oil and wipe all journals and other bearings. It is the duty of every hoisting engineer to study his engine and acquaint himself with any eccentricities of its operation. He must have a thorough knowledge of the signal code and system and must test the latter, from time to time, to make sure that it is in good working condition. He must never authorize or permit anyone to handle an engine in his charge, during his temporary absence from the engine room; but must hold himself personally responsible for the safe operation of his engine throughout the shift. He must give his entire attention to the care and operation of his engine while on duty.

Ques.—(a) What pipe fittings, valves and other attachments are used in setting up and connecting a boiler and engine? (b) What kind of fittings are necessary to make a boiler as safe as possible, so far as the fittings are concerned?

Ans.—(a) The kind of boiler fittings will depend much on the type of boiler in use; but, in a general way, all boilers are fitted with steam pipes, safety valves, steam gages and water gages or try-cocks for determining the water level in the boiler. Many boilers are fitted with steam domes, but more modern types are equipped with dry-pipes, baffling plates or steam separators for separating the water from the steam as it leaves the boiler or before it enters the cylinder of the engine. Besides these fittings, there are the necessary feed pipes, feed pumps, feed-water heaters, fusible plugs, check valves, blowoff valves, mud drums and manholes for cleaning the boiler.

(b) The usual fittings required for the safe operation of the boiler are the safety valve, fusible plugs, steam and water gages or try-cocks, and the blowoff valves and mud drums.

Ques.—(a) What is a blister on a boiler, and how is it produced? (b) Are cracks and blisters liable to occur in the best plate iron and steel?

Ans.—A blister is a slight wart or swelling produced in a boiler plate by the overheating of the iron, at a point where the latter is unprotected by the water, owing to the formation of scale, or low water in the boiler, or excessive or ununiform firing.

(b) Without due care to prevent the water running low in a boiler, and without proper care in firing; or if scale is permitted to form on the inside of the shell, the boiler plates exposed to the fire are liable to be blistered, regardless of the quality of the iron or steel of the boiler plates.

Ques.—(a) What causes expansion? (b) In what direction is expansion greatest? Give reason for your answer.

Ans.—(a) Expansion is caused by heat; or, in the case of gases, is the result of a reduction of pressure. The heat absorbed by a body drives the molecules of matter farther apart.

(b) Expansion takes place in all directions; but, in a solid body, the expansion is greatest in the direction of its greatest dimension, because in that direction there is the greatest molecular movement.

Ques.—How would you proceed to clean a boiler?

Ans.—To avoid the undue accumulation of sediment in a boiler, it is a common practice among engineers to partially blow off the boiler while it is under steam. When doing this, however, it is important to observe that there is plenty of water in the boiler before opening the blowoff valve. This valve should be opened gradually and when the pressure in the boiler is not too high. The fire should be banked and the pressure allowed to fall to one-third or one-fourth of the normal working pressure; and the valve must be again closed before the water level can fall low enough to expose the tubes of the boiler.

In order to effect a more perfect removal of the sediment, or if it is necessary to remove scale from a boiler, the latter must be completely blown off; but this always results in the hardening of any scale that has formed within the boiler, owing to its being dried quickly by the heat of the boiler after the water has been removed. To avoid this result, it is better to let the boiler go out of service and cool down before drawing off the water. The scale is then more readily removed than when it is dry and hard. In scraping a boiler to remove the scale, care must be taken not to injure the plates, and all joints must be carefully examined to ascertain their condition. All stay-rods, bolts and braces must likewise be carefully examined and tested.

Coal and Coke News

Washington, D. C.

No decisive action has as yet been obtained with reference to the Alaska coal lands leasing bill. It is, however, asserted that the bill will be finally disposed of before the adjournment of Congress. The latter event now appears likely to occur not later than Oct. 17, the leaders having lately made exceptional efforts to arrange a plan that would enable Congress to get away sooner than had been anticipated some time ago, when it seemed as if the session might be so extended as to run into and merge with the new session, which opens, in the natural course of things, at the beginning of December.

Should the Alaska bill be adopted, as is now generally expected, the program as affecting the territory of Alaska will be deemed to be complete, and progress will at once be undertaken in applying the comprehensive system of legislation which will have been placed on the statute books for the benefit of the territory.

The construction of the Alaska railroad, which was provided for some time ago by Congress, will be pushed, and it may be expected that government efforts to develop the coal resources of the territory will become especially active. This is with a view to securing a better and cheaper supply of fuel for the Pacific coast, and incidentally of furnishing the navy with the resources of fuel which it is believed by experts to require in order that it may be strategically in a better position for the future.

Heavy Commodities Should Pay Their Share

The nearer approach of the hearings on the renewed 5 per cent. rate case indicates a probability that the advocates of the side of the roads will endeavor to make good their contention that the heavy commodities which the Interstate Commerce Commission exempted from the operation of the higher rates in the former opinion should be allowed to be included in any advance that may be granted.

Coal representatives will do their utmost to prevent the admission of the heavier products to the class of commodities which may be subjected to the advance, and it is now thought that a reargument, at least to some extent, to show why the advance should not apply to these articles, may be necessary.

It will be contended by opponents, according to current expectations, that not a few of these industries are likely to profit from the war demand and to be able to exact higher prices for export ,and probably in the domestic trade as well. On the strength of this, it will be urged that they ought to be made to bear their share of the work of supplying the increased income needed by the roads. It is still believed that the commission will, however, be likely to adhere to its former position in the matter.

HARRISBURGH, PENN.

The frequency of first-aid contests among the miners, suggests the wide scope of improvement that has been going on in recent years. The encouragement of first-aid work was nothing more than was to be expected from the coal companies. Conditions are far different from what they were some years ago when miners seriously injured were given only the most inexpert attention and suffered the worst of physical agony while they were conveyed many miles to the nearest hospital, and at a time when hospitals were few and far apart.

There is no doubt that the crude methods then in vogue resulted in the death of many miners whose lives could have been saved by prompt and expert attention of the kind now provided at all of the mines. From a small beginning the system has been developed until the first-aid corps actually take the place of the doctor so far as efficient preliminary aid is concerned.

Commendable interest has been shown in other ways. The conveniences established at some of the collieries are a real benefit to the employees. The schools supported by some of the companies for imparting technical instructions in mining and in popular branches are not as universally popular as the companies would like to see them, but in some districts they are an unqualified success.

Some coal companies have spent large sums of money in establishing playgrounds and indoor and outdoor recreation centers, all voluntarily. In the report of the celebration of the Susquehanna and Mineral R.R. coal mining companies, is a statement from Morris Williams, president of the companies, advocating the enactment of a workman's compensation law and casting a shameful reflection upon the Pennsylvania legislature for its past neglect.

There will always be criticism and dissatisfaction among the employees, but over and above the complaint is the fact that the employers have done and are doing much for the welfare of the men who toil underground.

Big Production, Little Trouble

The September production of anthracite coal was the largest of any September in the history of the industry. Official figures of the Bureau of Anthracite Statistics, to be made public shortly will show that the September output was approximately 6,000,000 tons. The previous record for September shipments, made in 1912, was 5,876,496 tons.

In the anthracite field the labor situation is declared to be quieter than it has been for years. There have been one or two instances of local troubles, generally due, it is stated, to some newly elected leader and not sanctioned by the district officials of the United Mine Workers of America. Many of the large producing companies report they have had no trouble for several months.

PENNSYLVANIA

Anthracite

Pottsville—It has been announced by the Philadelphia & Reading Coal & Iron Co. that there will be no further shut downs of the mines on weekdays, except on church and legal holidays. It is stated that the demand for all domestic sizes of coal is heavy.

Scranton—Mitchell Day, Oct. 29, will be observed here with a big parade, to be participated in by mine workers of the city and vicinity. This was the unanimous vote of representatives of 25 locals in a convention recently held here.

Sugar Notch—No. 9 colliery, Lehigh & Wilkes-Barre Coal Co., which has been closed for the past four months, following a cavein which allowed the water of a pond to flood the workings, resumed operations on Oct. 1. More than 700 men and boys are employed at the colliery

Plymouth—The Department of Education of Pennsylvania has notified the School Board that the state will share in the expense of successfully operating vocational schools in the borough, to the extent of paying two-thirds of all expenses A school in mining suitable to prepare applicants for miners' certificates, mine foremen's and assistant mine foremen's certificates, etc., will be opened about Oct. 14.

Nanticoke—The Truesdale colliery, owned and operated by the Delaware, Lackawanna & Western R.R. Co., during the month of September mined, prepared and shipped to market 107,065 tons, which for this colliery is an increase of 200 tons over any previous month. The mines worked 24 nine-hour days, which makes the average tons handled 4668 every nine working hours. The officials and 1900 men and boys employed at the Truesdale have just reason to feel proud of the new record.

Wilkes-Barre—Striking miners at the Dorrance colliery of the Lehigh Valley Coal Co., who refused to work on Sept. 16, on the grounds that they were being unjustly dealt with in regard to the amount of topping required on each car, returned to work on Oct. 1, and the matter will be presented to the company officials by the grievance committee within a few days. The officials since the inception of the strike steadfastly refused to consider the complaint of the men until they would return to work and present the grievance in the regular manner which is now being done.

Hudson—Fire of unknown origin recently completely destroyed the engine house at the Delaware colliery of the Delaware & Hudson Co. The fire was not discovered until it had gained great headway, but was soon overcome by the work of the volunteer firemen. The amount of damage has not been made known.

Bituminous

Pittsburgh—Announcement was recently made that salaried employees of the Pittsburgh Coal Co. not included in the wage agreement with the United Mine Workers of America or other labor unions would suffer a reduction of 10 per cent. in wages. The order was so worded as to apply to employees receiving $100 per month or more.

A long continued period of dry weather has interfered with coal operations in the neighborhood of Pittsburgh. Many of the mountain streams have dried up and mines and quarries have been severely handicapped. Some coal mines have been obliged to shut down, as the price of coal is so low as not to justify the hauling of water.

Jerome—New coal operations are to be located approximately a quarter of a mile below the plant of the Jenners-Quemahoning Coal Co. For the past six weeks, work has been progressing on the construction of a side track and the driving of the slope. The C Prime bed of coal will be worked. John Gibson, Jr., is the manager and owner of the new operation.

Connellsville—Much interest has been manifested lately in an order granted by Judge J. Q. Van Swearingen whereby the Colonial Trust Co. was granted a judgment against the Isabella-Connellsville Coke Co. for $7,043,796. When the court convened, the attorneys reresenting the plaintiff company presented a petition to the court, asking that judgment in the amount named be given against the defendant on account of failure to make an appearance.

The total production of coke for September showed one of the greatest curtailments since the beginning of the year. The month's record showed a total of 1,009,741 tons, as compared with 1,310,333 tons for August, or a loss of 300,000 tons for the month.

Lilly—The first pay of the miners at this place since the first week in April was that of Sept. 26, when the men received about $14,000. Labor troubles have now been adjusted and the condition of the market promises steady employment and good times in Lilly for some months ahead.

Church Hill—The tipple of the Dutch Hill mine burned on Oct. 2. The mine had been sold recently to the Monterey Coal Co. The loss will be about $3000.

The Hillville mine in the Allegheny Valley, which was involved in the late failure of Frank Williams & Co., of Buffalo, has been leased by the receivers, G. B. Bassett, Jr., of Pittsburg, taking the position of sales agent. The mine has a capacity of 500 tons daily.

WEST VIRGINIA

Grafton—A bed of the well known Red Stone coal is being opened at Pyrconnel. The coal is found to be of a quality superior even to the Pittsburgh coal.

Beckley—At the instance of Deputy Mine Inspector L. B. Holiday, W. S. Fink, a mine forman at Sprague, was recently fined $50 for violating Sect. 10 of the State Mining Law, which provides that breakthroughs shall be driven at intervals of 80 ft. along the mine entry.

Charleston—The coal market is now so restricted that many operators along the Kanawha River are experiencing difficulty in disposing of their product. In some instances, slack is being sold as low as 10c. a ton. At another place, the slack is being dumped on the ground at a cost of 10c. per ton, and the lump and larger sizes only sold.

According to Governor Hatfield, the workman's compensation act of West Virginia is working satisfactorily. It is costing the state but 5 per cent. of the premiums collected for administration, has a surplus of about one-half of the amounts paid in, and has taken care of 16,500 claims during its first year in operation. Under the operation of the law 174 widows, 288 children, 38 dependent parents and 63 disabled workmen are being cared for by the state.

Wheeling—The Parrs Run coal mine, located about a mile from Moundsville, was recently sold to a company of Ohio coal men, headed by H. E. Loomis, of Cleveland. The property includes about 1200 acres of coal land and a modern mine which is in operation. This mine is a comparatively new one and employs about 100 men. It is understood that the new owners contemplate making extensive improvements.

Thomas—Superintendent A. Beveridge, of the Davis Coal & Coke Co., at Coalton, W. Va., was recently wounded in an attempted hold-up for the purpose of securing $4100 in miners' pay envelopes. Mr. Beveridge was making his customary trip from the Thomas office with money to pay off the employees at mine No. 41. He had proceeded about half his journey when he was fired on from ambush, his horse receiving several shot in the neck, and he himself being struck in the arm. The horse bolted, carrying him in safety to mine No. 41.

Huntington—A friendly suit of rather unusual nature will soon be filed by the United States district attorney, growing out of the recent Glen Alum tragedy, when the payroll was robbed and several men were killed. The money was in a mail pouch, but was recovered from the robbers after it had been taken. The Government could not identify it, and will therefore sue to recover from the sheriff, who has the money, an amount equal to that found on the dead bandits. This method of settling the difficulty was the suggestion of the sheriff himself.

ALABAMA

Montgomery—No decision has yet been made by the Alabama Railroad Commission regarding the proposed increased freight rates on coal from the Birmingham district. The case has been on trial for the past two weeks, with practically every railroad and the principal coal operators as witnesses, and it is expected that a verdict will be given by the 10th of the month.

KENTUCKY

Louisville—The Eastern Kentucky mine operators are rather pleased over the showing made in the recent prohibition elections in which, in 9 out of 15 counties, the "dry" element voted saloons out altogether. The operators are pro-prohibition because of the higher standards possible in the mining communities when no liquor is permitted to be sold. Probably the direct effect is felt more in Bell County, where the remaining saloons in the Middlesboro section were voted out, so far as the mines are concerned.

Cannel City—The Kentucky Block Cannel Coal Co. has reopened its mine No. 6 after it had been shut down for two years. The mine is a mile and a half from the central-power plant and the coal, containing about 50 per cent. of volatile material, is shot from the solid without being undercut.

Whitesburg—R. T. Peters has begun a coal operation at Viper, on the Louisville & Nashville, near the Letcher-Perry line, and announces that he will begin shipping coal in the next few days. He is an experienced operator and expects to develop a mine that will give employment to several hundred men.

OHIO

Coshocton—The directors of the Ohio Cannel Coal Co. are arranging to develop a large tract of coal land in Bedford Township, Coshocton County. S. C. Priest will be in charge of the development.

INDIANA

Petersburg—D. J. Mackey has sold the Hartwell mines to the Mackey Coal Co., of Evansville, Ind., for $75,000. This includes four miles of railroad, two mines, 2240 acres of coal land, and the town of Hartwell, with 70 miner's houses.

A month's shutdown of the S. W. Little coal mines, at Little, near here, is announced while repairs and improvements are being made in the mines. For the last several months these mines have not been running more than two days a week. They employ 400 men during normal seasons.

Terre Haute—Members of the 150 locals of the Indiana Mine Workers have received nomination blanks, preparatory to the biennial election of officers. Each local may nominate one candidate for each of the offices, the election, under the Australian system, to be held the second week in December. Nominations must be in Oct. 25 and nominees have a few days in which to signify whether they desire to accept the nomination and become candidates.

Brazil—Two new mines are to be sunk south of Knightsville, the Crawford Coal Co. putting down one of them, and the names of the men behind the other mine not yet being made public. It is reported the Miami Coal Co. will sink a mine at Ehrmandale and that a coal-stripping pit will be established near the site of the old Kokomo mine. There is a large body of block coal that can be put on cars by a steam shovel, with the handling of only 10 to 12 ft. of dirt, it is said.

ILLINOIS

Edwardsville—At the receivers sale here on Oct 3, Thomas T. Brewster, general manager of the Mt. Olive & Staunton Mining Co. of St. Louis, purchased the property of the De Camp Coal Co. at the village of De Camp, 16 miles north of here. His bid was $5000. The property according to experts could not be duplicated for less than $100,000. There is a bond issue of $90,000 against the property and unsecured claims of about $15,000. The mines have been in the hands of the receiver since Dec. 6, 1913. The sale must be approved by the Madison County Court.

Duquoin—The Majestic mine, near here, was badly wrecked by an explosion on Oct. 1. The explosion occurred shortly after the shot firers had finished their work and left the mine, and only one person was underground at the time, a member of the night shift, as far as is known. It is reported that it will take some days to find out the extent of the damage to the inner workings of the mine, and at this time it is unknown whether the explosion was caused by powder or gas.

Hallidayboro—The mine of the Muddy Valley Mining & Manufacturing Co. here, belonging to the W. P. Halliday estate at Cairo, and consisting of 5700 acres of coal lands, with surface, with all the mine buildings and properties and several farms, was sold to a syndicate composed of several West Virginia men and one investor from Pennsylvania, by S. J. Burkitt, of Mowequa, Ill. Thirty-six residences are included in the sale, which compose most of the buildings of the town of Hallidayboro. These holdings have been a part of the Halliday estate for a period of about 30 years.

Belleville—In the Circuit Court here a jury returned a verdict of $10,000 against Donk Bros. Coal & Coke Co. in favor of Pete Ragaina, who was injured in a premature explosion while employed as a shot firer.

East St. Louis—The rumor, reporting that the Prairie mine of the Aid Coal Co. of St. Louis would likely be abandoned on account of squeezes, is denied by officers of the company, who state that the mine is in shape to operate at once and can produce 2000 tons per day. They state that the mine has not had any squeezes in a period of about two years.

Peoria—The Wolschlag mine, between Hollis and Bartonville, was recently reopened. The upper works of this operation were destroyed by fire last summer, but have been entirely rebuilt. They are now said to be fireproof in every way, being constructed of steel and concrete . Electric power is used in place of steam.

Canton—It is generally believed that the old Black Hawk mine No. 1 will soon be reopened. This operation was opened first about 20 years ago, and worked well until about four or five years ago. For the last six months the company has had the engines at work pumping out the water, and for two weeks, gangs of men have been cleaning up the débris.

NORTH DAKOTA

Mandan—Farmers in this vicinity are making search for an 8-ft. bed of coal which is said to have been discovered by members of a government mineral survey party. One of the government crew said that the coal bed is the best in western North Dakota, but he was under orders not to reveal its whereabouts.

UTAH

Storrs—One of the five boilers in the steam power plant of the Spring Cañon Coal Co. at this place exploded on Sept. 28, killing two men and seriously injuring three others; also putting the power plant and mine out of commission for some days. It is said that the failure of this boiler was due to a faulty patch on the boiler shell. The boiler itself was hurled about 200 yds., the building in which it was housed was totally demolished, and one of the other five boilers was badly injured, while the rest were put out of commission.

PERSONALS

C. L. Earnest has resigned his position as cashier of the Northfork National Bank to accept the general managership of the Fiat Rock Coal Co., of Bluefield, W. Va.

Jas. A. Richards was recently appointed District Inspector of Mines for the Calgary District of Alberta. His address accordingly changed from Royal View, Alberta, to Calgary.

A. H. Wood, of Petros, Tenn., president of the Petros Coal Mining Co., and consulting engineer for the Turley Coal Co., at Turley, Tenn., is organizing a company to open a mine in the Harlan field of Kentucky, and expects to start development at an early date.

John Stannis, of Mt. Braddock, Penn., was recently presented by the miners of that place with a gold watch appropriately engraved. Mr. Stannis resigned to accept the position of assistant mine foreman at the Phillips works of the H. C. Frick Coke Co. Mrs. Stannis was also presented with a silver tea set.

J. M. Page, of Lafollette, Tenn., superintendent of Rex Mine No. 1, of the Lafollette Coal, Iron & Ry. Co., has resigned. G. Walters, superintendent of Gem mine, at Peabody, has succeeded Mr. Page, and Joseph E. Hendren, mine foreman at the Gem mine, has been promoted to the position of superintendent of that plant.

C. E. Sharpless, general manager of the Nanty Glo Coal Co., the Dixon Coal Co., the Atlantic Coal Co., and the Irona Coal Co., all operated by allied interests in Pennsylavnia and West Virginia, and formerly for several years in the employ of the Berwind-White Coal Mining Co., at Windber, Penn., recently changed his residence and address from Cresson, Penn., to Ebensburg. This change in location did not involve any alteration in either duties or positions filled.

CONSTRUCTION NEWS

Chattanooga, Tenn.—Kerby & Jones were recently awarded the contract by the Chattanooga Gas & Coal Products Co. for grading the site of the coke-oven plant to be erected in Alton Park. The contract includes all grading for foundations, buildings, ovens, and for two miles of railway. The contractors immediately made bond to have the entire work completed by Nov. 1.

Portsmouth, Ohio—Work has been started on the Chesapeake & Ohio spur line from Portsmouth to Columbus, which will parallel the N. & W. between the same points. The construction of a bridge across the Ohio at Portsmouth, at a cost of $3,000,000, is a part of the work to be handled. The building of the new line is the result of the court decision regarding the handling of Chesapeake & Ohio traffic over the N. & W. line, which had been for years regarded as practically a branch of the Chesapeake & Ohio.

Toledo, Ohio—It is stated on what appears to be reliable authority that the receivers of the Cincinnati, Hamilton & Dayton Ry. Co. expect to proceed at an early date with the enlargement of the company's docks and the purchase of new coal-hoisting machinery for use in Toledo. Enlargement of the Cincinnati, Hamilton & Dayton docks above the Fassett street bridge is considered a necessity because of the remarkable increase in the amount of lake coal handled there. The tonnage of coal handled at the dock this year will be the largest in the history of the road. It already exceeds last season's record by 600,000 tons.

Pittsburgh, Penn.—With the opening of three new mining plants by the Pittsburgh Coal Co., three model mining towns will be brought into existence, and approximately 3000 men will be given employment. This work is now being pushed with all possible speed, all of the new plants being on the Montour R.R. The first of the new plants will be three miles south of McDonald; the second, adjacent to Venice, and the third near Hill Station. It is expected that the houses in each town will be ready for occupancy within a short time. A 75-room hotel for miners will be built in each of the towns also. Playgrounds and ballgrounds will be constructed and equipped in the most modern way while the distinct novelty of the new houses will be out-door bath houses. It is believed that this will enable the miners to leave the grime, which is ordinarily carried into the house, behind in the outsde bath house where the change of clothes is made.

NEW INCORPORATIONS

Gadsden, Ala.—The Brown Coal Co., with a capital stock of $2000, has been incorporated. The company will develop a tract of coal land in Blount County, not far from Oneonta. Watt T. Brown, of Ragland, Ala., is president.

Columbus, Ohio—The Whyel Coal Co., of Columbus, has been organized with a capitalization of $10,000, and will engage in coal mining. The incorporators are George Whyel, C. M. Crooks, F. S. Crooks, R. J. O'Dell and W. T. Gano.

Clarksburg, W. Va.—The J. E. Long Coal Co. has been incorporated with a capitalization of $10,000, and will engage in mining. J. E. Long, of Phmiladelphia, is the head of the company, D. D. Britt and others, of Clarksburg, being interested.

Birmingham, Ala.—The Wadsworth-Cahaba Coal Co. has been incorporated with a capital stock of $5000. W. C. Beck is president; L. E. Patton, vice-president and treasurer, and Paul Lanier, secretary. The office is 1107-8 American Trust & Savings Bank Building. The new company has taken over a mine of the Wadsworth Red Ash Coal Co., at Helena.

STATEMENT OF THE OWNERSHIP, MANAGEMENT CIRCULATION, ETC., OCT. 1, 1914,

of Coal Age, published weekly at New York, N. Y., required by the Act. of August 24, 1912.

Editor, Floyd W. Parsons, 10th Ave. at 36th St., New York, N. Y.

Managing Editor, Floyd W. Parsons, 10th Ave. at 36th St., New York, N. Y.

Business Manager, William Le Baron, 10th Ave. at 36th St., New York, N. Y.

Publisher, Hill Publishing Company, 10th Ave. at 36th St., New York, N. Y.

Owner, Hill Publishing Company, 10th Ave. at 36th St., New York N. Y.

Owners of 1% or more of Stock Issued.

John A. Hill, 10th Ave. at 36th St., New York, N. Y.
Fred R. Low, 10th Ave. at 36th St., New York, N. Y.
John McGhie, 10th Ave. at 36th St., New York, N. Y.
Fred S. Weatherby, 1600 Beacon St., Boston, Mass.
Frederick A. Halsey, 356 W. 120th St., New York, N. Y.
G. Eugene Sly, 50 Union Sq., New York, N. Y.
Frederick W. Gross, 215 E. 11th St., Erie, Pa.
Alfred E. Kornfeld, 10th Ave. at 36th St., New York, N. Y.
Emma B. Hill, 80 Munn Ave., E. Orange, N. J.

The balance of the stock issued (less than 1% each) is owned by 70 employees, 3 ex-employees, and 14 others who are wives, daughters or relatives of employees.

Known bondholders, mortgagees, and other security holders holding 1 per cent. or more of total amount of bonds, mortgages or other securities. Mortgage on building held by Dime Savings Bank, Brooklyn, N. Y.

C. W. Dibble, Vice-President,
HILL PUBLISHING COMPANY.

Sworn to and subscribed before me this 30th day of September, 1914.

RICHARD L. MURPHY,
Notary Public.
(My commission expires March 30, 1915.)

INDUSTRIAL NEWS

Columbus, Ohio—Authority has been granted to the Little Miami Railway Co. to issue $306,500 additional stock to compensate the Pennsylvania system for improvements on the line.

Central City, Penn.—The completion of the electric-power installation for the operation of the Berwind-White McGregor mine near here is being pushed. The Berwind-White company is also having more new houses erected for the use of its miners at the new plant.

St John's, Newfoundland—The wreck of the Dominion Coal Co.'s collier "Cacouna" and the safety of her crew were recently reported here. The "Cacouna" from St. Johns for Sydney, Nova Scotia, went ashore at Ferryland between this port and Cape Race. The vessel was built at Newcastle in 1884, and had a gross tonnage of 1451 tons, and is believed to be a total loss.

Buffalo, N. Y.—A Buffalo furnace interest recently closed a contract for 10,000 tons of Connellsville furnace coke for shipment during the month of October at $1.65 per ton. Coke is reported as offered at this price for delivery during this month, although dealers are not willing to accept less than $1.75 for shipment during the balance of the year and some are asking $1.85.

New Orleans, La.—During the past few months, self propelled steel barges have been running between the Alabama coalfields and New Orleans, thus beginning the utilization of a great system of inland waterways. In the past 20 years, the government has spent $8,000,000 in making the waters of the Tombigbee, Warrior and Black Rivers navigable for vessels of 6 ft. draft to connect the Alabama coalfields with tidewater.

Philadelphia, Penn.—It is said that exports of bituminous coal to Mediterranean countries has continued to increase since war in Europe was declared and are now far more than double their volume some weeks ago. On the other hand, exports to South America have not increased as rapidly. It is believed, however, that eventually exports to South American countries will prove a tremendous asset to the United States.

Beech Creek, W. Va.—A new and extensive coal operation is being developed in Boone County, on Beech Creek, and it is expected that coal will be taken out in about two months. The new undertaking is that of the Boone County Coal Corporation, J. C. Blair, manager. This firm owns large tracts of land in Boone County and several mines have been operated on lease on its holdings. As soon as the spur track to the mine is completed, work will be begun on the tipple and the town.

Birmingham, Ala.—Representatives of coal-producing companies in the Birmingham district are preparing to go to Panama and South America, and it is expected shortly that a movement will be started that will require many hundred thousand tons of coal to be shipped through Mobile, New Orleans and Pensacola. Brokers in Mobile have notified connections in Birmingham that they are in position to handle any amount of coal, and that the harbor facilities there are in good shape and ready for any and all emergencies.

Cincinnati, Ohio—The Chesapeake & Ohio has filed here its appeal from the judgment against it in favor of the estate of Thomas G. McKell in the sum of $125,000, in the celebrated case which has been pending since 1902. The original suit was for $3,500,000, alleged to be due as damages for the failure of the railway company to carry out the terms of an agreement said to bind it to purchase all the coal mined by McKell in his West Virginia properties. The judgment appealed from was rendered in the third trial of the case.

Harrisburg, Ill.—The Wasson Coal Co. is rapidly becoming a prime factor in the coal production of Illinois. At present, new mines are being opened at Harrisburg, Ill., and Vincennes, Ind. These are of modern construction operated with electrical equipment, such as coal cutters, locomotives and hoisting, pumping and ventilating machinery. Orders for 21 "Type C" locomotives have been recently placed with the Morgan-Gardner Electric Co., this being one of the largest orders for mine locomotives ever placed in Illinois.

Columbus, Ohio—Unless the Hocking Valley Ry. Co. wins its contentions in the Ohio Supreme Court, it will be compelled to pay a penalty of $1000 per day for failure to institute electric service for passengers on the Wellston and Jackson Belt Line. A suit to that effect has been filed by the Ohio Public Utilities Commission in the Jackson courts. The question hinges on the authority of the Commission to designate the kind of service a utility shall render to the public as the Hocking Valley company proposed to start steam service.

Washington, D. C.—The U. S. Bureau of Mines in coöperation with the U. S. Geological Survey, has undertaken comprehensive investigations pertaining to the problem of mine caves and surface support. The immediate work of the mining engineers and geologists will comprise detail studies of the extensive open cut and underground mining operations in southwestern New Mexico. The field investigation will be conducted with special reference to earth pressures and surface subsidence in relation to geological formations and mining conditions, also in relation to the equipment and efficiencies of the large mechanical installations in operation there.

Washington, D. C.—An interesting new exhibit has just been placed in the U. S. National Museum by the Division of Mineral Technology, consisting of a model of a complete by-product coke plant. This model constructed in the Museum shops is in the form of a relief panel 28 ft. long and 7 ft. high on a scale of $^1/_{30}$ actual size, with the different proecsses following in sequence. In connection with this model there is an exhibit showing the development of the coke industry from the earliest crude form of merely burning coal in the open to the present highly complex system of distilation without combustion, preserving and utilizing all the by-products.

Newport News, Va.—Shipments of steam coal from Hampton Roads ports during the month of September were greater than ever before in any single month. They reached the aggregate of 1,271,772 tons, or at the rate of more than 15,000,000 tons yearly. The Norfolk & Western R.R. put 690,348 tons over its piers. The Chesapeake & Ohio followed with 331,098 tons, and the Virginian dumped 250,335 tons. Of the total amount shipped from Hampton Roads, about 300,000 tons, or one-fourth, was exported to foreign countries, South America, the West Indies, Italy and Greece. It is believed that during the past month, Hampton Roads became the greatest coal port in the world, passing Cardiff, which heretofore had lead in coal exports. It is believed also that Hampton Roads will keep its lead and that the coal trade there will become far greater than it is at present.

Cincinnati, Ohio—Opposition has developed to the issue of receivers' certificates of the Cincinnati, Hamilton & Dayton to the amount of nearly $3,000,000 for new rolling stock, in consequence of which receivers Judson Harmon and Rufus Smith have decided to delay the matter until a more opportune time. The Central Trust Co., of New York, indicated its intention of formally protesting to the court against the granting of the issue, on the ground that it would imperil the security of liens held by the company securing bonds for which it is the trustee. The high rate of interest which would have to be paid at present is felt by the receivers to warrant the postponement of the application until a later date. While it is felt that it would be possible to secure the desired rolling stock at very favorable prices, on account of existing conditions, the financial situation would involve excessive interest rates, and nullify this advantage.

Coal Trade Reviews

General Review

Anthracite collieries continue on a full time basis but the demand has slowed up temporarily. Considerable bituminous coal available and current business generally discouraging. Large preponderance of finer sizes still demoralizing the interior markets. England increasing her export shipments.

The spurt in anthracite, caused by some unexpectedly cold weather, has been succeeded by a moderate slowing up in the demand, though conditions are about normal for this period of the year. The buying has only eased off for the time being, pending a return of colder weather and the opening of the fall business. But even now the mines are working up to full time, dealers and wholesalers accumulating all the possible stocks in anticipation of a heavy rush shortly. The difficulty in obtaining ready money has also been a factor tending to restrict buying.

While there is an excellent undertone in the bituminous trade, the current business continues discouraging, and it is generally felt that there will be no renewed activity until the cessation of the European war; prices are only moderately firm, and the agencies are generally short of orders. There is considerable coal at the distributing centers, but a most encouraging feature of the situation is the almost complete absence of the usual customary heavy price cutting that ordinarily marks a depressed situation. The demand for export coal has not been so great, and reports from abroad indicate that England is again resuming her shipments in this trade. Clearances at Tidewater have been fairly regular, but these do not by any means make up for the loss in the internal consumption.

The Pittsburgh market could hardly be more stagnant. All hope of any final rush in the Lake trade has been definitely abandoned, and there is scarcely any demand at all for free coal, while prices are low and exceedingly irregular; the circulars are only nominal and have been entirely abandoned on current business. It is difficult to find any improvement in bituminous coal in any direction, and none can be expected until there is a revival in general manufactures. There is more coal on track, and slack is becoming more difficult to move all the time.

The warm weather has resulted in a distinct slackening up in the domestic business in Ohio, but the production is keeping up fairly well, and the market is not notably changed. Manufacturing operations are still heavily restricted, and with a large surplus of the finer sizes, it is difficult to see how even a long stretch of cold weather will create any general activity.

There is vigorous competition in all directions in the Southern markets, but prices are fairly steady though at somewhat below the customary fall level. Unconfirmed reports of large sales in the export trade has created a hopeful feeling in some sections, but this is probably more than compensated for by the depressing effects of the European war. Prices are fairly steady, but operations are much restricted.

In the Middle Western market an unexpected slump among the high-grade coals has further accentuated the demoralization prevailing in the steam sizes. The customary fall increase in the circular has been put in effect at some points, but so far it is purely nominal. There seems to be no hopes for better prices until the colder weather creates a demand from apartment houses, and there is a more general resumption in industrial circles.

ATLANTIC SEABOARD

BOSTON

Pocahontas and New River demand is light, but no significant change in price. A better tone noted although spot market is not improved. Export inquiry irregular. Georges Creek shipments nearly normal and Pennsylvania grades steady. Stove shortage still a feature in anthracite.

Bituminous—The market on Hampton Roads coals shows no material change. The volume at the piers continues large but clearances have been fairly regular, and there is perhaps a better tone to the situation than for two or three weeks past. Prices less than $2.85 f.o.b. are still being made, but they are not regarded as quite so significant. The agencies are short rather than long of orders for October, but it is hoped that the advancing season and the resumption of full time in some of the mills will show results before the month is over. Shipments on contract show only a slightly better tonnage and the spot market here is conspicuous by its absence. Cargoes on consignment are being absorbed very slowly up the line, and prices for inland delivery cannot be said to be any firmer than a week ago.

Inquiry for export is spasmodic, and shippers are not counting on much more than normal business in that direction for the present. Many of the purchases made in early August have now been filled and new orders on satisfactory terms are not plentiful.

The supply of Georges Creek for this market shows a steady increase and shipments are coming forward almost as regularly as early in the season. The largest part of this tonnage is placed on contracts and there has been no variation in price.

Certain of the more favorably known Pennsylvania grades are having better demand and prices are fairly steady. Clearfields are in ample supply at Philadelphia and New York, but in spite of this there has been no marked concession in price. All-rail there is about a normal movement from all the fields.

Anthracite—The shortage of stove is still the prominent feature of current trade. All the companies have a comfortable margin of orders to work on, and on the other hand, there is no special pressure to get coal forward promptly. With stove coal the desirable size the dealers are confining their orders for the most part to the regular sources of supply, and the various independent houses are, therefore, doing rather less than usual in this territory.

Bituminous prices at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.90@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.15@2.80	2.50@2.90	2.92@3.02	
New York*	2.40@3.10	2.80@3.20	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.85
Boston†				3.60@3.78
Providence†				3.63@3.73

* F.o.b. †On cars.

NEW YORK

Bituminous market is still marking time pending some new developments. Anthracite slowing up moderately but about normal for this period. Mines working full time.

Bituminous—The New York soft-coal market continues dull and uninteresting, so far as new business is concerned. The stocks at Tidewater are only about normal, while there is an entire absence of demurrage coal and the higher grade fuels are rather closely held. The lack of the customary large surplusses, which usually prevail at Tidewater in time of a heavy market, is considered indicative of the excellent condition of the trade, but it is also a significant fact that the operators do not regard the outlook as favorable or they would not be holding the coal back as they are.

On the other hand, there is a decidedly optimistic feeling in trade circles, and there are indications of an excellent undertone. Except in isolated instances, mines seem to be working slightly better, and the movement on contract has picked up some. Of the leading producers, the Berwind White Co. continues the worst sufferers, their operations being curtailed down to from two to four days per week as a result of the more or less complete suspension of the big liners. It is noted, however, that the bunkering demand from the tramp steamers has been unusually heavy recently.

The New York market is not quotably changed, though prices are probably somewhat more steady at the former level as follows: West Virginia steam $2.50@2.60; fair grades Pennsylvania, $2.55@2.65; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

Anthracite—A moderate slowing up in hard coal is noted, though not of important proportions, the trade being very close to normal for this period of the year. The rather sharp spurt of a few weeks ago, caused by some unseasonable

weather, has given way under the influence of the higher temperatures prevailing over the past week, and the trade has settled down into a temporary lethargy, pending the opening up of the customary fall business. One of the features restricting a more general buying is the shortage of money.

In the larger sizes the situation of broken coal is normal as usual, the collieries just making enough of this grade to take care of the demand. Egg coal is the heaviest of any of the domestic sizes, being quoted down to fully 20c. off the circular. Stove coal continues the leader, commanding premiums in all directions, except where sold in connection with some of the heavier grades. Nut coal is normal at the circular. In the smaller sizes, pea is in good demand, though there is plenty available, while rice is moving in fairly good volume, and the buckwheats are notably off. The shipments on egg and nut coal are plentiful, but stove is coming forward very slowly. The collieries are all working full time.

The New York hard coal market is now quotable on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.10	$4.65@5.10	$5.05	$4.60@5.05
Egg	5.35	5.10@5.35	5.30	4.80@5.30
Stove	5.35	5.35@5.45	5.30	5.30@5.40
Chestnut	5.60	5.50@5.60	5.55	5.45@5.55
Pea	3.55	3.45@3.55	3.50	3.40@3.50
Buckwheat	2.80	2.70@2.80	2.50@2.75	2.25@2.75
Rice	2.30	2.10@2.30	2.00@2.25	1.50@2.25
Barley	1.80	1.70@1.80	1.75	1.50@1.75

PHILADELPHIA

Conditions in anthracite market still indicate an improvement. Demand well maintained. Stove leading feature. Bituminous remains inactive, with curtailed operations still in effect.

Anthracite—While the past week has not been conducive to the consumption of the coal, at the same time, there is every indication that the trade is swinging into line for the winter business. All sizes seem to be in fairly good demand, with stove the feature, and still being used as the lever for the movement of other sizes. The steam sizes still continue to bother the operators, who find themselves hard put in some cases, to move it. While the current contracts are absorbing large quantities, at the same time, their requirements will necessarily be limited until the cold weather opens up. Pea coal is essentially a domestic fuel in this market, and very few, if any, buy in larger than one- to two-ton lots. When this class of trade begins to take on coal the congestion of the small sizes is likely to disappear.

In the face of this condition, one hears of few concessions on the small sizes; perhaps 10 to 15c. per ton in occasional cases, but the operators as a whole seem to feel that the time has arrived to strictly uphold the so called circular. Chestnut is also selling off circular, but not to the ruinous extent of the last three or four months.

Prices at Tidewater rule about as follows:

	Circular	Individual
Broken	$4.75	$4.40 @ 4.50
Egg	5.00	5.00
Stove	5.00	5.00 @ 5.10
Chestnut	5.25	4.90 @ 5.00

Bituminous—Very little improvement was noted in this branch of the trade during the past week. While considerable coal is moving on contracts, the outlook for new business is not favorable.

BALTIMORE

Feeling of depression continues. Demand light and prices poor. Anthracite trade on household call fair.

President Willard of the Baltimore & Ohio R.R. has stated that there would be no business resumption of a general nature until after the close of the European war which agrees with the views of many of the coal men. Others, however, are still hopeful that the next few months will see a gradual resumption.

There can be no doubt about dullness in the coal fields of Pennsylvania, Maryland and West Virginia. Curtailments and complete cessations in operations are reported from a a number of districts. Coal was freely offered to the trade in Pennsylvania at from 95c. to $1 for low grades, with best grades at around $1.30. Western Maryland had steam coals on the market around 80 and 85c., and a like figure was quoted for some West Virginia steam fuels. Gas three-quarter was plentiful around 85c., with run-of-mine at 75c. and slack offering down to 30c.

In the face of such a market there was not so much enthusiasm over the fact that export records were broken in September, as might otherwise have been the case. Italy and South America drew more heavily than usual and the export figures jumped to 128,178 tons for the month, the largest on record. Less charters are noted now, however, and it is expected that the exports the present month will drop back around 80,000, or less.

Coastwise movement remains featureless. Vessel bottoms are more than abundant for the domestic, as well as the foreign trade.

Anthracite is reported in fair call for household purposes. Steaming coals are dull.

HAMPTON ROADS

Shipments fair but not so heavy as previous week. Prices practically stationary. Dumpings for September break all previous records. Total for the month, 1,271,772 tons.

Shipments of coal from Hampton Roads during the past week have ben fair although the end of the week there was somewhat of a decline. Foreign shipments have been made to Canal Zone, Vera Cruz, Port of Spain, Rio, Curacao and Kingston with coastwise cargoes going to Boston, Bangor, Providence, Everett, and Jacksonville. The demand for export coal during the last few days has not been so brisk. This is believed to be due to the fact that England is again coming forward with coal for foreign shipment.

Prices remain practically at circular although there have been rumors that some of the small shippers are offering coal at a slight reduction from the circular. There has been a little demand during the week for nut and slack but so far as can be ascertained only a small quantity has been sold. The accumulation of cars on the various railways yards is still somewhat above normal with a fair amount of coal in transit.

All records in coal dumping over the tidewater piers were broken during the month of September when a total of 1,271,772 tons were dumped over the Lambert's Point, Sewalls Point and Newport News piers. Of the total quantity dumped 690,348 tons went over the piers of the Norfolk & Western, 331,089 tons over the Chesapeake & Ohio and 250,335 tons over the Virginia Ry. pier at Sewalls Point. As will be noted the Norfolk & Western dumped 108,924 tons more than the Chesapeake & Ohio and Virginia combined and while both the Norfolk & Western and the Chesapeake & Ohio show a decided increase over last month's figures, the Virginian shows a falling off.

COAL CHARTERS

The "Journal of Commerce" reports chartering as follows: As has been the case for some time past, trading was largely for transatlantic account, and a moderate demand continues to come from the same sources for boats for October loading. In all other trades, including West India, South America, China, Japan and Australia, freights are exceedingly scarce for either prompt or forward loading. There is a moderate supply of boats available for early delivery, but they offer sparingly at the rates indicated by charterers, owners ideas being somewhat above the basis of recent fixtures. The sailing vessel market shows no indication of improvement, either as regards the general demand or the rates bid, and only a limited general business was reported in chartering. Tonnage of various kinds is quite plentiful, and the general tendency of rates favors charterers.

Coal charters have been reported as follows:

Vessel	Nationality	From	To	Tons	Rate
Auchenblae	British	Baltimore	Cienfuegos	2500	
Aero	Norwegian	Philadelphia	Cienfuegos	1092	
Fanny C. Bowen		Philadelphia	Calais		$1.10
Courtney C. Houck		Baltimore	Tampa	1357	
Isabel B. Wiley		Philadelphia	Point-a-Pitre	611	
Republic		Philadelphia	Point-a-Pitre	680	
Francis M.		Baltimore	Key West	1096	1.25
Augustus Welt		Baltimore	Mayport	1111	
Maud Palmer		Baltimore	San Juan P. R.	1485	
Henry W. Cramp		Baltimore	Mayport	1448	
Brin P. Pendleton		Philadelphia	Calais	821	
John B. Manning		Philadelphia	(to the sound)	955	0.60
Ben Nevis	British	Baltimore	Genoa	2525	

Note—Steamers are indicated by **bold face** type, all others being schooners.

COKE

CONNELLSVILLE

Coke market stagnant, except for sale 10,000 tons prompt furnace at about $1.65. No inquiry. Shipments somewhat decreased.

The only activity in furnace coke for some time past was the sale about a week ago of 10,000 tons for October shipment to a Buffalo consumer, the purchase being necessitated in part by the withdrawal of Dunbar byproduct coke, now to be used locally as one of the Dunbar furnaces is being blown in. The price is believed to have been about $1.65 at ovens. The whole coke market is utterly stagnant, consumers not evincing enough interest to develop any quotations to speak

of from producers. We quote as nominally representing the apparent market level: Prompt furnace, $1.65; contract furnace, $1.75; prompt foundry, $2.25; contract foundry, $2.25, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Sept. 26 at 247,221 tons, an increase of 3526 tons, and shipments at 248,063 tons, a decrease of 8474 tons, production and shipments about balancing.

BUFFALO

The reports from the coke trade continue unfavorable. Shippers are unable to interest consumers beyond the line of their immediate wants, so that the prices are constantly sluggish and in some grades little more than nominal. Quotations remain on the basis of $4.25 for best 72-hr. Connellsville foundry and $3.30 for stock coke.

BIRMINGHAM

Both furnace and foundry coke are very quiet, with no improvement in sight.

LAKE MARKETS

PITTSBURGH

Market completely stagnant and prices still more irregular, even $1 being occasionally shaded for mine-run. Lake shipments poor. Mining at 50% of capacity.

The local coal market is about as stagnant as it could well be. There is hardly any demand for free coal, and none at all for contract. Prices are extremely irregular, and on some divisions even $1 a ton is not minimum for mine-run. For the best Pittsburgh gas coal, however, $1.10 would probably have to be paid, and possibly $1.15. Slack is offered at all prices, in a few instances at less than 50c. Lake shipments have declined a trifle in the past week or two, but not much. Practically all hope has now been abandoned that there will be any spurt in shipments, as it is already near the end of the season, and the entire Lake movement is likely to show a decrease of more rather than less than 25% from the record tonnage of last season.

There begins to be considerable doubt whether any new circular prices will be announced. The old circular prices, of a year ago, have been entirely lost sight of for months when it came to naming actual quotations against inquiries, but as a matter of history they are repeated in our report: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.50, per ton at mine, Pittsburgh district. Mining operations are about 50% of capacity.

BUFFALO

Considerable coal on track. Slack difficult to move. Quiet all through the bituminous trade. Disposition to ship in excess of orders. Good anthracite trade in spite of warm weather.

Bituminous—There is more coal on track than is good for the trade. Several jobbers confess to large amounts of coal for which they blame the mines. The supply of slack is increasing all the time and sales are made at a sacrifice.

There does not appear to be any improvement anywhere in bituminous; the salesmen keep everybody so far overstocked that it is impossible for a really genuine demand to exist anywhere and this will doubtless continue till there is a big revival in factory work. If Europe must buy soon there should be some start in that direction, but it is all a matter of prediction so far. One difficulty with the trade is the refusal of the railroads to buy.

But in spite of these adverse conditions there are shippers and jobbers here who claim that their business is growing steadily, month by month and is larger now than it was a year ago; this would seem to indicate that there is activity somewhere. The change in the bituminous trade is mainly in slack, which goes begging everywhere. Other quotations remain on the basis of $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.15 for slack. Allegheny Valley sizes are about 25c. less.

Anthracite—There is an improvement in practically everything. Egg, which was dull for sometime, is stronger and pea has moved more actively of late. Stove and chestnut are strong. While there has been a falling off in Lake shipments of late that is merely on account of the excess amount on the Upper-Lake docks. Trade is good there, but there was too much carried over from last winter.

The local anthracite trade is much better than the recent long run of warm weather would seem to warrant. Should it come really cool now the demand would increase very rapidly. The spurt in August on account of the war has about been discounted, so that the future looks good. The railline trade is reported brisk.

Lake shipments for the week were 124,750 tons, for September, 428,426 tons and for the season to Oct. 1, 3,156,781 tons. The September decrease is about 20% from the same month last season and it is doubtful if there will be room enough developed on the Upper Lake docks to lessen the falling off. The amount shipped last season to October was 3,840,936 tons.

TOLEDO

Nearly a million and a half tons of coal passed through Toledo during September. Ore tonnage light. Domestic coal affected by weather conditions. Steam grades a little stronger.

The changing weather conditions have kept the coal dealers in a most uncertain position. The domestic market here is hinging entirely on the weather. The steam market is showing a little more strength but the demand has not been up to normal. The Lake movement continues fairly active and the reports from the customs office shows that 1,420,044 tons of coal passed through this port during the month of September, of which 458,896 tons were for Canadian ports. The ore tonnage was extremely light amounting to but 66,580 tons for the entire month of September. Prices as quoted on the Toledo market follows:

	Hacking Valley	Cambridge	Pomeray	Massillon	W. Va. Splint	Pocahontas
Lump	.....	.....	.....	$2.50	.....	$2.25
Lump	.....	.....	.....	2.50	.....	2.25
Re-screened Lump	$1.70	.....	$1.75	.....	.....	....
Domestic Lump	1.60	.....	1.60	.....	$1.60	
1¼ Lump	.....	$1.40				
¾ Lump	.....	1.20				
Egg	1.25	.....	1.35	.....	1.15	2.25
4-in. Black	.....	.....	.....	.....	1.75	
Nut	1.15	.....	1.25			
Washed Nut	.....	.....	.....	2.50		

COLUMBUS

Trade quiet because of the continual warm weather. Steam business is still slow while Lake trade is active. Prices unchanged.

With continued warm weather there is a distinct slackening in the domestic trade in Ohio markets. This has not affected the situation to any extent as production is keeping up fairly well, but on the whole the tone of the market is not as satisfatcory as formerly. No new circular was issued Oct. 1, and it is doubtful if any change in prices will be made before Nov. 1.

The domestic demand, which has been the backbone of the trade, is quiet all along the line. Stocking up on the part of private consumers is not as active as formerly and dealers have been cancelling orders or deferring shipment. Their stocks are sufficiently large to take care of present needs. Retail prices have not suffered by the slump and cutting among dealers has not been resorted to at all.

The Lake trade is still fairly active as the demand from the Northwest continues good. Docks of the Upper Lake ports are generally free from congestion. Chartering of boats is going on actively and the Lake movement will probably continue until the close of navigation. Steam business continues dull in every particular and there is no immediate hope for improvement. Manufacturing is still slow and purchasing agents are loath to lay in surplus supplies. Much of the buying for steam purposes is on the open market although a number of steam contracts have been concluded within the past few weeks.

The market for fine coal is still weak but a number of shippers profess to see an improvement in this branch of the business. Production in Ohio fields has been fairly good under the bad conditions. Pomeroy Bend reports a normal output and the same is true of certain districts of the Hocking Valley. Jackson and Crooksville have produced about 80% of the average. All mines are idle in eastern Ohio.

Prices in the Ohio fields are:

	Hocking Valley	Pomeroy	Kanawha
Re-screened lump	$1.70	$1.75	
Inch and a quarter	1.60	1.60	$1.50
Three-quarter inch	1.45	1.45	1.45
Nut	1.15	1.40	1.15
Mine-run	1.15	1.15	1.15
Nut, pea and slack	0.30	0.35	0.30
Coarse slack	0.20	0.25	0.20

CLEVELAND

With receipts of 150 cars over Sunday the Cleveland market is demoralized. Prices are off 10 to 15c. and the Lake trade is rapidly slowing down.

Hocking coals have been dumped into northern Ohio steam markets until spot prices have been forced down

10 to 15c. and though shipping prices are nominally the same as a week ago, 5 to 10c. a ton less would be acceptable for fine coal. Panhandle slack was offered recently at 45c. at the mines, $1.45 Cleveland, with other fine coals at very nearly the same.

Lake front coal docks are going on a single day shift and by the middle of the month only one or two docks will be working day and night. A number of ships have been ordered laid up this week and by the middle of the month fully 30 vessels will be out of commission for the season. The Upper Lake docks are loaded to capacity and, even though space were found later in the season, the supplies of coal are sufficiently large to carry the dealers and trade over until next season when new coal will be available.

No. 8 field will not ship any Lake coal this season. It is now a question whether any of this coal for commercial purposes will be produced this winter. Operators are discussing Apr. 1, 1915, as the probable date for resuming mining.

In the Bergholz field two mines were closed last Saturday because the coal produced under the mine-run contract was too fine and dirty. At another mine it was necessary to fine the men for allowing too much extraneous matter to get into the coal. At a third property an attempt was made to suspend two miners because of the slate in the coal, but a strike followed and the operator was forced to take back the men.

Prices for current shipment are as follows:

	Pocahontas	Youghiogheny	Bergholz	Fairmount	W. Va. No. 8
Lump	$3.75				
Lump, 6 in.			$2.45		
Egg	3.75				
Egg, 6 in.			2.10		
Lump, 1¼ in.		2.40	2.25		
Lump, ¾ in.		2.30	2.10	2.00	2.05
Mine run	2.75	2.15	1.95	1.90	1.95
Slack	2.40	1.50	1.45@1.50	1.50	1.50

CINCINNATI

Light demand for screenings continues the main feature. Movement of the domestic grades slow though demand is good. No immediate relief in sight.

Plants operating on a curtailed basis will buy little coal until cold weather compels them to use more for heating purposes. But even cold weather will not cause the factories to open up, nor furnish more business to any industry and as the industrial depression is the principal cause of the slow steam market, some other stimulant must be looked for. Reports of reviving export trade indicate the probability of greater activity among local manufacturing plants than has been the case for some time which should help the situation materially.

The domestic movement is still good, both with the operators and the retail trade. The season is now late enough to make it easy for consumers to appreciate the closeness of cold weather, and deliveries are consequently being made in good volume. Prices for the prepared grades are normal, but this can hardly be said for screenings or any other grade of steam coal.

SOUTHERN

BIRMINGHAM

Market rather quiet. Many rumors regarding large sales, but no confirmation.

This week has brought out no decided change, either on steam or domestic coal. The local demand for steam coal is quiet, and lump coal is moving only in small quantities. There have been reports of several large sales of Alabama coal to foreign countries this past week, one of which was 1,000,000 tons to Greece, but they cannot be confirmed. Blacksmith coal is in a satisfactory condition. Sales of pig iron are light.

LOUISVILLE

Vigorous competition in all directions. Prices fairly steady though at less than the customary fall schedule. Operations restricted.

The domestic movement is holding up fairly well but the general activity is sharply reduced from what it normally is at this time of year. The effect of the war in Europe is more depressing if anything.

Salesmen are active in all sections and competition is vigorous. It was expected that some business might develop on the Eastern coast but the companies have found competition as keen there as closer at home. As a rule there has not been much slashing of prices, though these have not been advanced as much as usual this fall. Occasionally contracts are rewritten on the old basis though a number have been bid in by new companies at lower figures. This applies to steam coals only.

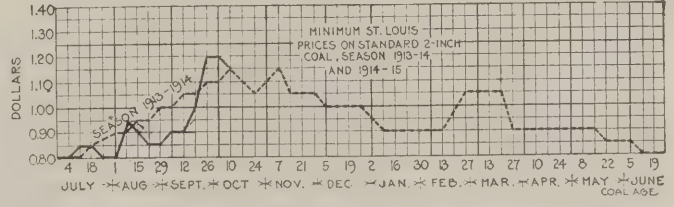
In Southeastern Kentucky where most of the mines resumed full-time operations toward the close of the summer, there has been a return to the three-day a week basis again. Occasionally full time operations are the rule where operators are particularly well situated.

Block coals range widely, from $1.75 to $2.25 a ton, f.o.b. mines, with egg sizes at from $1.25 to $1.50. Nut and slack of the best grade is plentiful at from 50 to 60c. and the lower grades from 25c. down to nothing, some mines permitting it to be hauled away free. The Western Kentucky screenings are hard to sell at any price.

MIDDLE WESTERN

INDIANAPOLIS

Weather against trade and mine schedules are reduced. Screenings situation about the poorest ever known. Domestic grades moving fairly well. Some Oct. 1 advances at mines.



Mid fall weather is having an adverse effect on the coal industry, making current demands comparatively small. The demand for domestic grades continues fair, mainly because of anticipatory buying. The screenings situation is becoming worse than it was last year. It seems that 40c. is regarded as a good price in the open market. Mines are compelled to sacrifice them in order to be able to produce domestic coal to fill orders.

Lump coal sells at $1.75 at the mines and mine-run, No. 4, at $1.20. The mine schedules are somewhat reduced and cars are now in ample supply. Railroad buying has not improved notwithstanding the exports of wheat and flour are the largest in the history of the trade. Buying by industrial plants is not up to normal for the season. Prices were raised Oct. 1 at some of the mines, 10 to 15c., probably those that had not made the similar advance noted a week or two before. This is on domestic grades, in order to get a fair average when screenings are sacrificed, and also because it has been the custom to shove the price up Oct. 1.

ST. LOUIS

Heaviness in the steam sizes still the controlling factor in the market. Some mines are caught up on domestic orders.

An unlooked for depression in the demand for high-grade coal caused a slump about the first of the month, and this, together with the demoralized condition of the steam market, brought about a deplorable condition. Several of the mines in Williamson and Franklin County, however, are well sold up on lump and egg, and are behind in their orders. This is chiefly on account of their inability to move the steam sizes, which have been accumulating on the tracks and has resulted in the railroads refusing to give these mines equipment for their lump and egg orders.

Other mines, more fortunate in moving their smaller sizes, are now caught up on the lump and egg orders and are finding it somewhat hard to get a fair price for those sizes. The steam market shows no improvement. The washed market on Nos. 1 and 2 is picking up some, but the other sizes are dull. In the Standard field screenings are still given away for the freight, and the top of the market is about 10 to 15c. on exceptionally good coal. Even with this condition, Standard 2-in. lump can be bought for as low as $1.05 in some cases, although the circular is $1.10 to $1.15.

	Williamson and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump			$1.25	$1.10@1.15	$1.15
3-in. lump			1.40		
6-in. lump	$1.60@1.85		1.50	1.25@1.35	1.40
Lump and egg	1.85@2.15	$2.25			1.35
No. 1 nut	1.25@1.35			0.75@0.80	
Screenings	0.25@0.35		0.80@0.85	0.05	0.20
Mine-run	1.05@1.10			0.75@0.80	
No. 1 washed nut	1.55@1.65	2.25	1.50		
No. 2 washed nut	1.30@1.35		1.35		
No. 3 washed nut	1.10@1.15				
No. 4 washed nut	1.00@1.05

KANSAS CITY

Market slow as a result of the warm weather. Gas supply will not be plentiful this winter. Collections slow.

A long series of warm days in Kansas City has retarded the usual starting of fires, and the ordering of coal. The steam plants have not generally begun operations yet, and some that started the furnaces in September have drawn the fires. The retail trade is also largely waiting, though there are reports that promises of higher retail prices in October stimulated orders in nearby towns. The retail prices have not yet been advanced here. Later reports indicate that the improvements necessary to provide plenty of gas probably cannot be made in time for the cold weather now approaching. Collections are difficult, and it is suggested that this situation is also a deterrent on coal orders, retail customers postponing purchases as long as possible.

PORTLAND, ORE.

No further advance in prices anticipated. Car shortage not yet felt. Business brisk owing to increase in wood prices.

Coal dealers here are doing an active business and are having no trouble now in getting supplies from the mines or making deliveries. In fact the business is running smoother than for a long time and on a very satisfactory basis. There was some suspicion that prices would advance on Oct. 1 but dealers say this will not be necessary and no advances are now expected for some time unless it should be on lower grade coals. The railroads have managed to furnish all the cars required, and orders have been filled quite promptly.

Coal Contracts Pending

Contract No. 1—Columbus, Ohio—The Ruggery Building is in the market for 300 tons of West Virginia slack coal. Shipments are to be made at the rate of 25 tons per day, beginning Nov. 1, delivery to be made at Columbus, Ohio. All communications should be addressed to J. A. Shahan, 60 Ruggery Building, Columbus, Ohio.

Contract No. 2—Norfolk, Va.—The United States Government is in the market for 2000 tons of bituminous coal. All communications should be addressed to E. Eveleth Winslow, Lieutenant Colonel of Engineers, United States Engineer Office, Norfolk, Va.

PRODUCTION AND TRANSPORTATION STATISTICS

ANTHRACITE SHIPMENTS

Anthracite shipments for September and the first nine months of this year and last year were as follows:

	September		9 Months	
	1914	1913	1914	1913
Phila. & Reading	1,101,296	888,060	8,869,552	9,504,550
Lehigh Valley	1,290,327	1,031,376	9,550,799	9,671,928
Cent. R.R. N.J.	824,604	788,038	6,560,049	6,795,406

FOREIGN MARKETS

GREAT BRITAIN

Sept. 25—Inquiries are on a limited scale, while supplies of all qualities are plentiful. Prices are weaker in consequence and are approximately as follows:

Best Welsh steam	$4.08@5.28	Best Mountmouthshires	$4.14@4.26
Best seconds	4.44@4.68	Seconds	3.96@4.08
Seconds	4.26@4.38	Best Cardiff small	1.80@1.92
Best dry coals	4.44@4.68	Seconds	1.20@1.56

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both net, exclusive of wharfage, and for cash payment.

Freights—The demand for tonnage is not so active but rates are about unchanged and are approximately as follows:

Gibraltar	$1.68	Aden	$2.22
Malta	1.68	Colombo	2.28
Marseilles	1.64	Sabang	2.28
Algiers	1.44	Singapore	2.46
Genoa, Savona	1.74	Las Palmas	1.80
Naples	1.74	St. Vincent	1.92
Venice, Ancona	1.86	Rio Janeiro	3.18
Alexandria	1.92	Monte Video	3.06
Port Said	1.86	Buenos Ayres	3.30

The London coal trade has at last begun to show signs of returning activity. The increasing export trade has given confidence to buyers, and the volume of trade doing is increasing. The delivery trade, however, continues weak, but factors and merchants are buying more freely for stock. Manufacturing qualities are in good demand, and kitchen coal and bakers' nuts are also moving better. Gas coals, although very low in price, are improving, but slacks and small nuts are still weak and plentiful. The seaborne market shows no change.

The coal markets in the provinces have benefited by the cooler weather which has prevailed during the week. On the other hand, too, there is an increasing enquiry from friendly and neutral countries. Financial conditions are still prejudical to business, and this disadvantage has been severely felt at Cardiff, where little new business has taken place, the market in general being dull and void of special feature. On the Tyne, whilst the volume of business does not appear to have greatly expanded, the undertone of the market is good. The West Yorkshire market has become depressed, but that in the South shows a slight improvement; the reduction of output and a fair demand has served the purpose of steadying the market. In Lancashire the house coal trade has improved owing to the colder weather. The Scottish coal trade may be said to have changed little, and remains very quiet.

It is officially announced that on Nov. 4 the general moratorium will be terminated.

The South Metropolitan Gas Company has increased the price of its gas owing to the continued high price of coal.

It is announced that the Portuguese railway contract for steam coal has come to this country. This is the first coal contract which has been diverted from Germany by the war.—"The Colliery Guardian."

COAL AGE

Vol. 6 NEW YORK, OCTOBER 17, 1914 No. 16

"Tom, I want you to clean up your moral record before I put you on as trackboss in this mine," said a mine foreman to an applicant for a job. He continued, "I know you have a pretty good name as a worker, but I know further that if you had a stronger moral reputation your control over men under you would be better, and your efficiency and usefulness to this company would be greater. You know as well as I do where you are weak, so we need not dwell on that matter. And I want you to understand that I'm not preaching, for I have no right to do that; I am only talking sense based on experience".

"I know what you mean all right," said the other, "but I'm not sure I can do what you want me to." "Well, you'll not get your job until you show me that you're going to try and you'll not hold your job a minute after you stop trying," replied the foreman.

This conversation took place recently at one of the large bituminous mines of western Pennsylvania. The mine foreman in question is a man whose past is none too clear, and he knows it. But he knows, also, that from the time he resolved some ten years ago to clean up his record he has been a different man, rising rather slowly perhaps, but consistently, to a point where he now has attained the respect of all the people in the community in which he lives. Moreover, he has won a reputation as an excellent mine foreman, alive and hustling, getting results for his company and a square deal for his men.

His method of dealing with the applicant for a job was of the right sort. When a man of ability comes along, there is no use in turning one's back on him if he happens to be morally weak. On the other hand, it would be equally foolish to utterly disregard the man's reputation, and thereby indirectly encourage him in his weakness. The thing to do with such a one is to help him to help himself, and the best way to do it is to make his helping himself a part of his job. That this pays must be perfectly clear when one stops to reflect that it is well nigh impossible for a man to strive to make a clean name for himself without at the same time raising the quality of his work.

Wherever the morality of a community is good, then it is almost certain that the physical conditions of the town and mine are clean, and that due attention is paid to questions of sanitation. It is a great deal easier and more practicable for a mine foreman to insist upon moral cleanliness on the part of his men if he has his mine in clean condition, if his roads are free from dust and rock, and if all low places in the entries are drained to prevent their becoming sumps.

An outside foreman, likewise, can do much to promote moral cleanliness by paying scrupulous attention to the physical condition of the plant under his charge. If the grounds around the various buildings are slovenly and dirty, the chances are that the outside foreman and his men are correspondingly careless of their own cleanliness. If, on the other hand, the office is surrounded by well-kept grounds, the shops and power-house cleared both inside and outside of oily waste and other refuse, then it is evident that there is an efficient foreman in charge, and there is little doubt but that his organization is well aware of the advantages of cleanliness.

After Safety First, we ought to have Sanitation Second, and sanitation ought to be both moral and physical.

Why This Persecution of Coal Men?

A RECENT edition of the New York American ran a large cartoon by Windsor McCay on its editorial page scolding coal men generally and holding them up to view as robbers and oppressors of the human race. The picture was headed, "The Same Old Hold-Up Game," and showed a portly gentlemen known as the coal trust wrapped in furs standing out in a blizzard, going through the pockets of an unfortunate shivering citizen. Underneath the cartoon the editor had written, "The Coal Trust is counting on winter to tie the consumer hand and foot while he goes through his pockets. It is the usual game and is worked every time cold weather threatens, and cold weather threatens every year."

Just why the metropolitan press persists in rebuking the coal industry at every opportunity we do not comprehend. Coal is produced under the most hazardous conditions. The men who mine the product are among the highest paid workmen in this country, ranking third in the great coal state of Pennsylvania. There isn't one mining company in ten that has averaged fair interest on its investment during the past decade. Coal prices are more stable year in and year out than the prices of any other widely-used commodity. Government officials who have collected facts support all these contentions.

Then why must the coal producer engaged in an industry filled with lurking dangers be subjected to continual criticism. The fuel industry in this country is second only to agriculture, employing in all departments considerably more than a million men. Is this business of mining a separate industry standing alone and not linked to the national prosperity? Are we outcasts just because we lead all others in "Safety" and "Welfare" work? Must we be marked as a criminal class just because we do not forever shout our virtues from the housetops?

The coal business will bear the light of day and we trust sometime, somehow, somewhere, a great newspaper editor will send an honest man to our coal fields and have him search out the truth and write it as he sees it. The European war leaves 5,000,000 bales of cotton in the hands of our southern planters, and everyone, coal men included, is asked by Mr. Hearst, to turn to and lend a helping hand. This is all as it should be and we applaud the worthy intent back of the move; but, cotton growing does not encompass all the industrial life of America, and there are other lines that at least should have encouragement if not material help.

We pay 5c. for 10 roasted chestnuts on a New York street. A good looking rosy-cheeked apple costs us another 5c. Potatoes are 5c. a quart, etc., etc., yet we hurl invective at the coal man who sells us his product at the same old price whether times are good or bad. Once sold the coal is gone forever. The mine owner can't grow any more. In 20 years his property, houses and all, is without value. Apples, potatoes, chestnuts and a hundred other things to eat are rotting on all our farms, and next year the ground will grow more, and in 20 years the farm will still be there producing as usual, probably enhanced in value.

Mr. Hearst, turn your attention to the retail dealers who sell the things we eat and who have the audacity to insist that the so-called free markets of Manhattan be closed in order that the small dealers can charge whatever they please for the things we must have to subsist on.

The coal industry is a worthy business engaged in by the strong daring men of our race. Close our mines and every wheel from New York to San Francisco will stand still. Compared with such a calamity, the present European war's effect on our business life is but a midsummer zephyr. Therefore, be fair, and let an occasional shaft of generous encouragement supplant the unwarranted rays of bitter malevolence that are so often turned on us.

Explosion at Mulga in Alabama

By Henry S. Geismer*

SYNOPSIS—The Mulga mine again explodes, this time killing 16 men. Hirsch electric lamps play an important part in the rescue work. A negro miner saves 9 of his comrades. The safety precautions adopted by the owners at Mulga were elaborate and seemingly complete.

A gas explosion occurred at the Mulga mine of the Woodward Iron Company at Mulga, Alabama, at about 9 a.m., Oct. 5, killing 16 men and injuring 11 others. Of the killed, 8 were white and 8 were negroes. Among the injured, it is possible that two are fatally injured.

General View of Surface Plant at the Mulga Mine

The explosion occurred either in the eighth or ninth heading off the north haulage. All of the men killed were found lying along these two entries with the exception of two men who were found inside the neck of No. 18 room on the eighth right. Several of the men were killed outright, but most of them were apparently overcome by afterdamp.

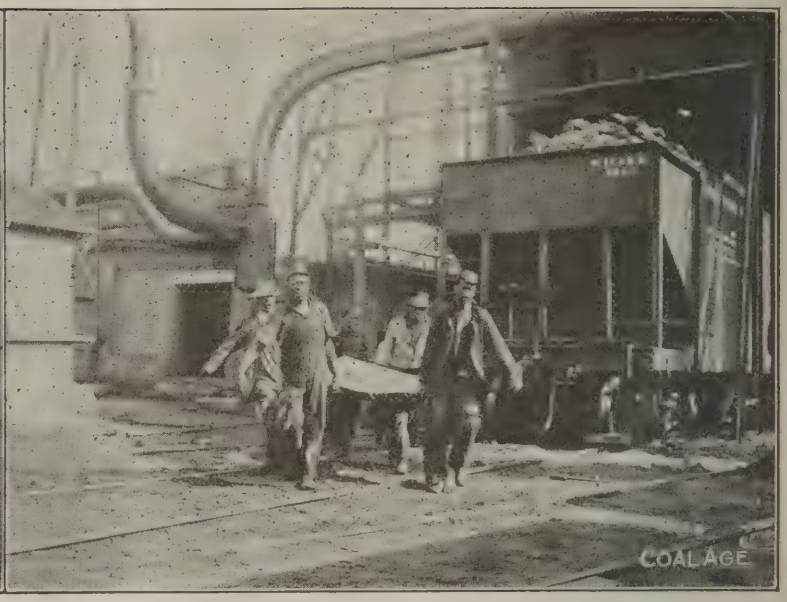
The miners use open lamps in the mine and as several rooms were marked up by the fireboss in his early-morning inspection, as containing gas, it is possible that the gas was ignited by a miner's lamp. The explosion was not felt in any of the entries except the eight and ninth, which are close together, the seam being worked on the double-entry system and men in other parts of the mine did not even know that an explosion had occurred.

The number of men in these two entries was above normal on the day of the explosion because there happened to be a trackman and two helpers also a rockman and one helper working in these entries; all of these men were killed. Most of the men who worked in the eighth and ninth right headings were either killed or injured.

The men go to work between the hours of 6 and 7 a.m., the entrance gates being locked at 7 a.m. As the entries where the explosion occurred are only about three-quarters of a mile from the hoisting shaft, it would seem that all of the men must have been at work more than an hour when the explosion occurred.

The Fans Were Not Injured

The explosion did not affect either one of the fans nor was the mine damaged at all, so rescue work was started immediately. Helmets from the U. S. Bureau of Mines rescue car, under charge of E. B. Sutton, arrived early in the afternoon and from then on the work of exploring the two headings was carried on rapidly. Before the arrival of the helmets, eight bodies had been recovered.



*Birmingham, Ala.

Relatives and Friends of Victims Assembled at Shaft Just after the Explosion Occurred

One of the Rescue Party

Carrying Bodies to the Morgue

The last body was taken from the mine about noon of Oct. 6.

On the morning of the explosion, M. W. Campbell, a demonstrator for the Hirsch Electric Mine Lamp Company, of Philadelphia, Penn., had equipped eight miners with electric lamps to demonstrate their value. One of these lamps was in use in the ninth right heading and another was in use in the tenth right heading further inside. Neither one of these lamps was extinguished by the explosion and this fact undoubtedly assisted in the work of rescue, as there were no safety lamps in the immediate vicinity of the explosion and time would have been lost.

The Mine Is Well Equipped

The mine is one of the best equipped mines in the South; coal is cut by electric machines and hauled by electric locomotives. Two fans are in use, either one of which has considerable excess capacity over total requirements and both of them are arranged for steam and electric drive. A modern and efficient sprinkling system has been installed throughout the mine and all of the rooms, as well as the entries, are constantly sprayed. No dust is allowed to accumulate and the system of inspection is of the best. The coal is shot by shotfirers after all the men leave the mine and safety powder is used.

For some months after the mine was opened, safety lamps were used exclusively as a considerable quantity of gas was always present, but after perfecting the ventilating system and greatly increasing the quantity of air, the presence of gas was rarely detected and by a careful inspection with firebosses, all danger from this source had been considered as eliminated.

The mine has always generated dust, but it is not allowed to accumulate, and with the splendid system of sprinkling in vogue, danger from this source has been eliminated as far as possible. The recent explosion seems to bear testimony to the effectiveness of the manner of dealing with the dust problem. All of the headings had visible moisture on the top, sides and bottom.

The mine is on the well known Pratt seam and is reached through two 3-compartment shafts 220 ft. deep. One is used for hoisting and the other for ventilation, but it is planned to use both for hoisting in the near future. The seam is nearly level and has a thickness of about 4 ft. 6 in. The mine is located on the A. B. & A. also the Ensley Southern Railroad.

All of the officials of the Woodward Iron Company, including A. H. Woodward, vice-president; B. E. Purser, general superintendent of mines; J. D. Dalrymple, superintendent; S. L. Morrow, chief engineer, and Tom Black, mine foreman, remained at the scene of the explosion until all of the bodies had been recovered. The commissary was thrown open to the rescuers and with the as-

Colored School at Dolomite Mine of the Woodward Iron Company

sistance of Mrs. S. R. Stevenson and Mrs. J. E. Edwards, no one in attendance at the scene of the disaster whether working or not, was allowed to go hungry.

Chief Mine Inspector, C. H. Nesbit and four of the associate State Mine Inspectors, Tom H. Tinney, W. P. Smith, Frank Hillman and David Kelso, remained on hand to render any assistance possible. Several employees of the T. C. I. & R. R. Co. under the direction of Gen. Supt. John F. Meager also rendered valuable assistance as they were all experienced helmet men.

The hero of the day seems to have been Harry Jackson, a colored miner. He was one of the men wearing a Hirsch electric lamp and after the explosion he went in the ninth right and lead out 9 miners who were in the dark almost overcome with afterdamp. And Jackson was not the only colored man whose actions bordered on the

PLAYGROUNDS AT A WOODWARD IRON CO. MINE

heroic. All during the day and night whenever volunteers were called for, the colored men always volunteered in numbers beyond the requirements and they never hesitated for a moment in carrying out any instructions given them.

With each added explosion it becomes evident that the state is well supplied with trained rescue men and the value of their services is coming more and more to be realized.

The men who came to the top after the explosion, were so badly excited that many of them failed to hang up their checks and so some confusion was experienced in trying to account for all of the men supposed to be at work.

The average daily output of the mine is about 1250 tons and approximately 325 men are employed. On the day of the explosion 284 men were inside. The output comes from two main haulageways starting at the shafts and running at right angles. The miners are about evenly divided between the two territories. All of the bodies will be buried at Woodward.

The complete list of the dead is as follows:

WHITES	
Edward King, aged about 40 years, married	John Polinsky, foreigner
Charles Campbell, aged about 30 years, married.	John Kooternick, foreigner
W. M. Long, aged about 28 years, married.	NEGROES

	Scot Garrett
	Warren Wheeler
	Hamp Swansey
	Carey Howard

The life of H. E. Williams, one of the injured miners is despaired of.

Extracts from a Superintendent's Diary

We mining superintendents are fated to view death in various forms and from many angles. And because we are so often made to feel the mystery of death, we speculate much on the mystery of life.

All of the roads to death wind through our experiences, and with but little imagination, they often seem the roads to life also.

Explosions, fights, strikes and endless accidents, all exact their toll from our community, and the circumstances of death vary from the whimsical to the sublime.

Today we may find ourselves following the frightfully maimed body of a miner (who was all but killed instantly by a fall of rock in his working place) on its journey from the pit mouth to his home; and before we can find courage to leave him alone with his dazed and weeping wife, the victim expires. A few motions of the hands, several incoherent words, a smile and the separation is complete for eternity. His last wish, his last thoughts swallowed up with the great mystery of death.

Tomorrow we may be summoned to a dying one who, instead of parting from us with motions and signs that only the Good God can interpret, lingers long, talks freely and impresses us with the mystery of life rather than the mystery of death. He is a man who has made but a dim mark in the world during his lifetime. Always he has had a grim struggle to keep body and soul together and has only succeeded in that by denying himself of every comfort and pleasure. He tells us that he is ready to die, although he has enjoyed life immensely, and we marvel.

After his death it transpires that in spite of his straitened circumstances, he was constantly assisting women and children through endless complications and tragedies. A little sympathy here, a kind word there, or perhaps just the right advice to a family on the verge of annihilation has caused them to take courage and fight their way to a brighter future. The death of the guiding one opens the lips of the guided and for the first time the camp learns of the things he achieved in secrecy.

He considered his life futile and yet his memory will be honored for a generation in homes where his influence came as a blessing.

Nor is the passing away of those who have fared better according to worldly standards always without surprises. We may have known them as liberal and public spirited and yet when they come to die they insist that they are afraid of the hereafter because they have had so little thought of anything except self. And when all of the facts come to light, as they generally do, it appears that their going away has not affected vitally the current of a single life, and outside of their immediate family they will soon be entirely forgotten. When their gifts were solicited and accepted, there seemed to exist a crying need for them, but now in looking back we realize that somehow we must have been mistaken in analyzing the need or in applying the relief.

And so we gradually learn to admit the futility of trying to judge men by any standards at our command as well as the uncertainty of tabulating successes by what people seem to have accomplished. And although all of our philosophizing does not clear up any of the mysteries of life, still it helps us to accept things without constantly questioning God's purposes.

Dr. McHenry's Chart

The American Mine Safety Association expects to distribute a series of Safety Circulars. The first of these contains the illustration accompanying this article and shows the relative frequency of injuries received in the nine-year period between Mar. 11, 1905 and June 20,

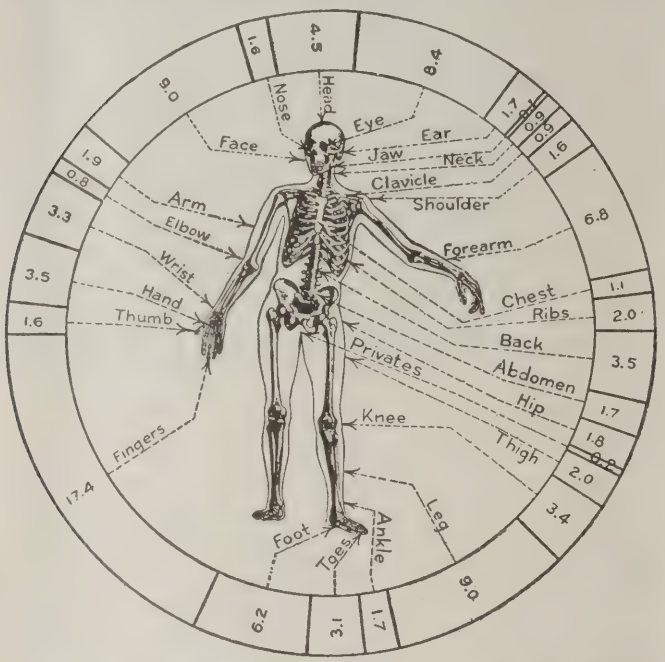

Chart Showing Distribution of Mine Injuries

1914 at a certain bituminous coal mining operation. In all, 6908 injuries have been recorded and tabulated.

The chart was prepared by Dr. Ralph F. McHenry, chief surgeon of the Penn-Mary Coal Co., of Heilwood, Penn. The percentage of reduction of non-fatal injuries in the nine-year period is 49.81. Fatal injuries have been reduced 40 per cent. It is evident that the first-aid work has been not only a cure but a preventive of accident.

The injuries may be further divided as follows: Fractures, 4.4 per cent.; lacerations, 38.2 per cent; contusions, 33.5 per cent.; burns 5.2 per cent.; punctures, 18.56 per cent.; dislocations, 0.23 per cent.

The Problem of Timbering Anthracite Mines

Chief James E. Roderick of the Pennsylvania Department of Mines calls attention in his latest annual report to the gigantic and increasing costs of the anthracite mine operators, laying especial stress upon that of mine timbering.

"Of the many problems that confront the mine management," he writes, "the most serious is the timbering of the mines. With every passing year this problem becomes greater and more difficult to solve. Not many years ago, the initial cost of opening an anthracite colliery was deemed a serious obstacle to the undertaking; the great cost of keeping mines free from water was another annoying and expensive feature, but the timber problem now overshadows all others.

"This is a phase of the mining business which the general public knows little about, and yet the timbered gangways and drifts cover a vast extent. In the anthracite region the Philadelphia & Reading Coal & Iron Company has more than 800 miles of gangways and there is a total of 2000 miles of these underground ways in the Schuylkill region alone."

Yellow Pine Most Generally Used

Chief Roderick tells of the efforts of the operators to prolong the life of the timber by methods of preservation, and adds:

"Most of the timber now used in the anthracite mines is yellow pine from the South, and one of the largest anthracite companies, owing to the great demand and impossibility of getting timber in the North, has been sending its own cars South to expedite shipments."

When one reflects that a billion tons of water, or thirteen and a half times as many tons as the coal produced during the year, must be pumped out of the anthracite mines every year, and that the timbering is an even greater expense than this, the cost of placing this vast forest below ground seems staggering. According to a recent calculation, based on the material costs of a number of the larger companies, the anthracite operators spend $2,593,280 a year for mine timbers and "lagging" and nearly as much again for lumber. The use of steel timbers which are being adopted for permanent gangways on account of their longevity will add to this amount for the next few years, but it will mean a final saving in the replacement bills of the companies.

It is only by increased efficiency in every department and the introduction of mechanical labor-saving devices that the operators have been able to keep the price of anthracite down to its present level. The only changes in the wholesale price of anthracite since 1902 have been an advance of 25c. a ton in 1912 to offset the 10 per cent. increase in wages granted to labor that year and the increased cost of materials, and an advance of 10c. a ton this year to meet the expense of the new Pennsylvania State tax of 2½ per cent. of the value of the coal at the mines.

The Coal Supply of Italy

Italy is almost entirely dependent for its coal requirements upon foreign countries. It produces an inferior quality of lignite only, and that in a very limited quantity. In 1912, its production only reached 660,000 metric tons. Since 1900, the coal consumption of Italy has increased greatly, in consequence of the marked growth in population and the rapid gains in industrial progress. In 1913, the importation of coal, coke and briquets rose to more than 11,000,000 tons, of which France furnished 92,000 tons of coke, and Belgium 6000 tons of coal, 7000 of coke and 400 tons of briquets. By far the greatest part of its coal imports is drawn from England, which in 1913 reached 9,800,000 tons of coal, 71,000 tons of coke and 253,000 tons of briquets.

Although the United States has been finding a market in Italy for coal for the past 25 years, the deliveries have not been important, comparatively speaking; in 1913, they amounted to 281,000 tons. Germany furnished, in 1913, 892,000 tons of coal, 183,000 tons of coke and 133,000 tons of briquets.

As Austria cannot meet its own coal requirements, there is practically no exportation to Italy.

Note—Extract from a paper in Gluckauf, Aug. 22, 1914, by Dr. Ernst Jungst, Essen, Germany. Translated by Henry B. Binsse.

The Verner Theory of the Counter-Current and Where It Leads

By a Mining Engineer

SYNOPSIS—The writer contends that the article by Samuel Dean appearing in the issue of Aug. 22 fails to prove the correctness of the Verner theory of the counter-current, which theory, the writer believes, contradicts the laws of nature. Moreover, he suspects that the theory has done much harm by inducing shotfirers to reduce ventilation before igniting their shots with results which statistics appear to show are disastrous.

The discussion in Coal Age about John Verner's theory of a counter-current in coal-dust explosions appears to have had a revival following the article by Samuel Dean, which appeared in the issue of Aug. 22. The synopsis heading this article states: "The British Experimental Station accepts many of John Verner's conclusions as published in these columns."

As suggested by James Ashworth in the Sept. 19 issue, it would be interesting to know which of Mr. Verner's conclusions has been accepted. A student of explosion data does not find either in Mr. Dean's article or in the five reports issued by the British Commission, any avowed support of the theory.

Proving the Inrush Theory

The information given under the subheading in Mr. Dean's article, "Proving the Inrush Theory," while evidently accepted by Mr. Dean and by Mr. Verner, judging by his letter in the Sept. 26 issue, as proving their case, does not appear at all convincing. The pressure curve given is meaningless as it does not show the atmospheric line, and give the relative pressures and time intervals; also, to interpret the results, the distance between the pressure manometer and the shot must also be known. The observations of the swinging board placed at the mouth of the gallery, and of the dust and flame are also indefinite without records of the time intervals starting from the instant when the shot was fired. The chief difficulty apparent in all the discussions by Verner and Dean, is that they do not separate the effects of the igniting shot and of the explosion proper.

Vibratory Waves Are Universally Produced by Blasts

A study of the data and pressure curves obtained by any of the experimental stations shows conclusively that the air waves, started by a shot, travel at the rate of sound waves, 1100 to 1150 ft. per sec., the exact speed depending on the size and character of the gallery. These air waves are entirely independent of those due to the explosion, and are exactly the same in a test in which there is no coal-dust loading as when a violent explosion ensues.

Any violent vibration would set up waves similar to those indicated in Mr. Dean's incomplete sketched curves. But they will be different from those produced by a blast from an explosive because the impulse set up by the latter is due to the rapid evolution and expansion of heated gases, displacing a portion of the air previously in the neighborhood of the shot, the displacement of the air in the gallery being increased in the case of a shot fired near the inner end of a closed gallery by the inertia of the column of air set in violent motion.

The gases cool rapidly and no one with any knowledge of physical laws would deny that there would be an inward rush of air to fill the void, or partial vacuum. This would necessarily be a vibratory movement while atmospheric equilibrium was being reëstablished. One may, with a paddle, give a violent impulse to water in one end of a water trough, and there will be a return wave of almost the same size, followed by waves to and fro, until friction on the sides has absorbed the energy originally imparted.

The Use of Springs Makes the Indications Doubtful

When the blownout shot is a large one, the inrush following will be correspondingly large. It may easily carry in dust if present, also produce many effects like those noted by Mr. Dean; although in considering the importance of different movements of the board it may be pointed out that the use of springs to suspend and hold the board in the middle, does not commend itself as being good for scientific observation, since the springs when stretched, through the movement of the board in one direction would tend to pull it back with equal violence in the other direction, followed by other swings to and fro retarded only by the friction of the air and rod, thus making it impossible to draw any conclusions as to the movements after the first beyond the fact that there were other violent movements of the air, which everyone would concede in advance.

Now *if the inrush of air immediately following a shot* accompanied by eddying and dust raising, whether followed by an explosion or not, or, if the vastly greater inrush following an explosion of coal dust, constitutes Mr. Verner's so called "theory," it would seem to be acceptable to most if not all students of explosion phenomena; but there appears to be another feature in this theory, if his explanation is understood, namely, that there is an "inrush of air along the bottom" in the face of an advancing explosion of coal dust.

The Theory Violates Natural Law

This is the feature which appears incomprehensible, as it seems to be so completely in violation of the fundamental laws of physics. How can there be coexistent a great pressure of expanding gases and in the same area of combustion, a depression or void? According to manometric records in the galleries of England, France and the United States, the pressures due to an explosion may rise to over 100 lb. per sq.in., registered at the side of the passageway. When these pressures are high and the pressure or explosion zone is advancing at the rate of 1500 to over 2000 ft. per sec., how is it conceivable that anywhere in that zone, either at the floor or anywhere else, there can be an area of depression, or pressure below atmospheric which would cause a cool current of air to approach the high-pressure area and, as it were, dive under it?

Alleged Proofs Fail to Convince

Verner and Dean apparently accept two phenomena as "proofs" of their theory. These are the movements of débris toward the origin of an explosion, of which there can be no doubt and the reported statements of men that they felt incoming currents of cold air. As to the validity of these latter assertions there may be some doubt, for the men were without question in much mental agitation at the time.

They accept these as proofs without taking into account the *time* when the movements of débris or air took place or the relation of such movements to the path of the explosion.

All will concede that an inrush of air follows a shot, and continues in point of time until atmospheric pressure has been reached. If coal dust is present and ignites, a pressure is rapidly built up by the hot gases of combustion, which force their way in every direction where the pressure is lower. Also there is a great inrush following any explosion, and doubtless there is a partial vacuum, or depression of over half an atmosphere, say 7 or 8 lb. per sq.in., following an extensive explosion (records of five pounds have been reported), which unquestionably brings back over the path traversed by the explosion, many movable articles, often of considerable weight. The visible effects of this inrush or return current seem to be improperly attributed to the mysterious "counter-current."

The movement of air in the vicinity of a mine fire has been cited as evidence of similar conditions in the vicinity of an explosion. It has been said that the ingoing current of cool air along the floor, passing under the hot gases and smoke from the fire, resembles in its action Verner's counter-current. The conditions are not parallel; first, a fire compared to an explosion is stationary, and second, there is no pressure caused by an open fire, but only a small depression below atmospheric pressure. This is created by the hot gases, which, being lighter than air, rise and cause the heavier cool air to flow in below.

Blownout Shots Only One of the Causes of Explosions

If we are to get at the "bottom" of the Verner theory, it does not seem wise to confuse the issue by paying too much attention to the movements surrounding a blownout shot; according to authentic reports, there are many other ways in which coal-dust explosions have been caused, such as overcharged, but effective shots of long flame-producing explosives, pockets of firedamp and ignition of coal dust by electric arcs from grounding of trolley or power wires. No one can sanely question that at the point or origin of a coal-dust explosion, there must be violent agitation and eddy action of the air to bring the dust into action, for in very few instances is there sufficient coal dust in the air beforehand.

It is to be noticed that Parfitt and Verner in the Sept. 26 issue of Coal Age, endeavor to combat that part of Mr. Ashworth's letter in the Sept. 5 number, in which he says "that no such reverse current could be produced until the force exerted by the powder or other explosive had expended its energy. It would seem that at the point *C* (points on either side of the mouth of the borehole shown) in the figure, the air would be in a state of compression, instead of a depression or vacuous condition" existing, as he (Mr. Parfitt) stated, assuming "that the shot was fired in the face of a heading."

Is There a Vacuum during an Explosion?

Mr. Ashworth's opinion seems founded on laws of physics, and is supported by the data obtained at the various experimental galleries. For instance, in the Altofts experiments to which reference has so often been made, the cannon was placed in a gallery which was, to all intents and purposes, open at both ends. The gases and flames in many of the tests not only went in the direction the cannon was pointed, but also back past the cannon due to the pressure created by the shot and the explosion (see experiment 116 and others).

There was further direct proof of the pressure surrounding a shot reported in Bulletin 56 of the U. S. Bureau of Mines, entitled "First Series of Coal-Dust Explosion Tests" at the experimental mine, given on p. 39, where in the endeavor to start an explosion from the outside of the mine through a gallery, the cannon was placed against a plank stopping and a hole cut in the same opposite the borehole. The report states "The plank stopping was burst *outward* by the effect of the shot," although it failed to cause an explosion.

An issue might be raised with Mr. Ashworth about the last part of his statement "that when a shot blows out, the heated gases and particles of solid matter are projected into the main roadway, where the blast stirs up the dust. *At this initial moment, the immediate atmosphere in the vicinity is quickly rendered devoid of oxygen, which makes an explosion of the dust and gases at that point impossible.*" Mr. Parfitt considers this as supporting Mr. Verner's theory.

Explosives as Manufactured Support Their Own Combustion

The question is, why should the atmosphere be devoid of oxygen unless the combustion of firedamp or coal dust has already begun. In other words, Mr. Ashworth and Mr. Parfitt evidently overlook the fact that manufactured explosives of all kinds have their self-contained supply of oxygen, which is nearly enough for complete oxidation, though some further burning may continue in the atmosphere.

The gases from the blast would contain a large percentage of inert gas, but as compared with the amount of air present in an entry of ordinary size, the quantity of gas would be small (and it could easily be figured). Further, the heated condition of the gases and the formation of gas of a most highly inflammable character like CO would offset, in effect, any slight decrease in total oxygen available for the combustion of coal dust in the vicinity.

To What Does the Argument Lead?

In conclusion: If for the moment we assume there is a "counter-current," where does it lead us? What does it mean? Does it bring us any nearer to the prevention of explosions? It has been hinted that it suggested the cutting off of the supply of air in the mine, and this method has been practiced by shutting down the fan at shotfiring time in some Western states, including Mr. Verner's state, Iowa, and notably in Kansas and Oklahoma, which states are reported to have more explosions from shotfiring than occur in any two other coal-mining states in the country of many times their output. One

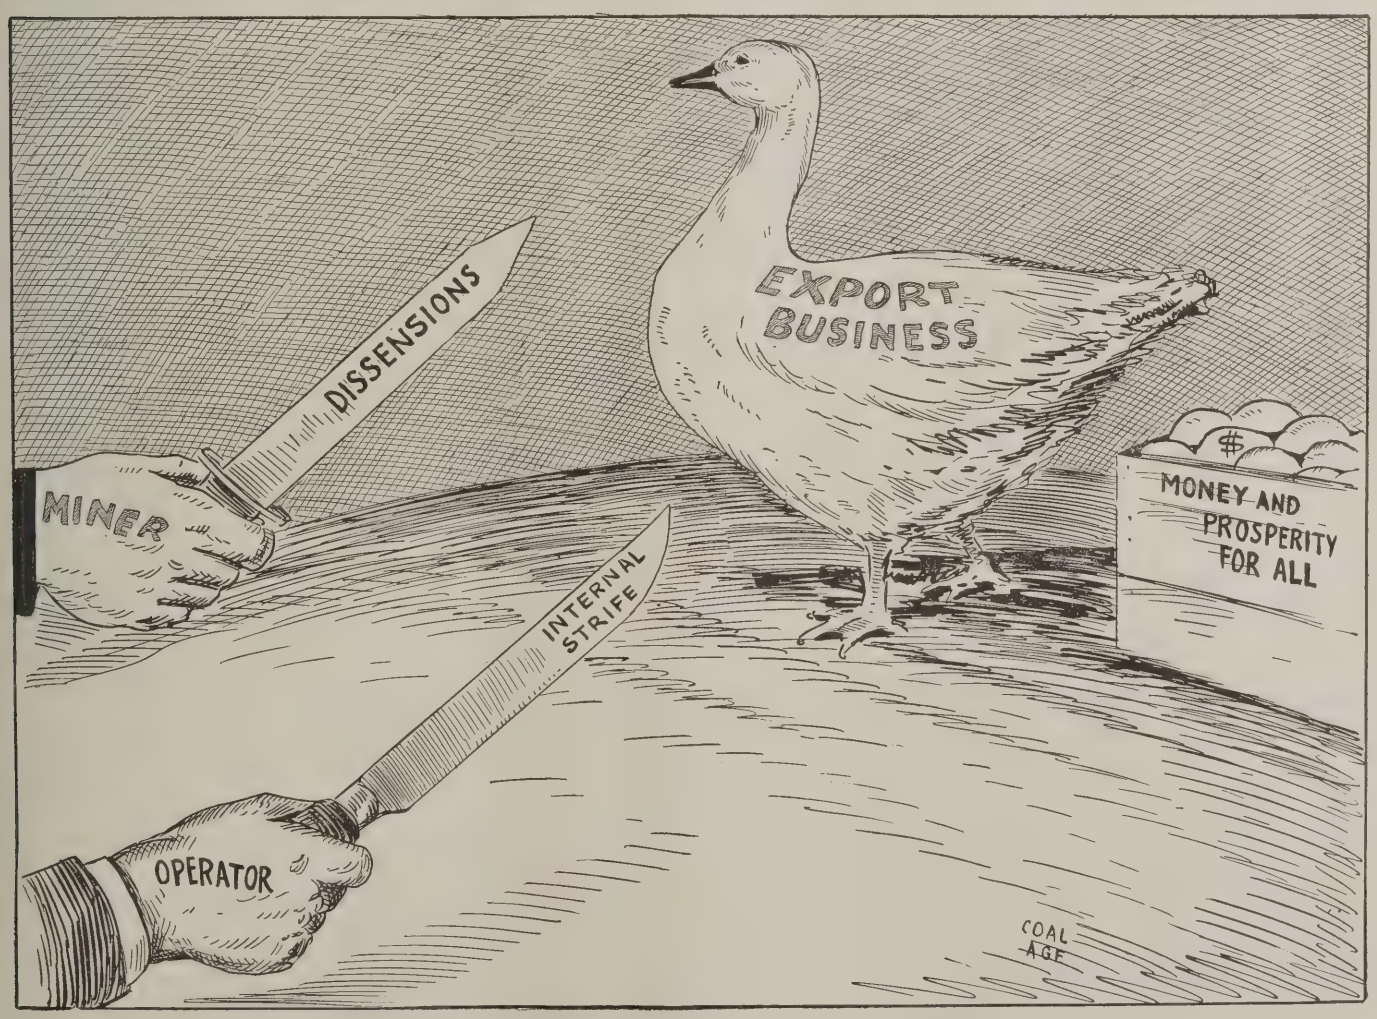
mine is said to have had three in a single year, and another operation two in one month.

Is that what the theory leads to? If it does not, it should be made clear that it only deals with the internal mechanism of an explosion, is of theoretical interest only, and has no relation to the prevention of such unfortunate occurrences as otherwise the general mining public which has neither the time nor the means of studying the matter, is liable to be seriously misled.

Opportunity for Export of Mineral Fuels

In its reserves of mineral fuels, the United States holds an impregnable position as a world power in industry and commerce. Our production of coal overtops that of any other nation and, in fact, nearly equals the combined output of Great Britain and Germany, the nations that rank second and third.

Inasmuch as the United States leads the world not only in coal production, but also in low cost of coal mining, and apparently possesses the greatest reserves, it follows, as was pointed out by Campbell and Parker in 1908, that foreign countries will obviously look more and more to the United States for their supplies of coal. The lower cost of production in the United States, which is due largely to the favorable location of the coal beds and the extensive use of mining machines, is offset in Great Britain by the proximity of the coal mines to the seaboard.



The wages paid in the United States are higher than in any country of Europe. This country's preëminence in the production of petroleum is even more conspicuous, so that the opportunity for exporting mineral fuels presents no immediate problems for the domestic producer.

Mining Active in Virginia

The mineral production of Virginia increased in value from $14,995,842 in 1912, to $17,178,580 in 1913, according to the U. S. Geological Survey.

Virginia ranks relatively high among the states in the variety of mineral substances produced on a commercial scale, but somewhat low on the list in the value of the production. Virginia is the leading state in the production of iron pyrite used in the manufacture of sulphuric acid, and in the production of manganese ore, and is the only state in which rutile is produced. It also ranks first in the production of soapstone, most of which is manufactured before being marketed into heat and chemical-resisting articles; such as hearthstones, mantles, griddles, sinks, etc.

The product of chief value, however, in the state is coal, which represents something more than 50 per cent. of the total value of the mineral production. The production in 1913 amounted to 8,828,068 tons, valued at $8,952,653, against 7,846,638 tons, valued at $7,518,576 in 1912, an increase of nearly a million tons.

Don't Kill the Goose That Lays the Golden Eggs

Electrification of the New River Co.'s Mines

By Edward L. Sayers*

SYNOPSIS—Shortly after organization, the New River Co. equipped all of its mines with direct-current apparatus. Today, it is rejecting this equipment and placing in its stead alternating-current machinery of modern design.

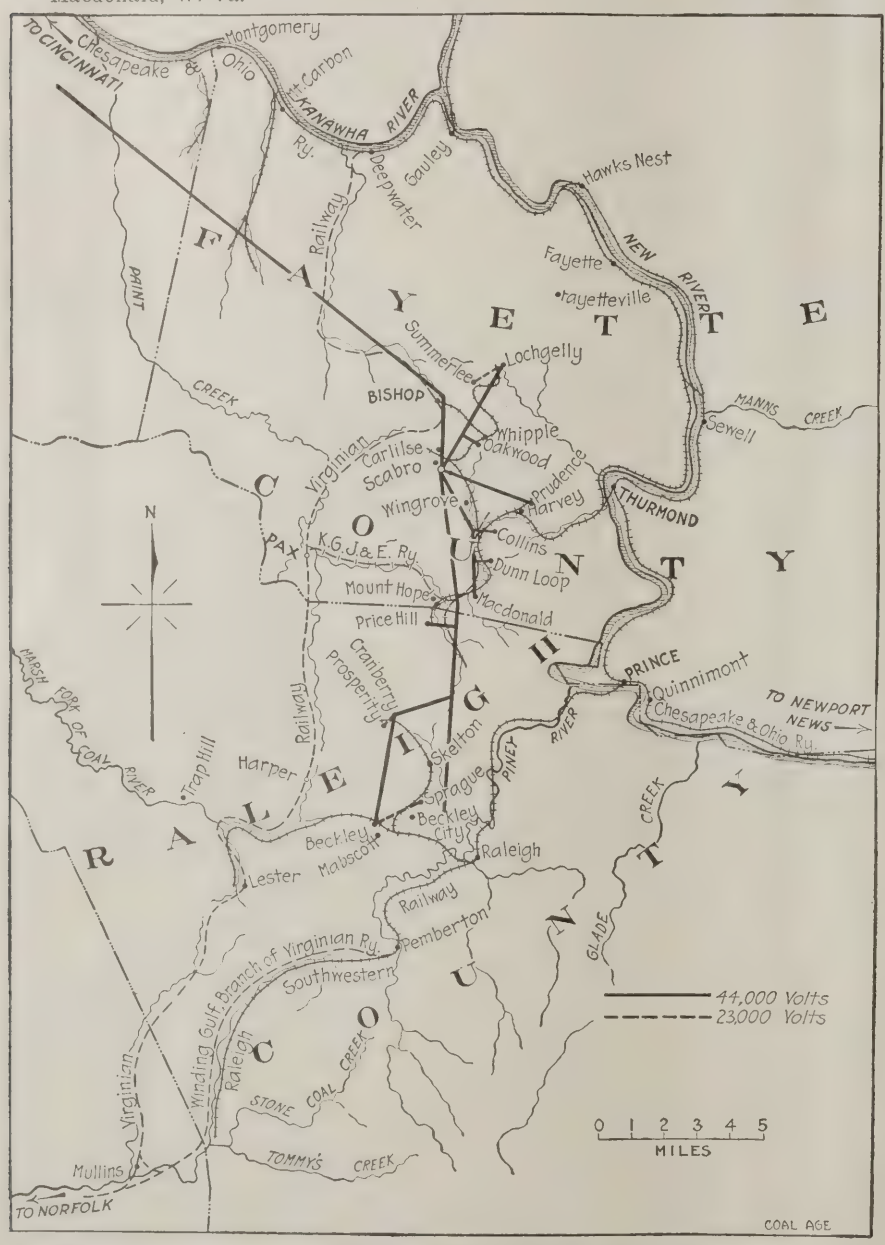
The New River Co. was organized in 1906 to carry on a general coal-mining business in West Virginia. Shortly after organization, it purchased a number of other concerns, some operating and some still in the development stage, and later it opened up new mines.

At present it owns 14 mines in the Dunloup Creek district and six in the Cranberry or Beckley district. The first of these operations was opened up in 1893, at Macdonald, and the last was put into working condition at Price Hill, in 1908.

At the time the New River Co. acquired these mines, only one or two were equipped with electric generating units, while now there are 25 direct-current generating units at the mines, ranging between 60 kw. and 250 kw. in capacity. In line with the progressive policy of the management of this company, a contract has been executed with the Virginian Power Co. for a supply of alternating current, and an entirely new equipment is being installed.

The Virginian Power Co. recently ran transmission lines into this region from its central power station on the Kanawha River, near the mouth of Cabin Creek. The line through the Dunloup and Cranberry districts is shown on the accompanying map, as is also the plan of distribution to the several mines.

At Scarbro there is a general meter station for measuring the energy used in the Dunloup Creek District, and near Cranberry there will be a similar installation for measuring the power consumed in that district.



The alternating current supplied on the main transmission line is 44,000 volt, 60 cycle, three phase. Distribution lines of 44,000-volt potential radiate from the Scarbro metering station to Lochgelly, a distance of four miles; to Prudence, three miles, and to Macdonald, five miles, while a 2300-volt line runs to Carlisle and Oakwood, about one mile away. The line to Lochgelly provides for Summerlee through a transformer station at the former point, and Whipple is taken care of by a similar station on the branch line opposite the mine.

The line to Prudence supplies power to Harvey, which in reality is operated as one mine with the former operation. The line to Macdonald picks up the load at Collins and Dunn Loop, at which points there are separate transformer stations stepping the potential down from 44,000 to 2300 volts for use in the motor-generator sets and the large pumps, and from this voltage to the lower pressures used for lighting, ventilating and pumping.

The main transmission line between Scarbro and Cranberry will be tapped near Price Hill, and a transformer station there installed to lower the voltage for use at that mine.

From the metering station near Cranberry, a 44,000-volt line will be

*Macdonald, W. Va.

Map Showing Location of the New River Co.'s Mines in West Virginia

run to Cranberry and to Beckley, while 2300-volt lines will be built from Cranberry to Prosperity and from Beckley to Sprague. Mabscott is supplied with direct current from Beckley.

Scarbro-Wingrove, Summerlee, Whipple, Lochgelly, Cranberry-Prosperity and Carlisle-Oakwood are shaft mines, the average depth of which is about 475 ft. The standard hoists selected for these mines have two conical drums varying from 6 to 9 ft. in diameter, driven by 400-hp., 2300-volt induction motors, at a speed of 600 r.p.m. In the case of the Cranberry mine, the shaft of which is 467 ft. deep, a maximum rope speed of 1910 ft. and an average of 1655 ft. per min. are guaranteed. The time of acceleration is 6 sec., of retardation 5 sec. and of caging 7½ sec., and the overall mechanical efficiency is 80 per cent.

Hoists will also be installed at Beckley and Sprague, which are slope mines. The old d.c. voltages of 250 and 550 are being retained in the mines for electric haulage, and motor-generator sets using 2300-volt alternating current and delivering 300 or 600-volt direct current are being installed at the various plants.

Pumps have been standardized into three types, as follows: 3½x4-in. horizontal triplex pumps mounted on trucks with 5-hp. d.c. motors for 1000 r.p.m., and either 250 or 500 volts, depending on the standard of the mine; 5x12-in. horizontal duplex pumps driven by motors ranging between 15 and 35 hp., and 10x18-in. horizontal duplex pumps driven by 90- to 125-hp. motors. On these larger machines, 2300-volt alternating current is employed.

The standard ventilator now being installed is a 9x4-ft. double-inlet exhausting reversible fan, driven by a 50- or 75-hp. motor taking 2300-volt alternating current and operating at 580 r.p.m.

All of this new equipment embodies the latest improvements in mine machinery, and, in fact, it has always been the policy of the New River Co. to keep abreast of progress in methods of mining coal. At the time it acquired the mines in this district, it discarded practically all the machinery then in use, at once installing new and modern equipment. Times have changed since then, however, and now practically all of the equipment then representing the best practice in coal production must be disposed of, giving way to the still more modern and efficient alternating-current machinery.

Some Notes on the Panama Canal Routes and Coal Markets

SYNOPSIS—While the canal route will materially shorten the distance from the Orient, it does not bring the Atlantic seaboard coaling ports closer to any important industrial or manufacturing center. Southern ports have the greatest advantage. Competition with oil is an important consideration.

The Panama Canal will not bring the Eastern seaboard of the United States distinctly nearer to any one of the manufacturing countries of the world. Accordingly, one is not to expect that the opening of the great waterway will seriously affect our exports of coal. We are annually exporting to foreign countries in the neighborhood of 23,000,000 tons of coal and coke, having a value of about $69,000,000; but the great bulk of this goes to Canada. The canal may change the situation somewhat, but nothing radical need be expected at once.

China and Japan will be brought considerably closer by sea to New York and New Orleans, but these two countries are themselves producing about 35,000,000 tons of coal. That their importations from other regions are comparatively small is illustrated by the fact that from Great Britain they get only about 45,000 or 50,000 tons annually. Eastern Australia and New Zealand will be very much nearer to our Atlantic Coast by sea, but this district is mining about 14,000,000 tons. If these two districts of the Western Pacific—one in the north, the other in the south—are importing coal in any considerable amount, they are not getting it from the United States nor from Great Britain.

Shortening of Routes

The western part of South America will be brought into a much closer maritime relationship with eastern United States. As this entire district produces but a moderate amount of coal itself,* and as it has already become a buyer, we may expect that the canal will have an immediate effect upon American coal exports to this quarter of the world.

The particular countries involved are Colombia, Ecuador, Peru, Bolivia and Chile. Two of the principal ports are Callao, Peru, and Valparaiso, Chile. The following tabulation exhibits the change brought about by the canal in respect to all-sea routes from ports in the eastern section of the United States.

Shortening of Sea Routes Between Eastern United States and Western South America (in Nautical Miles)

Port	Through Straits of Magellan	Through Panama Canal	Decrease
Distances from New York—			
Callao	9603	3392	6211
Valparaiso	8460	4637	3823
Distances from Hampton Roads—			
Callao	9505	3136	6369
Valparaiso	8273	4437	3836
Distances from Philadelphia—			
Callao	9603	3302	6301
Valparaiso	8371	4603	3768
Distances from Baltimore—			
Callao	9629	3260	6369
Valparaiso	8397	4561	3836
Distances from Charleston—			
Callao	9521	2924	6697
Valparaiso	8289	4225	4064
Distances from New Orleans—			
Callao	9986	2744	7242
Valparaiso	8754	4045	4709

Callao is not now one of the leading South American ports, in so far as coal is concerned; yet its position makes it representative of the northern part of the coast in respect to distances.

It should also be remembered that the Panama Railroad and the National Railroad of Tehuantepec even now offer as short a route as the canal will. The one railroad has approximately the same location as the canal,

*Chile is the chief producer of coal in South America. In 1913, it produced some 1,400,000 tons. This was far short of the requirements, as she imported some 1,200,000 tons, nearly all of which came from Great Britain and Australia.

and the other crosses Mexico at the most southern point of the Gulf of Mexico. These routes can scarcely come into competition with the canal in respect to shipments made in bulk despite the partial offset of the charges through the locks. The change from ship to railway and from railway to ship involves heavy expenses. These are not due simply to the mere cost of unloading and loading, but to the difficulty of handling the ships economically. A ship that discharges her cargo to the Panama R.R. at its Atlantic terminus must be forthwith supplied with a return cargo. This is a difficult condition to meet and even then the freight rates through the canal would probably be considerably less on bulk shipments.

If, then, there is any coal business in western South America, it will in all probability go through the canal. Bolivia and Columbia do not participate in this business and Peru makes only a small showing. But the latter country has been buying coal. In the fiscal year 1907-1908, she purchased 30,925 tons of bituminous coal from us, the valuation being $90,251. In the fiscal year 1909-1910, she dropped to 84 tons, but the following year there was a partial recovery, the total being 19,446 tons.

Shipments from the United States to Peru and Chile

Shipments of coal from British ports are indicative of the existence of some business. Apparently, these shipments have been pretty well confined to Peru and Chile. Australia also shipped considerable to Chile.

SHIPMENTS FROM THE UNITED STATES TO PERU AND CHILE

Country	1908	1909	1910	1911	1912	1913
Peru	30,925	11,350	84	19,446	39	9,209
Chile	59,963	28,282	39,183	26,688	29,751	112,067

It is evident from this table that Peru and Chile are both in the market for coal. We may assume that the United Kingdom and Australia will be our chief competitors in the period following the opening of the canal. The canal will put our Atlantic seaboard in a much better position than the best situated of British ports. The route from Cardiff to Valparaiso via Panama Canal is but little shorter than by way of the Strait of Magellan. So that coal shipments might go either way in unbroken cargoes. The enormous advantage possessed by our Atlantic seaboard is one which should be taken under consideration. With such an advantage, it would seem that we ought to do a considerable business from the ports of Philadelphia, Baltimore, Hampton Roads, Charleston and New Orleans.

As between American ports, a consideration of the lengths of the sea routes points to the southern ports as the ones which should handle and develop this South American business; Philadelphia might also be included. Norfolk and Charleston are the most southern of all the coal ports within reach of the Atlantic Ocean. Baltimore, while somewhat more distant by sea, is quite near to a great bituminous coal field. New York is not a natural port for this business, being more remote both by sea and rail. Eastern United States ports from Philadelphia south are the chief ones concerned.

Coal in Competition with Oil

The coal resources of western South America are apparently rather limited. Chile is producing about 1,300,000 tons annually. The others are mining a negligible amount. These countries are increasing their manufacturing industries. The business now being done with them by the United Kingdom, Australia and the United States is relatively small. But the Panama Canal will put us in a more favorable position to get a large share of the business, even if it be granted that conditions have heretofore been against us.

In recent years, oil has entered the field as a competitor of coal. This substitution is being energetically pushed especially in respect to railways and ships. In California and Russia, the railways are making extensive use of oil. Russia, for example, uses annually on her railroads 650,000 to 700,000 long tons. It would also seem that the naval authorities in the United States were abandoning the use of coal in respect to new ships. Thus, the United States has now, either built or under construction, 4 battleships, 41 destroyers, 30 submarines, 1 monitor, 3 tank ships, etc., all designed for burning oil and nothing else. The U. S. Navy uses oil at the rate of about 30,000,000 gal. per year. Whether the British Navy will definitely commit itself to oil, it is perhaps too early yet to say. The indications are that it will do so in large part or entirely when the authorities are convinced that an adequate supply will at all times be available.

From a consideration of such facts as these, the conclusion would seem warranted that the next few years will witness important displacements of coal by oil. It may be expected that this movement will affect to some degree the shipment of coal from the United States to the west coast of South America. Whatever oil this district consumes, as its industrial development goes on, will come presumably from four oil fields. These are California, Texas, Mexico and Peru. If the British Navy goes over to oil, we may expect the shipments of best quality Welsh coal to fall off and disappear. But this will hardly affect the exportation of coal from the United States.

However, the supply of mineral oil seems to be limited, so that we may expect the price to advance constantly with the widening of the field of application. The coal supply of the world, and of the United States in particular, appears to be well-nigh inexhaustible. Oil consumption may temporarily retard exportations from attaining their full proportions and also result in a shading of coal prices. But unless some great unexpected sources of supply are discovered, coal will undoubtedly continue well in the lead.

What's the Use?

By C. W. Crawford*

The inducement to builders of hoisting engines to fall over each other in a scramble to furnish a higher class of such machines is meager. Heretofore any old rattletrap that would wind a rope was good enough to hoist coal. Coal has been so plentiful and so easily secured that operators did not discover any dignity in the trade of making engines. Only the sale of coal and the manipulation of coal lands commanded their enthusiasm. So easy it has been to "make good" in coal mining that many of the leading operators have become millionaires (?) and the rest are following in their wake with fair prospects.

The output of coal per each mine is increasing as rapidly as the engines can be pushed to further duty, and

*President, Crawford & McCrimmon Co., Brazil, Ind.

the engineers can be induced to handle their machines more rapidly, regardless of increased risk. Engines that may be rated as small ones are made to do the duty of larger machines by rapid rotative speed and by using small winding drums.

Engine builders are not encouraged to design better machinery, but the same kind their fathers built— and it must be cheap. No innovation nor even a streak of brains is cared for. Greasy mechanics don't know what is wanted in hoisting coal anyway. Engines are made (for this purpose) just as they were 50 years ago with whatever added display the builder can afford for his own gratification, or for a talking point against his competitor. However, upon one point all are agreed—the engines must be more easily handled than formerly. The engineer demands this, and the operator encourages it for the greater output; and the builder in securing greater ease in handling scores a good record, but the operator gets the money.

It usually happens that the operator is the purchaser of new machinery outfits for coal mines, and he assumes that the existing styles are good enough, and but little inquiry is made about better methods. Local preference occasionally prevails but usually only the price is considered, and then ill considered. The battle of prices is generally centered on the hoisting engine regardless of the example of the shrewd dealers in less important detail equipment. And it frequently happens the buyer pays more for a fan to ventilate his mine than he does for the hoisting engine. Or he pays a liberal price for a separator in the installation of the pipe line, that might be made by his engineer, out of pipe fittings, that would be infinitely better and at almost no expense.

Without decrying the quality of any of these goods, the care in the choice of the hoisting engine would seem to be the more important, inasmuch as it is the money maker, while the others are only accessories. But it is unfair to disparage the existing engines, for they are usually well made—for the price—but incomplete. No security against a runaway is provided.

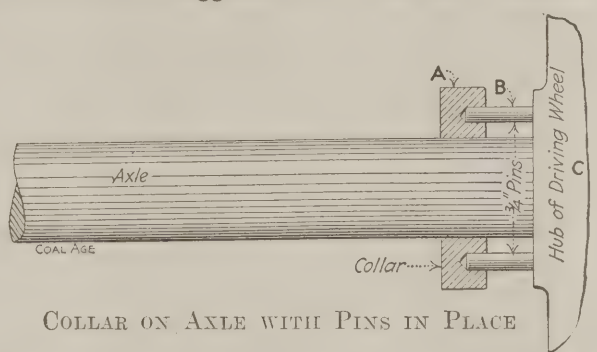
No security against overwinding that will stop a runaway cage having a million foot-pounds of energy stored in it, acting in the space of a few feet and in a fraction of a second of time is vouched safe. It is no censure to the engineer to say he might become paralyzed, or he might drop dead during a hoist—similar accidents have happened.

It is never mentioned in the books or in the advertisements that the momentum of a cage and load at rapid runaway speed is extraordinary, and no estimate of the strength of any device that will stop a cage and load instantly is ever offered nor of the breaking stress or of the energy stored in a 20-ton winding drum revolving at high speed.

That such stress is extraordinary is attested by the number of broken ropes and the number of men killed by falling cages. The excuse of the operators that they all use safety catches cuts no cheese, for they all know such devices are not wholly and always reliable. But they are only culpable in that they do not demand something that is reliable. If such a device were wanted and asked for, it would be forthcoming. It need not be very expensive—the cost of one smashup would pay for it, and then some.

But, however, this is a deeper problem than most men know or think. In a bad runaway the momentum of the heavy winding drum added to the pull of the engines usually parts the rope. The factor of safety doesn't count, and the investigating committee and the coroner finish the job. Dead men have no rights, to speak of, and relatives and insurance companies get the worst of it.

A safety device to be absolutely safe and reliable would be a whole lot different from the "as if" devices generally used and would necessarily add somewhat to the cost.



And there's the rub. That is the sticker that heads off the incentive to improve. A few radical improvements are needed, such as a system of expansion and a steam separator. But why contend against the choice of the operators, or the rebuff of the boiler makers? What's the use?

A Scheme to Prevent Collars from Shifting on Locomotive Axles

By Frank Walker*

Repair men who have locomotives of the outside-frame type probably know how nice it is to have the collars slip on the axles, causing the gears to rub on the gear pans, thereby destroying them.

I have tried a good many remedies for this condition but the one here suggested is the best one I have found,

Collar on Axle with Pins in Place

and after it is applied, I have no further trouble from that source.

The accompanying sketch is almost self-explanatory. Remove the collar *A* from the locomotive axle, and drill two holes in the face next the driving wheel and insert two pins of such length as to hold the collar the proper distance from the wheel, which distance should be ascertained with accuracy before the collar is removed.

Production of Madison County Illinois

Thomas Cunningham, of Edwardsville, mine inspector of Madison County, Illinois, has filed his annual report, showing conditions of the Madison County mines for the year ending June 30, 1914.

During the year 26 mines were in operation, employing 4545 men, who dug 3,689,544 tons of coal. The report shows that 8 men were killed, or one for each 461,192 tons of coal mined. There were 85 nonfatal accidents. In the preceding year there were 12 deaths and 116 nonfatal accidents. Four of the men killed during the last year were killed by electricity.

The miners used 46,372 kegs of powder during the year, or a total of 1,159,200 pounds of powder, an average of one pound to each three tons of coal.

*Vandergrift, Penn.

The Coal Field of Sebastian County, Arkansas

By Edward F. Hackett*

SYNOPSIS—The coal is found in what are known as the Backbone Ridges, and is of a quality low in volatile matter and in ash. Although the measures have a decided dip, the mining conditions are generally favorable.

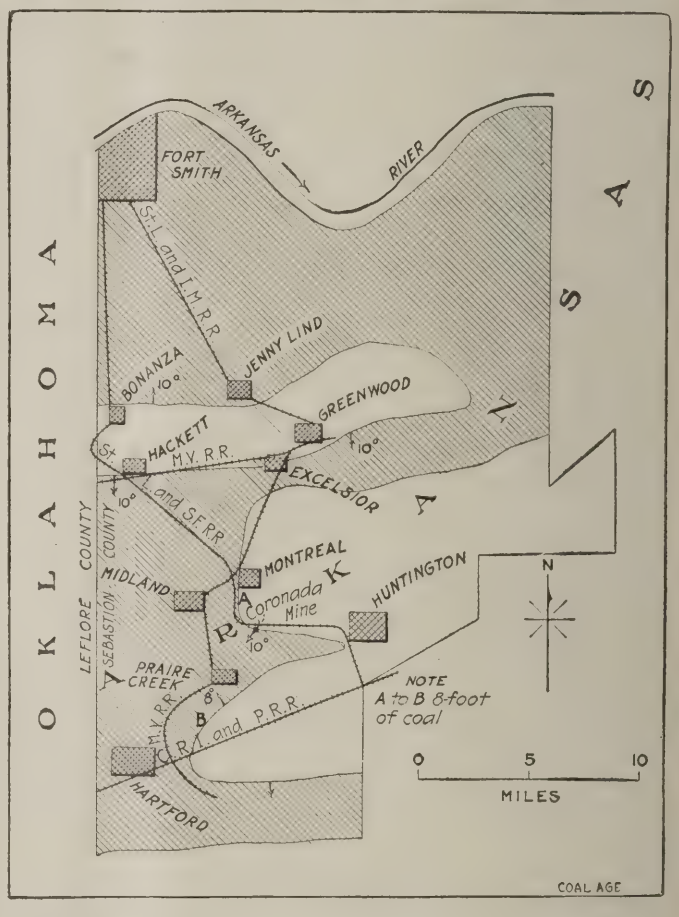
In the Backbone Ridges of Sebastian County, Ark., occurs the outcrop of the coal measures from which is produced the famous Arkansas smokeless coal. These ridges beginning in Le Flore County, in eastern Oklahoma, enter Sebastian County between the towns of Bonanza and Hackett, extending thence eastwardly for several miles, where they split, one part bearing northeast and the other east and south.

At Bonanza the coal dips to the north at an angle of about 10 deg., outcropping along the foothills of the ridge. The outcrop runs practically due east to Jennie Lind, where it turns to the northeast and rounds the point of the ridge, coming back on the south side. At Greenwood the coal is worked by slopes. It here dips to the south at an angle of about 10 deg., the thickness of the seam varying from 4 to 5 ft. The field is here comparatively narrow and the coal bed comes to surface on the north side of the east prong of the Backbone Ridge.

At Excelsior the field narrows to about 1½ miles. West of this point there have been located several small slopes which show the coal to be from 3 to 4 ft. in thickness, and to maintain a uniform pitch of from 8 to 10 deg. About two miles east of Hackett the coal decreases in thickness to 24 in. in some places.

Hackett is probably the oldest mining town in the county, coal having been first produced here in the year 1884 by the Kansas & Texas Co. This operation was, however, abandoned in the year 1890. West of the town is located the Branner Coal Co.'s slope. At this point the coal dips due south at 10 deg., and shows 4 ft. in thickness.

An analysis of the fuel obtained from this slope shows the following results: Volatile matter, 13.10 per cent.; fixed carbon, 80.01; ash, 6.89; B.t.u. content approximately 13,000.



About two miles west of the Branner slope the outcrop again enters the State of Oklahoma, and is then known as the Panama Segregation by the U. S. Geological Survey.

On the south outcrop, which turns south from Excelsior with the ridge, no developments have been made until Montreal has been reached. This latter place was for several years one of the mining centers of the state, but has been abandoned for some time. At this point, the coal averages three feet in thickness and was worked by slopes and by stripping.

From Montreal to Coronado, located on the St. Louis & San Francisco R.R., the coal averages about 3½ ft. in thickness, but the outcrop has been pretty well worked out.

From Coronado mine on, or between approximately the points *A* and *B* on the accompanying map, the coal increases in thickness, but carries a dirt band 10 to 12 in. thick. The upper bench averages 3 to 3½ ft. in depth, and the bottom from 3½ to 4 ft., the two measures remaining in close proximity throughout the Coronado, Huntington and Prairie Creek districts to a point near Hartford. In the Prairie Creek district, however, the dirt band decreases to about 4 in. in thickness.

At Hartford, the bottom vein disappears and only the upper bench is worked. This dips practically due south and shows from 4 to 4½ ft. of clean coal. The country east of Hartford being rough and without transportation facilities, little development has been made in this section.

Map Showing Coal Areas of Sebastian County, Ark.

The mining conditions in Sebastian County as a whole are good, the roof being of excellent quality and requiring but few props in the 8-ft. coal.

Practically all of this coal bed is overlaid with a stratum of hard, tough sandstone. Firedamp is found in small quantities, but open lights are used exclusively throughout the fields, accidents from gas explosions being extremely rare.

The mines are worked upon the room-and-pillar system. The usual method of preparation throughout the field is by passing the run-of-mine coal over shaking screens. As a rule four sizes are made, the slack passing through a

*Spiro, Okla.

⅝-in. screen, the pea through a 1¼-in. screen and the nut through a 2½-in. screen.

The Arkansas state law calls for payment on the run-of-mine weight before the coal is passed over any screen. This, together with the soft nature of the coal found in Sebastian County, and the practice of shooting from the solid, causes the slack production in this field to be extremely high.

Arkansas as a state has no legal requirements for either mine inspectors, mine foremen or fireboss, or, as he is called here, "gas boss." In fact what laws have been put upon the statute books from time to time are widely scattered, and it would require an attorney-at-law some time to sift them all out. Consequently, with the exception of a few of the major statutes, the balance remain upon the books and are unknown to the general mining public. It is quite probable, however, that the present chief mine inspector, Mr. Thomas Shaw, of Midland, has done more for the safety of miners and mining interests throughout the state as a whole in the past 12 months than has ever been accomplished before.

Don'ts for Outside Foremen*

1. Don't forget that your position and responsibility demand strict sobriety, and do not hire or allow to remain in your employ any subordinate official addicted to the use of liquor.
2. Don't fail to see that the provisions of the mine law, so far as they apply to you, are obeyed and carried out.
3. Don't fail to see that all dangerous machinery and all dangerous places are properly protected as required by the mine law.
4. Don't wait until some other official calls your attention to dangerous conditions; detect them yourself and have them remedied.
5. Don't wait until the fire insurance inspectors come around and report to you dangerous conditions.
6. Don't fail to have a signal apparatus placed at important points in every breaker, washery or tipple, for promptly notifying the engineer to stop machinery in case of accident.
7. Don't fail to observe the law governing minimum age of oilers, breaker engineer and other employees.
8. Don't fail to keep all steam boilers in safe condition, properly equipped and examined.
9. Don't forget that thorough and efficient examinations and inspections before accidents bring better results than the same work after an accident.
10. Don't forget that we expect you to help us educate the employees to take care of themselves, and this can best be done by personal instruction and attention.
11. Don't get excited if anything goes wrong; keep your head.
12. Don't fail to correct or discipline anyone you find doing anything wrong or violating the rules.

*From Susquehanna Coal Co.'s Book of Instructions.

A Reinforced-Concrete Lining for Mine Shafts

What is believed to be an entirely new application of reinforced concrete was recently undertaken at the Glenmeller Collieries, at Haltwhistle, Northumberland. This consisted of lining two new shafts with concrete slabs reinforced with expanded metal.

These slabs, which were cast in molds on the site, were made 3 ft. 1 in. long, 1 ft. 6 in. wide, and 5 in. thick. They were reinforced near their concave surface with expanded steel of a cross-section of about ¼ sq.in. per foot of width. They were tongued and grooved to allow of their being fitted and keyed into each other, the joints being later filled with cement grout so that the slabs formed a monolithic cylinder when placed in position.

A hole was left in each slab about 1 in. in diameter to allow of its being slung and lowered into position after it had been allowed to season for a reasonable length of time. This hole also served as an inlet for cement grout to be injected into the filling behind the slabs after they had been fixed in place.

The two shafts in question were sunk through water-bearing strata which had been previously treated by the Francois method of cementation. During the process of fixing the reinforced lining in position, the space between the lining and the face of the strata was filled with ordinary concrete into which cement grout was injected after the reinforced lining had been secured in place. This rendered the shaft water-tight.

It is said that this new lining possesses certain advantages over the ordinary brick lining as it is more impervious to water and requires no outlay in upkeep expenses once the work is completed. The shafts lined as described above have been subjected to ordinary working conditions for some time past.

Coal Markets of Cuba

Practically 96 per cent. of the anthracite coal imported into Cuba during the fiscal year ending June 30, 1913, came from the United States. In other words, of the total amount imported into Cuba for that period, which was 228,238 tons, valued at $774,333, 220,965 tons, valued at $731,636, came from the United States.

The total amount of bituminous coal imported into Cuba for the above named period was 1,125,094 tons, valued at $3,630,750; of this amount, 1,118,347 tons, valued at $3,598,121, or about 99 per cent., came from the United States.

Some of the largest consumers of bituminous coal in Cuba are:

The Spanish-American Iron Co., Santiago de Cuba.
The Juragua Iron Co., Santiago de Cuba.
The Cuba Copper Co., Santiago de Cuba.
Cia. Electrica de Santiago, Santiago de Cuba.
The Santiago Ice Co., Santiago de Cuba.
The Santiago Brewing Co., Santiago de Cuba.
The Cuba Railroad Co., Camaguey, Cuba.
The Guantanamo & Western R.R., Guantanamo, Cuba.
Julian Cendoya, Santiago de Cuba.

American Institute of Mining Engineers—The next annual meeting of the Institute will be held in New York City beginning Feb. 16, 1915. Papers to be presented at this meeting should be in the hands of the Secretary of the Institute not later than Nov. 23, 1914, and as much before that date as possible. If a manuscript is received after Nov. 23, the editorial staff will lend its best efforts to having it prepared in time for the meeting, but cannot give assurance that it will be ready in time. Bradley Stoughton is secretary.

The United States Bureau of Mines, in coöperation with the United States Geological Survey, has undertaken additional and more comprehensive investigations pertaining to the problem of mine caves and surface support. The immediate work of the mining engineers and geologists will comprise detailed studies of the extensive open-cut and underground mining operations in southwestern New Mexico. The field investigations will be conducted with special reference to earth pressures and surface subsidence in relation to the geological formation and mining conditions, and the equipment and efficiency of the large mechanical installations in operation there.

To make your boiler settings tight, scrape them thoroughly and make a thin mix of fireclay or cement or both and let the brick absorb all the mixture they can. Then paint the brick over with an asphaltum-base paint of a kind which will not run at the temperatures which the bricks will attain.—Bromley in "Power."

Power Department

Power Generation at Collieries*

SYNOPSIS—Although the utilization of exhaust steam in low-pressure turbines may appear economical, the internal-combustion engine is more efficient than a steam plant. It is believed that the vertical, double-acting, two-cylinder, two-cycle engine will be the favorite of the future for colliery work.

Until recent years economy in fuel at collieries does not appear to have been considered of any great importance. Even at the present day it does not receive at many pits the consideration that it deserves, and wasteful engines for pumping, ventilating, haulage, etc., are used, the consequence being that millions of heat-units are thrown away into the atmosphere every hour in the form of exhaust steam.

In more modern installations greater care has been exercised. Where economy in fuel has received serious consideration, low-pressure steam turbines have been installed to make efficient use of the exhaust from already existing steam engines, and thus provide an economical means of developing electrical power for distribution throughout the colliery.

Economical as this system may appear at first sight, it can only be looked upon as a kind of makeshift; the fact that the most economical prime mover of the present day is the internal-combustion engine must not be lost sight of. Whenever a steam plant is now installed for power-generating purposes at a colliery, the same can only be looked upon as a temporary arrangement if the colliery in the future has to compete with pits equipped with modern power-generating equipment.

Gas Engines Are Suitable

The gas engine is admirably suited for colliery work. In cases where inferior coal is available, it can be used most economically in gas-producers of the recovery type; and where the total power required is considerable, the return for the byproducts reduces the cost of gas to a negligible quantity. Where byproduct coke ovens are employed, the surplus gas can be used to advantage in the gas engine, and, of course, for iron works the most economical use for the blast-furnace gas is in this form of prime mover.

Against all this it will doubtless be argued that the gas from recovery producers can be used for generating steam in boilers to drive steam engines or turbines, and also that coke-oven gas can be used in a similar manner; but the fact is indisputable that gas can be used in internal-combustion engines far more economically than in any other way.

Economical as the generation of power by gas engines proves to be, there is another source by which the overall efficiency can be increased, and that is by the use of boilers heated with the exhaust from the engines. The use of such boilers is now becoming general. They will evaporate, roughly speaking, from 2¼ to 2½ lb. of water per hour per brake-horsepower developed by the engine.

The utilization of coal gas principally from coke ovens having a calorific value of from 400 to 450 B.t.u. is receiving more attention every day, and this gas—although somewhat richer in hydrogen than ordinary illuminating gas—is an excellent one for driving gas engines. It is perhaps somewhat strange that more use has not been made in the past of surplus coke-oven gas, and, generally speaking, of gas engines in connection with colliery work.

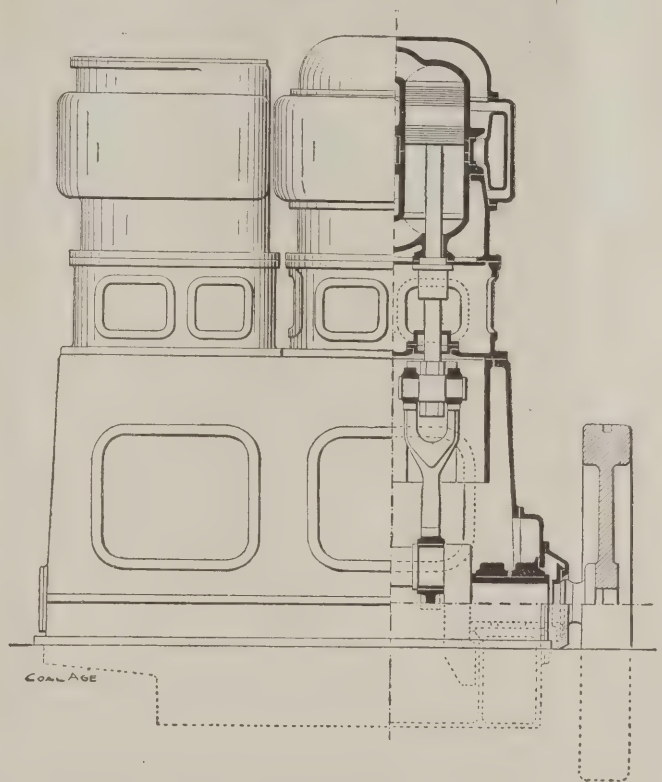

Fig. 1. Part Section of a Valveless Two-Cycle, Vertical Gas Engine

The Experimental Stage Is Passed

Owing to failures during development in the early days, managers still hesitate to install large gas engines. The vertical type has, however, long since passed the experimental stage. It is the one most suited for direct connection to electric generators, owing to the possibility of running at fairly high speeds.

The absolute reliability of the high-speed, forced-lubrication, inclosed steam engine has been demonstrated by thousands of examples: consequently, it is to a similar type of gas engine that the colliery manager will naturally look in the future for driving electric generators in his power station.

One of the weak points in connection with large single-acting vertical gas engines is the frequent necessity

*From a paper by John Davidson on "Development of the Internal Combustion Engine for Power Generation at Collieries," presented on June 4, 1914, at the sixtieth general meeting in London, of the Institution of Mining Engineers.

for cleaning out the cylinders. So long as the pistons are exposed on the underside to the crank case, this difficulty cannot be overcome efficiently, as there is no means of controlling the amount of oil which passes up from the crank chamber.

Another weak point is the burning and failure of the exhaust valves, which require occasional cleaning and grinding-in, and many failures are still experienced because of the breakage of these parts. Another weakness is in the ignition gear, although, generally speaking, it must be admitted that failures from this cause are few and far between, provided, of course, that a modern reliable gear is fitted to the engine in the first instance. From the available statistics one infers that the freedom from breakdown in gas engines is very encouraging, and the weaknesses just mentioned may be looked upon as the only ones that are liable to cause occasional stoppage.

For long, continuous work, an engine which is simple in construction is the one most likely to prevail in the end. The tendency in development has been towards simplicity; but for large powers (owing to the prevalent desire to use air-cooled pistons) multi-cylinder engines, mostly of the tandem form, have found favor among engine builders, although this can hardly be said to be in the direction of simplicity.

If the engines are made on steam-engine lines, with double-acting two-cycle cylinders, the size of the working piston need be only about a quarter of that of the four-cycle single-acting type, and for the same power the strains are proportionately less; both these points are advantages in the case of large units.

In the case of single-acting engines, the pistons are usually called upon to serve as crossheads, and, although they appear to wear exceedingly well, this type will doubtless in the near future be obsolete.

The Type of Engine Favored

The author suggests that the double-acting two-cycle engine—built on substantial lines, which long experience in steam-engine practice has proved successful—will be the one that will ultimately be used by all large vertical engine builders. Representing this type, Fig. 1 shows in part section an engine made by Mather & Platt, Ltd.

The engine referred to is without valves altogether to the working cylinders; consequently it possesses great advantages in the direction of reliability for continuous work. As the engines are built on the two-cycle principle, separate air and gas pumps are required, but these are driven directly from the crankshaft; their valves also are operated direct from the same element in a manner similar to those of high-speed steam engines. Owing to this fact, no gears, camshafts, tappets, or springs are required, and the machine operates as silently as the well known high-speed steam engine.

Accessibility is of prime importance, and in modern engines this point has received most careful consideration. Even in vertical tandem engines we are informed that it is possible to open up and get at the lower piston within forty minutes on a 1000-hp. machine. This speaks very well for the design.

For long, continuous work, it is also of great importance that the bearing and working surfaces should be liberal, and the strength of the parts most carefully proportioned to resist the work which they are called upon to bear. In the type of engine illustrated, the only working parts are the main motion-work, which is of ample proportion, and so arranged that it can be well lubricated without waste of oil, the crank chamber being entirely separated from the cylinders by means of a distance-piece. Scraper-glands are fitted at the top of the crank chamber, as is the usual practice in high-speed steam engines. The oil is thus effectually prevented from being carried up into the working cylinders even by means of the piston rods.

The working cylinders are lubricated by mechanically driven lubricators having a separate pump to each feed. The supply of oil is thus reduced to a minimum. By this positive system of lubrication for the cylinders, it is possible to run the engines over exceedingly long periods without cleaning or any fear of their becoming clogged up with oil. This is a great advantage for continuous work.

As the pistons and piston rods are water-cooled, this does away altogether with the possibility of piston seizure and, as metallic packings are fitted to the piston rods—these having now been brought to a state of perfection equal to those used in steam-engine practice—no fear need be entertained concerning trouble in this direction, and the minimum of attention is required.

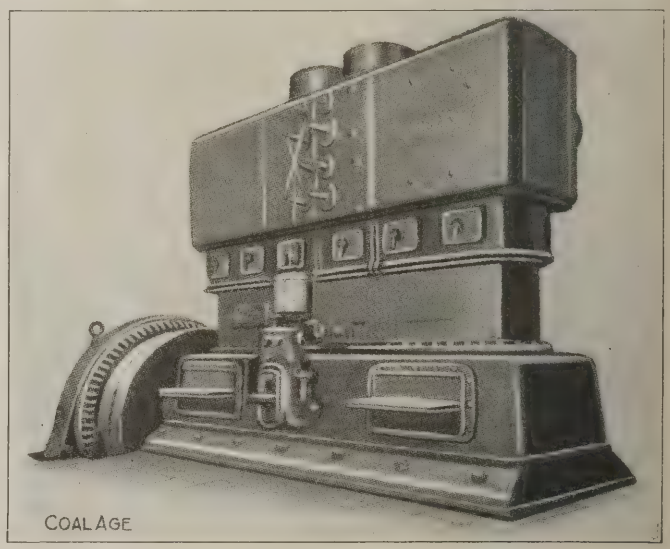

Fig. 2. A 1000-Hp., Vertical Inclosed Two-Cycle Gas Engine

In Fig. 2 is illustrated a 1000-b.hp., two-cycle, vertical, inclosed, forced-lubrication gas engine, which may be taken as typical of the type of machine toward which the trend of development is moving. This engine is built on lines similar to those shown in Fig. 1, all the working parts being lubricated by oil under pressure, and, as the engine is of the double-acting type, the turning moment is precisely the same as that of a steam engine. Owing to the absence of gears, valves and tappets, this four-cylinder engine operates as silently as the ordinary vertical steam engine, and the liberal wearing surfaces, combined with the smooth running of the machine, insure long life.

The Gas Must Be Clean

For continuous heavy service much has been stated with regard to the reliability of the gas engine, but the colliery manager must give careful attention to his side of the business—namely, the production of gas—if he ex-

pects reliability in his prime mover. In the case of boilers, softening plants have often to be installed; in a similar way, in connection with gas-producers and coke ovens, suitable cleaning and purifying appliances must be employed.

Sulphur has to be dealt with drastically, especially where big engines are installed, as in all these cases pistons and rods are of necessity water-cooled. In many instances too liberal a supply of water is used for the pistons, due to the attendants' exaggerated anxiety to feel safe, and acid fumes are condensed on the cool surfaces, causing corrosion. Again, any leakage of water into a cylinder containing sulphurous gas will cause trouble, so that great care should be taken in dealing with this matter. Dust forms another difficulty which requires consideration, but this is one that nowadays causes but little anxiety.

Unwatering a Mine

By I. D. Thomas*

SYNOPSIS—In removing the water from two slopes, two centrifugal pumps mounted on trucks and directly connected to electric motors were employed. These units were lowered as the water receded.

A few years ago a method was employed for unwatering a mine, with which the writer was familiar, that may be of interest to readers of Coal Age.

The mine in question being isolated from any of the other operations of the owners, it was decided that electricity would be the most economical power to use, and current was therefore purchased from a large local power company and transmitted for a distance of four miles at 4000 volts and then by means of transformers at the colliery, stepped down to 440 volts.

From the obtainable data, it was calculated that the property contained at least 100 million gallons of water and was making during the dry season about 800 gal. per minute.

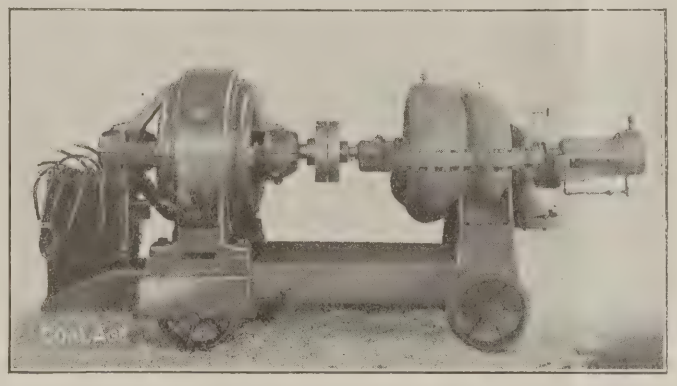

Fig. 1. The Pumping Unit Employed

the horizontal, with pump end down the slope. The pump builder assumed responsibility for the pump thrust and the motor builder responsibility for the motor thrust.

A shelf to carry the compensator was cast integral with the bedplate and the axles were bolted to the bedplate with U-bolts. To the motor end of the bedplate a heavy hitching staple was securely bolted.

To overcome variation in the angle of inclination, a flexible joint was placed next to the suction elbow and to this was fastened, by means of flange unions, a length of 8-in. wrought pipe, on the end of which the foot valve

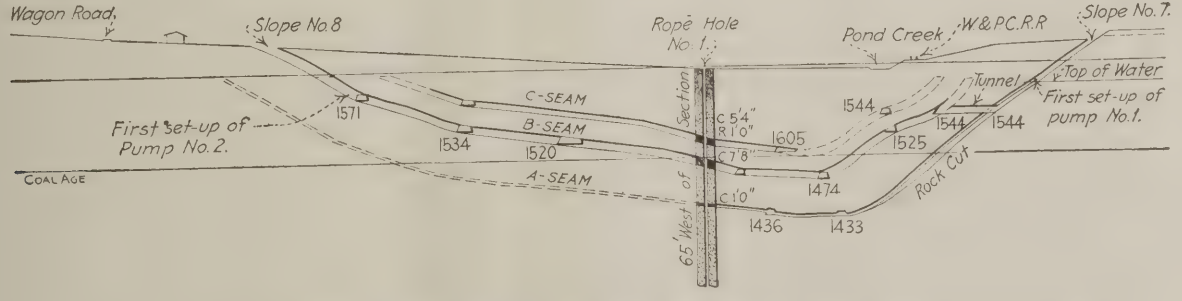

Fig. 2. Cross-Section of the Mine, Showing Successive Positions of Each Pump

On the property were two single-track slopes, one in the "A" or lower vein, driven on the south dip for a distance of 400 ft. to the basin, on an angle varying from 25° to 40°; and one in the "B" vein on the north dip, for a distance of 700 ft. to the basin, at an angle varying from 15° to 27°. Both veins were connected by a tunnel through the intervening strata at an elevation approximately 100 ft. above the basin of the lower or "A" vein; the water standing at a point about 40 ft. vertically below the mouth of the slope. The total head from the basin of the lower or "A" vein was 225 ft. In the "A" vein slope the roads were intact; but had been removed in "B" vein slope when property was abandoned.

The many advantages embodied in the centrifugal pump, chief of which, in considering a proposition of this kind, was its maximum capacity for minimum clearance dimensions, led to the selection of this type of water-lifting apparatus, two of which were purchased for the purpose.

The pumps selected were of the two-stage type, capable of delivering 1000 gal. per min., against a total head of 225 ft. at 1200 r.p.m. These were direct connected by means of flexible couplings to 100-hp. motors, and so designed as to operate at any angle up to 40 deg. from

and strainer were placed. To support the weight of the suction pipe, a small skeleton steel truck, to which this pipe was clamped, was so placed that the weight was properly distributed and strain removed from the pump.

On the discharge end was placed in the order named; an elbow, a valve, an 8-in. wrought-iron pipe, a flexible joint and an 8-in. wood pipe to the surface.

Hoisting equipment having been installed while the transmission line was being constructed, one pump was located in each slope (see Fig. 2) and secured to the hoisting rope and lowered by means of a hoist as the water receded, the suction and discharge pipes being lowered with each pump, extensions to the discharge line being

*Harleigh-Brookside Coal Co., Hazleton, Penn.

put on at the surface. As the compensator was mounted on the bedplate, it was necessary to connect only three wires at each move, this being accomplished readily by the use of tube couplings.

Owing to a deflection of $\frac{1}{16}$ in. in the bedplate, some difficulty was encountered on the first set-up, on account of the inboard bearing heating, but on subsequent set-ups this was entirely overcome by removing the bolts from the coupling connecting the pump to the motor, and carefully leveling the unit by means of wood wedges inserted between the rail and the bedplate, then replacing the coupling bolts.

Eight men were employed in moving pumps, and as many as four moves per day (two for each pump) were sometimes made; the record move having been made in one hour from the time pump was stopped until it was again pumping to the surface. In no instance did relocating require more than three hours, this time being due to meeting obstructions in the slope. The property was entirely unwatered in 30 days.

John Wesley Boileau

Apparently disheartened by the prospect of becoming a hopeless invalid, John Wesley Boileau, a wealthy coal operator and club man of Pittsburgh, Penn., committed suicide by shooting with a heavy revolver on Oct. 7. About ten minutes prior to his death he had informed his wife that he contemplated such a deed. She secured possession of his revolver, and while carrying it to another room for safe keeping, heard the report of another weapon, Mr. Boileau having quite a collection of firearms in his own room.

Mr. Boileau was among the men who have been concerned with the development upon a large scale of the coal-producing fields of western Pennsylvania and West Virginia. Into this work he put a thorough knowledge of science, economics and commercial conditions. He was a profound student of coal-region geology, of the engineering problems involved in coal development, and of the business situation affecting sales of coal properties. So thorough was his knowledge of these matters that he was regarded as an authority by engineers, operators and investors alike.

Mr. Boileau was born Oct. 25, 1873, in Athens County, Ohio. He received his early training in the public schools of Morgan County, Ohio, but has been, throughout his entire life, a zealous student along lines equally scientific and practical.

In 1892, he took a position as clerk in a store, but soon left this to become a teacher, later becoming principal in the schools of Westmoreland County, Penn. In 1895, he took up engineering and contract work, in which he continued to engage for three years. In the meantime, however, he became interested in the coal-land business, and from 1897 onward specialized in this field.

He studied carefully every phase of the coal situation and the problems surrounding the development and sale of coal properties. The scope of his experience, the wealth of scientific knowledge which was his, and his keen sense of values, gained him recognition as an expert in his line of business. He has negotiated several of the largest sales of coal land both to investment and operating organizations that were ever consummated during recent years in western Pennsylvania and West Virginia. He was also identified with various coal and coke enterprises, being an officer and director of many such companies operating throughout western Pennsylvania.

Mr. Boileau had been suffering from ill health following a nervous breakdown for about a year. About a week before his death, he had a fall down the steps of his residence, striking his temple heavily, which rendered him for some time powerless to move. Since that time he complained continually of a pain in his head, until finally he apparently became possessed with the idea that he could never recover.

JOHN W. BOILEAU

Mr. Boileau is survived by his wife, one daughter, and one son, John Wesley Boileau, Jr., also his parents, one brother and one sister.

With Mr. Boileau, the City of Pittsburgh loses a valuable and respected citizen, while the coal industry in general suffers the loss of one of the men who has done much to bring the industry to its present status. It was largely through his untiring efforts and influence that the City of Pittsburgh secured the testing station of the Bureau of Mines.

The Meeting of the American Institute of Mining Engineers

The meeting of the American Institute of Mining Engineers at Pittsburgh on Sept. 8, 9 and 10 was a great success, over 200 members being present. The Institute should be a powerful instrument for good in the coal, coke and petroleum fields, but for years it has been lamentably weak in all.

At the experimental mine a test was made of the Rice barriers, and they proved their value under the conditions to which they were exposed. Exhibits of their mode of action were shown outside the mine, and the visitors watched a cement-gun operator coating a surface with "gunite" reinforced by wire netting, and also inspected the recently completed work of the gun underground.

On the last day a visit was made to the Bureau of Mines where some interesting demonstrations were made, somewhat similar to those shown the Coal Mining Institute of America at its last visit. Next week we hope to give a full account of the meeting.

Small Potatoes

In the issue of Oct. 3, we published a letter from Geo. N. Lantz of New Straitsville, Ohio, on the situation in the coal fields of that state. It seems extremely logical. Hardly anything could be more convincing than his italicized words that: Equal labor demands equal compensation. We hesitate to differ with him. It is hard to place against his moral maxim, a stern economic truth. But here we write a more correct doctrine with a manifest disregard for the good will of those who term economics a heresy. The dictum runs thus: Wherever products are competitive and enter the market on equal terms, equal labor can demand equal compensation only when the products of equal labors are themselves equal.

We will for purposes of illustration imagine a miner's wife in colloquy with a farmer who is trying to sell potatoes. "Shure, thim p'raties aren't near as big as Thompson's and yer price is just as big. When you've pealed your p'raties there'd be nothin' left but the skins!" The farmer has a ready reply, "I have to work just as hard as Thompson to raise those potatoes and it ain't my fault if they're smaller." "Shure," says the good wife, "but it's p'raties I'm buyin', not yer labor. Maybe it ain't your fault thim taters is small, maybe it is, but they're small all the same, an' I'll have none of thim, so yer can carry 'em to Mrs. Smith or the company sture."

It is clear that the farmer must take a lower price than Thompson because his potatoes are less well nourished or a poorer variety. The market is not for his labor, his efforts, his soil fertility, not for anything but for his product and the reward of his labors depends not on his exertions but on what his basket reveals when he removes the burlap. That is the test the miner's wife imposes on his potatoes. The test of her husband's product is no less searching. If his coal contains large quantities of slack, whether he is to blame or not, the whole product cannot sell for as much and there cannot be as much profit in his labor.

Fortunately where the fine coal does not result from the miner's own carelessness, it is usually the outcome of the softness of the coal and accordingly it is frequently the case that the coal which makes the most slack is truly the easiest to mine and the scale which pays attention to the proportion of slack is therefore as morally defensible as it is economically sound.

We object to putting morality against economy for what is economical is usually moral. Surely no man would have a moral right to do work for which he is economically unfitted nor has any man any right to be utilizing material really unsuited for economic use if he makes the public pay for his misjudgment. There is every need that the economic law shall arrest the hand of the man who chooses to produce an inferior article at an excessive cost.

Ohio is paying a high wage scale; the miners, however, by reason of unsteady work are getting lower pay han in almost any state in the Union. So the miners are not profiting. Concurrently, the coal mines of Ohio were only mining 8 per cent. more coal in 1912 than 1907 whereas in the rest of the United States the increase in the output of bituminous coal in that time was 14 per cent. Clearly the Ohio operators were not giving any evidences of prosperity. The Ohio scale pays neither operators nor men.

The wage scale of Ohio has made the state backward in conversation, negligent of first aid, indifferent as to housing and largely unprogressive. If eastern Ohio finally settles down to the 47c. rate for machine-mined coal now demanded, there will still be mining, but the sales will be restricted to a smaller area and work will be intermittent and uncertain. For after all, the moral right to equal pay for equal labor is not recognized by the consumer; the right which appeals to him is equal price for equal product and no other cry appears to have merit.

The American Hermit

The efforts of our papers to boost "Made in America" goods might be looked upon as a distressing manifestation of narrowness had not Englishmen and Germans already shown us the way. It is up to us to have the manhood and the economic sense not to follow their mistaken lead.

Let us bring before our minds the man we really respect. Is he a man who is entirely self-sufficing, who fusses around day by day, doing his own chores, making his own clothes and procuring his sustenance from his own garden patch? Or is he a man who doing one thing or one class of things transcendently well, casts aside all other ends and attends only to such matters as suits his genius and his training best? Is the model of our life, in short, the hermit or the captain of industry?

The most profitable work of the nations of the world is that which they can do best, for which the peculiar conditions of the country fit them. They advance themselves most by performing the largest services. A nation with superlative advantages, such as we may well claim as ours, is foolish to endeavor to enter into competition with foreign countries wherever the struggle is merely equal. Of course, it must be understood that the question of equality will take into consideration transportation as well as production elements as they affect the problem.

Much of the aggressive nationalistic sentiment has, of course, not been unfortunate and it has merely caused the United States to acclimatize trade which should be normally ours. It has sometimes, however, put us in the ambiguous position of a one-armed man who enters himself in a baseball team just to show he is an all-around athlete. But such a desire to outshine in everything is merely vain glorious and the aim of our citizens should always be to seek the fittest trades for America rather than to absorb all trades whether suitable, merely sustainable or wholly unfitted to our conditions.

But those who urge us to be self-sustaining also want us to enter the world's markets, and such trade may be easily proved to be un-American if we accept the specious dicta of those same advocates of a self-sustaining America, for how can we sell goods without accepting any return?

To return to common sense: There is a demand in the United States for the expenditure of capital in many ways where the need for it is most evident and pressing. There are glaring inefficiencies right and left which have existed only because our products have in the past been so cheaply secured that we could afford to be lavish in their use. Where these inefficiencies can be removed and the removal pay good dividends, the capital should be forthcoming to permit it.

Then there are a number of trades which might profitably be established here which so far have not taken root. If they are well fitted for our conditions and can continue existence without subsidies, they should be established even if for a time they need protection and other governmental support. But to bolster up industries economically unfitted to our country is to withdraw capital from those purposes which have a better right to existence and have an equal need of financial support.

The "Made in England" and the "British to the Backbone" campaign has created no few enemies for England in Germany and elsewhere and has probably done absolutely no good because the nation is best served which buys always in the cheapest market and sells in the highest.

Anyone who has traveled around our coal mines will realize that an immense amount of capital is needed to make them economical in operation. Everyone also knows that the coal when it arrives at the market is largely wasted by inefficient use. Plants at the mine and the factory are both too often flimsy structures liable to fire. Money could be better spent in making the changes these conditions indicate than in attempting to build up certain mineral industries which must always be dominated by those abroad or to coax specific products from the soil to which neither our climate nor our fields are fitted.

Selling "Duty" Instead of Coal

There seems a lamentable lack of comprehension of the opportunities existing, exhibited by those operators whose mines are adjacent to brick and other clay-product yards and like industrial enterprises. In most cases brick kilns are heated by grates set around the periphery of each kiln. These openings are extremely weakening, and need constant replacement. Their removal would make for economy.

But the principal objection to their continued use as sources of heat are that they must be fired not with the cheapest kind of slack or refuse, but with run-of-mine coal. As a result the operator who should be helped by the presence of brick yards finds that they demand the same product which is needed for domestic trade. This condition of affairs is desirable neither for operator nor for clay-product manufacturer.

Another difficulty is that the clay-product man has to haul all the coal so used some thousands of feet and to distribute it in untidy little piles around his kilns, where it is often in the way of the wheelers, and, worse yet, it all has to be shoveled so that the kiln tender's work becomes one of drudgery. This drudgery removed, more skilled men could be obtained to do the work with resultant improvement of product.

How much better it would be if we were to generate heated gases at the mines with self-stoking grates, using slack or impure coal and lead some of these gases to the brick kilns and others to the boilers of the coal company's plant. There is no reason why a coal corporation should not provide the heat needed for the kilns at a certain stated figure, say the same rate as that hitherto paid by the clay-working company for coal at the mine. The gain to the clay worker would be derived from the saving in the haulage of the coal, in the cartage of the ashes, in the order of his yard, in the improvement of his kilns, in the reliability of his heat, in the saving of stoking labor and in use of the heat under his own boilers.

The Galena Signal Oil Co. has found it profitable to sell oil not in bulk but on performance. We believe coal can be sold somewhat on the same basis, and to even better advantage, by converting the stored heat of the coal into heated gases before delivery to the consumer.

Pittsburgh-Buffalo Company in Trouble

The Union Trust Company of Pittsburgh proposes to foreclose on the Pittsburgh-Buffalo Company. This will mean that John H. Jones, president and largest stockholder of the P-B Co., will be subjected to the greatest misfortune of his life. He has fought his way up in the coal business, from a humble position in the mines as a lad of ten to the top of the heap, and there is not a man who knows John Jones, but regrets the situation which now faces him.

Mr. Jones is not the kind of man who craves sympathy. He has conducted his own fights in his own way, always observing the rules of the game. However, it does appear to us that the Pittsburgh bankers might be more lenient in their demands on the Pittsburgh-Buffalo Company. Surely the present is not the time to tear down our business structures, if there is the slightest possibility of their weathering the depression created by a world war.

To attempt to sell a coal property now is surely unwise, for no company today could realize anything like a fair price for its holdings. If the Pittsburgh-Buffalo Company is disposed of before conditions have again become normal, the result will be a serious loss to the unsecured creditors.

Mr. Jones and his associates have promised, that if necessary to the full settlement of the company's debts, they will promptly assign their equities in the properties to a syndicate representing the stronger creditors, providing, of course, that the latter will protect those who cannot protect themselves.

Careful investigation by Dr. I. C. White and other prominent engineers discloses that the properties of the Pittsburgh-Buffalo Company are worth several times the debt the company owes. The coal business will improve rapidly when the European trouble is settled and the mines of Mr. Jones and his associates will not only settle their obligations but will pay a handsome return in interest to those who have had faith in them.

We need men like John H. Jones in the coal industry, and we earnestly hope the Union Trust Company officials will accord him a full opportunity to carry his work to a successful conclusion. Whatever the outcome of the present trouble, we predict that Mr. Jones will eventually surmount all obstacles in his path, and will win in spite of every handicap fate may temporarily place in his way.

The Labor Situation

SYNOPSIS—The executive officials of the U. M. W. of A. write the President that if the truce agreement is to be modified for the benefit of the operators, they also desire to make changes in it. The mayor and sheriff in Butte, Mont., have been removed for not protecting the Western Federation of Labor from the violence of the Industrial Workers of the World.

The United Mine Workers of America, through the president, secretary-treasurer and vice-president, have written to the President of the United States, protesting that if the operators are permitted to change the terms of truce, they also should be allowed to make modifications suited to their needs. They are justified, of course, in saying that their approval was accorded to the instrument just as it was presented to them, and in no other form, but their letter, in which they refuse to be bound by a modified form of it, is unnecessary, and even ridiculous.

But we must commend the operators for demanding that assurances be given them that there will be peace when the military forces are withdrawn ,and that the concessions they are required to make shall be reasonable. Their absolute right to protection from violence, for which they are now pleading with an autocratic President, should not be purchased at a high and arbitrary price set by a commission one of the two members of which has been employed to stir up strife against them. The operators most reasonably object to the figure at which they are to be ransomed from the violence of the agitators, especially as they are almost sure that even compliance will not assure safety.

The Miners' Statement

We publish below the statement of the miners:

We have learned through the press reports and otherwise, that the coal operators of Colorado have asked for certain modifications of the basis for a three-year truce of the mining trouble in Colorado, recently proposed by you.

Our acceptance of your proposal was based upon the assumption that it would likewise be agreed to without change by the coal operators.

There are certain features of the agreement which we, too, would like to have modified or changed. We did not ask for this because we felt that the occasion required full compliance with your very earnest wish. Our position now remains the same as when we forwarded you our letter of acceptance. We are willing to abide by the proposed basis of adjustment submitted by you.

If, however, there are to be modifications of any sections of the proposed basis in order to meet the requirements of the coal operators of Colorado, then we, too, ask the privilege of requesting a change in certain sections thereof.

We ask, in the event of any change, that we be given the opportunity of presenting our objections to certain features contained therein with a view to having them changed or eliminated altogether.

We repeat our acceptance of your proposed basis of settlement without change, providing only that the same will be agreed to by the coal operators of Colorado in like manner.

The quiet now pervading Colorado may perhaps make people think that the withdrawal of the troops will not cause violence. But there is no reason for such assurance while the men who have caused it before still remain on the ground, and, by the terms proposed, are assured of a place in the mines if the slowly acting courts do not intervene and exempt them from employment by declaring their criminality. Early in September, Roy Faddyoff, a private in Troop L, 11th United States Cavalry, was killed and his mangled body was found on the Denver & Rio Grande R.R. tracks. It is thought that he was attacked by strikers and killed while on guard, but, so far as we know, no one has yet been apprehended.

According to later reports, the President is intending to remove the United States troops as soon as the state militia is ready to replace them. We hope he will make provision of this sort, and will, moreover, first assure himself that the strength and financial support of the militia is adequate for a long campaign.

Contrast Between Conditions in Montana and Colorado

As a result of the recent rioting, the operators of the copper mines at Butte, Mont., have decided to operate their mines open shop. So the Western Federation of Miners is about to be beaten again, and as this defeat follows its surrender at Calumet, Mich., the affiliation of the W. F. of M with the United Mine Workers of America will be of no great benefit to that body.

It is interesting to note how different has been the action of the militia in Montana to that in Colorado. The soldiers in Butte have most methodically cleaned up the town, and their drastic action is due, we think, wholly to the fact that they have the union men in full sympathy with their aims. For far less activity in Colorado, General Chase was condemned in most unsparing language. So far from withdrawing United States troops before complete pacification, the administration, without even being asked for assistance, as prescribed by the constitution, moved federal troops to Fort William Henry Harrison, near Helena, Mont., from Fort Wright, Wash., so as to be prepared for every eventuality.

Ohio, Still Quiet, Hopes for Colorado Settlement

Quiet reigned in all of the mining districts of the Buckeye State during the past week. No moves have been made by either side of the controversy in eastern Ohio towards renewing scale conferences. The operators are content to leave matters rest as they are, and the miners are not yet disposed to sign up on the proposition of the operators, which is 44.61c. for machine-mined coal on the mine-run basis. This is the same as the Pittsburg scale. It is claimed that many of the rank and file of the miners' organization would be willing to sign up on that proposition, but they are prevented by the union officials and the policy committee.

William Green, secretary-treasurer of the national organization, visited eastern Ohio last week in a reported effort to borrow money with which to pay further benefits to the striking miners. Some benefits have been paid recently in store orders, and these have caused some dissatisfaction among the men, as they would prefer money. The difficulty in financing the strike will continue until the day when the Colorado troubles come to an end.

No developments of consequence have taken place in the Coshocton field, where the men are still out.

The Ohio Industrial Commission reports everything quiet in the fields where mines are in operation. The commission has not been called upon recently to make any special rulings as to the percentage of slack or the percentage of impurities allowable.

It is rumored that Industrial Workers of the World forces are again preparing to invade the eastern Ohio coal district, although their efforts at agitation among the striking miners were unsuccessful during the summer. The agitators believe that the situation is more favorable to their efforts, for the men have been longer away from the mines, and an appeal to disorder now will be more effective than at the beginning of the strike.

The Southwestern Coal Fields

A condition of peace prevails throughout the Southwestern coal fields; not a single strike is now in progress, and such minor troubles as arise are being straightened out with celerity. J. B. White, president of the United Mine Workers of America, who was in conference in Kansas City, Oct. 8, with officials of the operators' associations, in reference to contract matters, expressed himself as well satisfied with the outlook. Mr. White has in recent cases of complaints taken immediate steps to get the men to return to work, and they have responded quickly. The result of inquiries has disclosed that the shutdowns have been caused by misapprehensions, which are removed by a better understanding of the contracts.

W. L. A. Johnson, commissioner of the Southwestern Operators' Association, returned recently from Fort Smith and McAlester meetings, where he assisted in the organization of joint boards, one each for the states of Arkansas and Oklahoma. He reports conditions are very satisfactory.

Validity of Labor Organization

The Hitchman Coal & Coke Co., on behalf of the West Virginia coal operators, desired the Supreme Court, on Oct. 13, to review the action of the Fourth United States Court of Appeals, reversing the decision of Judge Dayton, who ruled that the United Mine Workers of America was an unlawful organization.

Judge Dayton, in the Federal District Court, enjoined W. B. Wilson, the present secretary of labor, and other officials of the United Mine Workers of America from attempting to unionize the mines of the Hitchman Coal & Coke Co. The labor leaders have endeavored to have Judge Dayton impeached.

The coal company has no absolute right to the review desired, but asks the court to exercise its discretion and grant the reopening of the case in recognition of the importance of the question involved.

Sociological Department

Concrete City in Bloom

Flowers of all colors are blooming in the flower pots around the trim houses of "Concrete City," the Delaware, Lackawanna & Western's model village near its big Truesdale Colliery. They are blooming too in the first and second story window boxes, and last month two officials of the company awarded first, second, third and fourth cash prizes for the best and neatest gardens and grounds.

John P. Evans carried off the first prize of $10, John Allen drew $5 for second prize, John Martin $3 for third prize, David J. Thomas $2 for fourth prize, and Benjamin Isaac secured honorable mention. But it was not so much the value of the prizes as the value of the improvement to their surroundings that made practically every householder in "Concrete City" enter the competition.

The New Swimming Pool

And this was not the only improvement in "Concrete City" this summer. A circular swimming pool with constantly flowing water has been installed in one corner of the big central square, and on hot afternoons many of the children, some in improvised swimming costumes and some with the alarming lack of them that characterizes New York newsboys when they make a surreptitious dash into the fountain in City Hall Park, disport themselves in safety in its shallow waters, for there are between eighty and ninety children in "Concrete City."

The village was started last summer and was described at length with illustrations in Coal Age, in Vol. 3, pp. 851-854. Twenty double houses were constructed around a big central square 300x410 ft. They are two-story structures 50x25, with flat roofs, dark green trimmings and little red chimneys which make an agreeable spot of color. The houses are practically of solid concrete, molded in one piece, after the idea of Thomas A. Edison, but built according to another man's patented adaptation of Mr. Edison's idea. Floors, walls, ceilings, stairways, even sinks and wash basins, are made in a mold of

A Street in Concrete City

A Prize Winner at the Recent Contest

A Yard Which Received Honorable Mention

"poured" concrete. The construction is such that, on occasion, the furniture may be removed and an entire house thoroughly washed out with a hose.

Each house contains eight rooms, and has stationary wash tubs, a buttery and a good dry cellar. The concrete is slow to heat, and the houses are as cool in summer as they are warm and dry in winter. Special precautions have been taken to prevent dampness. Little marquises supported by chains overhang the front steps, which have flower boxes on each side. A complete sewage system has been installed, and the square is bounded by shade trees and concrete walks which also lead to the front and side doors of the houses. The whole city is surrounded by a stout wire fence.

Many Facilities and Cheap Rents

There is much kindly humanity in the forethought which was expended on the interior fittings of the houses. Wooden strips are imbedded in the concrete floors so that carpets may be tacked down. Below the French windows, opening outward, window boxes for flowers are set in the walls. Window openings are generous, and there is plenty of light. The window and door frames and the doors themselves are of wood. There is ample space behind each house for a truck garden, and space in the cellar to keep a supply of coal.

The rent of these houses is $8 a month for single houses, and $16 for the two halves, or a double house. After the cost of administration, taxes, upkeep and improvements on the property such as sewers, grading, concrete walks and shade trees are paid, the income from it amounts to about 3½% on the investment. That the mine workers are not unappreciative is shown by the remark of a miner's wife:

"I paid $12 a month for a house not half as good as this over in Pottsville," she said. "The children are healthier here, the house is perfectly dry and cool, and it is easy to keep clean."

How It Pays the Company

The man in the best position to judge of the value of this model village is the foreman of the Truesdale Colliery, where the dwellers in "Concrete City" are employed. When asked if he thought it was a good investment, he replied:

"If all the people working at Truesdale were like the people living in those houses, it would be much easier for me. Labor which has to come here by an early morning work train is much harder to handle. The houses attract the better class of miners who live in them happily and contentedly. We rent them at such a cost that we make no financial profit, but I wish I had a hundred more of them."

The Children's Paddling Pool

Additional Men for the Rescue Stations

The Mine Rescue Station Commission of the State of Illinois, at its meeting at Springfield, Sept. 25, authorized the Manager, Oscar Cartlidge, to make arrangements with five additional men at each station—LaSalle, Springfield and Benton—to take training in mine-rescue and first-aid work not less than one hour a week at 50c. per hour, with a minimum of $1 per week compensation. While actually engaged in fire fighting and rescue work, the compensation of these men will be $1 per hour.

The men selected for this work must submit to a thorough examination by a physician, and agree in writing to respond to a call from the station at any time, day or night.

This resolution contemplated that each of the station superintendents and assistants should keep in training with their men, and be fit at all times to organize and lead their teams in recovery work. In this way, the Commission expects to be able to offer to the mining interests of the state the most thoroughly organized and efficient of rescue teams.

Discussion By Readers

Method of Working Underlying Coal Seam

Letter No. 4—In reply to the inquiry of G. E. Lyman, COAL AGE, Aug. 29, p. 357, I would say that there need be no fear of serious trouble arising from the overlying abandoned seams in this case, unless the abandoned workings contain a considerable accumulation of water or gas.

I agree with Mr. Lyman's suggestion that the best method to adopt is the retreating system, for mining the coal in the lower seam. The retreating system is, of course, expensive at the start; but, in the long run, it is by far the cheapest method to employ. It may often be necessary, however, owing to a limited capital, to consider the high first cost and to adopt a method that will allow quicker returns on the investment. With the exception of the longwall method of mining, which I do not consider practical in this case, the retreating system will produce more coal to the acre than any other system.

Assuming that the seam is level, I would adopt the double-entry system of mining, and split the air for each pair of crossheadings if there is much gas present. All headings and rooms should be driven on sights, so that the pillars left between them will be of a uniform thickness. When drawing back the pillars between the rooms, the inside ones should be kept, say from 10 to 20 ft. in advance of the next pillar outby. The work should be so arranged that before each pillar is drawn back to the heading, the corresponding pillar on the next pair of entries should be started. By this means, there will be less danger of coal being lost.

With proper care in the setting of posts in regular rows and a uniform distance apart, much timber can be saved. The number of rows at the face and the distance of the timbers apart will depend on the nature of the roof; but there should never be more than from four to six rows of posts, at the most. Great care is necessary in the drawing of timber, in pillar work, to insure the greatest safety. I would suggest that the fireclay underlying this coal can be utilized to advantage for the making of good brick.

It is possible that, as the work nears completion and the mine is soon to be abandoned, it will be an advantage financially to double-shift the work, so as to shorten the time during which there will be an ever increasing expense and a decreasing output of coal.

The Practical Working of the Mine-Run System

Referring to the recent discussion of the working of the mine-run law in Ohio, the following sample letters will be of interest as illustrating some of the difficulties encountered in operating under this law and making the change from the screen-coal to the mine-run basis of weights and payments. Most of our mines have already experienced the problems discussed in these letters, the most of which are actual copies with the omission of the names of the parties sending and receiving the same:

Mr. ————, Weighmaster,
————, Ohio.

Dear Sir:

For your information, we submit the following figures:

Mine weights as shown by your sheets for the month of July, total, 29,894 tons.

Railroad weights for July, 29,260 tons .

You will note that the difference of 634 tons, between these weights, is a dead loss to us; and, at the present state of the market, represents a deficit of $570.60. It is needless to say that we would consider this amount a good profit on the coal. We cannot understand why a difference of this magnitude should exist and ask that you do your best to reduce or cut out this difference, in the coming month. Please do not misunderstand us; we only ask that you weigh the coal as closely as possible.

———— Fuel Co.,
Per ————, Sec'y.

Another letter reads as follows:

Mr. ————, Sec'y.,
———— Fuel Co.,
————, Ohio.

Dear Sir:

I am in receipt of your letter regarding the difference between mine and railroad weights for July. I beg to submit the following as a few of the possible reasons why a difference of greater or less magnitude should exist between the weigh sheets and the railroad weights:

1. Boney coal thrown out and not docked.
2. Coal used for fuel for boilers.
3. Coal lost in transit, or shrinkage due to the drying out of the coal on exposure to the air.
4. Low estimated average on mine cars.
5. Defective mine or railroad scales.

In reference to these possible causes, permit me to state the following:

1. The entire force of coal trimmers works every Sunday, cleaning up tracks and removing unsalable coal thrown out during the week. It is estimated that the amount of coal thus discarded by the trimmers will average 30 tons per week. As the miner is not docked for less than 100 lb. of dirty coal, it is apparent that much of the coal thrown out will not show on the weigh sheet. I estimate the coal thrown out and appearing on the weigh sheet will not average over one-half ton daily; or, say 3 tons a week.

2. The coal used for the boilers amounts to two or three cars each day. The exact weight of this coal will be found in the upper right-hand corner of the sheet. It may be that no allowance has been made for this coal, which would considerably reduce the shortage.

3. The shrinkage of coal in transit is due to two causes: (a) Loss due to the drying out of the coal, which is not inconsiderable. (b) Loss due to robbing, which will depend on the number of families on good terms with the trainmen; and the occasional robbing of cars for engine use or pumping stations.

4. In the present case, the shortage cannot be due to a low average on mine cars. This average was taken from cars that had been standing in the mine throughout the suspension and were heavier than cars in daily use. This average was so high that the checkweighman insisted on a new average being taken recently, which reduced it from 1830 to 1742 lb.

5. It is our custom to test the mine scales frequently, and these are invariably found to be correct. The matter of the correctness of the railroad scales is merely suggested.

We hope to reduce the shortage this month, in respect to the first three causes mentioned; but as to the rest I can suggest no remedy. I do not understand that you request any juggling of the scales to make the mine weights correspond more closely with the railroad weights; and to employ such a means would be foreign to my desire. I want to give a fair just weight both to the miner and to the company.

————, Weighmaster.

In connection with this correspondence, it is worthy of note that, under the screen-coal basis, the percentage of loss was estimated on the railroad weights, which procedure would not reveal the losses from the first three causes mentioned in the letter. It is possible that working on the mine-run basis, operators will need to figure on a larger percentage of loss, because it is not possible to entirely eliminate these causes.

The reply to the last letter, above, reads as follows:

Mr. ————, Weighmaster,
————, Ohio.

Dear Sir:

After carefully considering the items mentioned in your last letter, I have been able to account for 365 tons of the shortage previously named. This still leaves a shortage of 269 tons. Refering to your suggestion as to "juggling the weights," I have no such desire nor would I consent to such a proceeding that would mistreat the miner. What I desire is a correct weighing of the coal and the reducing of the shortage mentioned, as far as this is possible.

————, Sec'y
———— Fuel Co.

Another letter reads as follows:

Mr. ————, Sec'y.,
———— Fuel Co.,
————, Ohio.

Dear Sir:

Referring to our previous correspondence in regard to coal shortage, I have been carefully going over the entire matter and believe that I have discovered what may be a large source of error and loss. In examining closely a few of the empty trips, before they were taken back into the mine, I discovered that a considerable amount of coal was left in many of the cars. I have drawn the attention of the dumper to this fact, and he admits that he has been careless in the matter. In the future, greater care will be exercised in dumping the cars, and a close watch will be kept of the empty trips to see that all the coal has been dumped. I believe that this will eliminate much of the trouble in the future,

I will be glad to have you mail me the mine and railroad sheets for the last month, so that I can compare these and see what progress we are making in reducing our shortage.

I am also endeavoring to ascertain how closely we are loading the cars to capacity, and am keeping a daily record of the capacity of all cars loaded, together with my tonnage. I would like to know what percentage of overweight is reported on these cars.

————, Weighmaster.

The above letters show a persistent and determined effort on the part of the weighmaster to reduce the reported shortage of coal between the weigh sheets and the railroad sheets. It is not strange to find that the July shortage of 634 tons, which was later corrected to 269 tons, was reduced in August to 142 tons; and, further, that the September report showed only a shortage of 28 tons, which was considered as a satisfactory record.

A MINE SUPERINTENDENT.

————, Ohio.

The Foreigner in Mining

Letter No. 6—If the remarks of I. C. Parfitt, COAL AGE, Sept. 12, p. 440, were true, the coal operators of eastern Ohio would have to close their mines. I have faith to believe, however, that this is far from being the case. If it were true that a protracted stage of adolescence was necessary for the development of a foreign miner, the coal industry would not have shown the growth and prosperity that has marked recent years.

Looking backward from our present viewpoint that makes a fair perspective possible, it seems to me that these foreigners have shown great adaptability and made wonderful progress in learning the language, customs and habits of the American people and the methods employed in coal mining. It may be true, in isolated cases, that foreigners do so "regard liberty as unrestricted freedom for the indulgence of the animal propensities of primeval man." But, if this were true, generally, it would not be possible for me to sit here and write these lines, while hundreds of such a class of beings were all about me.

Further, at our mines, 2 miles away, equipped with large tipples, expensive power plants, five locomotives, fifteen machines, pumps, fans, mules, etc., etc., not a thing has been touched; and watching has cost us less than $50 per month. To my knowledge there has not been a gun on the premises, since Apr. 1 of this year. Again, during the strike of nearly six months, with over 10,000 of these foreigners, hereabout, there has not been a single violent death and very little violence of any kind whatsoever. Compare this, if you will, with newspaper files of 25 years ago, when Americans and English-speaking people predominated; and then say whether these dominant characteristics and this type of civilization cannot be easily assimilated.

It is true, also, that at the recent convention of operators and miners, at Wheeling, W. Va., these foreigners showed utter disrespect for their employers, and often shook the finger of scorn over them; until, finally, the mine owners decided to withdraw from the convention and submit their propositions to the miners. In the hotel lobby, the miners' attitude was charged to "the I. W. W.," to "state politics," to "labor leaders," etc., etc., but, I would ask, are these several influences actual causes, or are they the effects of conditions that have failed to properly develop and educate this class of labor.

These turbulent, irate, hard-headed foreigners were once smiling immigrants, courteous and easy to please. We may ask, "Has the coal-mine owner made the slightest effort, in many cases, to shape this raw material; and, if not, why should he be surprised to observe an abnormal growth among them. Has the mine owner, in many cases, interested himself in the welfare and surroundings of the foreigners in his employ? Has he shown any interest in them or made any attempt to understand them?

Is it not a fact that, in many cases, the coal operator has regularly impressed *one* thing only upon his superintendent; namely, that the "cost sheet" was everything in the world worth consideration. As a result, in the large majority of cases, these men have been styled "hunks," "Dagoes;" and designated by numbers to avoid even the trouble of learning their names. Whenever the mine boss has found the brusque manner and gruff voice, the easiest way to handle this class of labor, he has prepared the ground for the radical leader to sow his seeds of dissatisfaction; and the crop has been already all that could be expected. It will, now, be a herculean task to wrest the power from these leaders; but an educational campaign and an earnest attempt to improve the surroundings at the mines, backed by the personal touch of the owner, superintendent and foreman will eventually mold sentiment and pave the way to better results.

The minimum wage, shorter hours and other questions are coming; and if the operator expects even a respectful hearing he must do his part to cultivate a better sentiment among his foreign employees. Again, competition in the coal industry will soon cause efficient engineering to replace obsolete methods; and the foreman who depends upon a brusque manner and an extensive vocabulary will

be discounted by the one trained to handle electricity, mechanics, mining methods and human nature, successfully.

While trained men and improved methods are generally forging ahead, I know mining properties in eastern Ohio and elsewhere that have made no progress during the last 15 years. On these properties, one cannot find a labor-saving device or a machine designed later than 1900. A manufacturing concern could not follow such an example and live. Many coal-mine operators have been so engrossed in their sales department and other matters, that they have given no attention to the introduction of mining machines and other improvements; but have received the suggestions of a superintendent, in this regard, very much as the average farmer receives the proposals of a lightning-rod agent.

J. D. Jones, Supt.,
Glen's Run Coal Co.

Dillonvale, Ohio.

Letter No. 7—I have been deeply moved and profoundly impressed with the generous expressions that have marked nearly all of the letters of our mine foremen and superintendents, in respect to the attitude they advise and which they themselves are striving to maintain toward the ever-growing numbers of foreigners seeking and finding employment in the coal mines of this country. Nothing presents a more hopeful aspect, and more certainly promises the ultimate triumph of successful mine management, over the present baneful influence of most so called "labor leaders," who are, in fact, widely recognized as "agitators"—trouble makers instead of peace makers.

No one denies the right, the legal and moral right, and the peculiar advantage to be gained by organization. Labor has the same right to organize as is accorded to employers of labor. Organization properly conducted and controlled is the foundation of successful industry. It must be recognized, however, by all members of organizations, that the free and unrestricted voice and will of the members is the guiding hand in every transaction. A so called leader is, in most cases, a disturbing element. Let men act on their own best judgment and give them freedom of expression; and the *get-together* spirit will eventually prevail and harmony take the place of discord.

To this end, let every mine superintendent and mine foreman "bubble over with the milk of human kindness" and lose the "brusque manner and extensive vocabulary" so often employed in dealing with the foreigner.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

Action of a Reciprocating Pump—The piston or plunger of a reciprocating pump, by its movement to and fro in the pump cylinder or barrel, alternately fills and empties the same with water. By means of suitably arranged valves, the water that enters the cylinder by one port is entrapped by the closing of the valve over that port, and is then forced out through another port into the discharge pipe.

Piston Displacement, Theoretical Capacity—The space through which the piston moves represents the volume of water pumped, making no allowance for leakage or **"slippage."** This volume is called the "piston displacement," and is reckoned in cubic feet per stroke, or per minute.

The piston displacement is the theoretical discharge of the pump or its "theoretical capacity," usually estimated in gallons per minute. The actual discharge is always less than the theoretical, owing to leakage of valves and packing, and the slip of water past the piston.

Efficiency of Pumps—In respect to the capacity of a pump to deliver water, its efficiency is the ratio of the actual discharge of the pump to its theoretical capacity. In all pumps driven by a motor or engine, this is called the efficiency of the **"water-end."** In good pumps, the water-end efficiency ranges from 80 to 85 per cent.

PUMPING CALCULATIONS

Let d = diameter of cylinder or plunger (in.);
l = length of stroke (in.);
n = number of strokes per minute;
S = piston speed (ft. per min.);
G = water pumped (gal. per min.).

Piston speed, $$S = \frac{n\,l}{12}$$ *(ft. per min.)*

Piston displacement, $$\frac{0.7854\,d^2 l}{1728}$$ *(cu.ft. per stroke)*

Piston displacement, $$\frac{0.7854\,d^2 S}{144}$$ *(cu.ft. per min.)*

Theoretical capacity, $$\frac{0.7854\,d^2 n l}{231}$$ *(gal. per min.)*

Effective Head in Pumping—As previously mentioned, when a pump is in operation, the total effective head (h_1) is equal to the sum of the gravity head or vertical lift (h), the friction head (h_f) and the velocity head (h_v). Hence, adding these expressions (see Flow of Water in Pipes) and simplifying, we have as follows:

Effective head, $$h_1 = h + \frac{G^2}{800\,d^4}\left(\frac{h}{d} + 2.08\right)$$

Whenever the diameter (d) of the column pipe, in inches, does not exceed its length in hundreds of feet, the velocity head can be ignored with slight error, which is less than 2 per cent. of the friction head; and the formula becomes:

Effective head, $$h_1 = h + \frac{G^2 h}{800\,d^5}$$

The Coal Age Pocket Book

Pressure Required in Pumping—In a direct-acting steam pump, the total pressure in the steam cylinder must equal the total pressure in the water cylinder.

Assuming, first, that the diameter of the steam cylinder is equal to that of the water cylinder or plunger, the pressure per square inch in the steam-end (p_s) must equal that in the water-end (p_w), the latter being calculated from the effective head (h_1). Hence,

$$p_s = p_w = 0.434\,h_1$$

In order to avoid excessive steam pressures required for high lifts, it is necessary to increase the diameter of the steam cylinder so that its area will bear the same ratio to the area of the water cylinder or plunger, as the water pressure does to the desired steam pressure, which gives the following

Rule—The area ratio or the square of the diameter ratio is equal to the inverse pressure ratio. Or the diameter ratio is equal to the square root of the inverse pressure ratio.

Or, expressed as a formula, calling the diameters of the steam and water ends of a pump d_s and d_w, respectively, and the corresponding pressures p_s and p_w,

$$\frac{p_s}{p_w} = \left(\frac{d_w}{d_s}\right)^2; \quad \text{or} \quad \frac{d_s}{d_w} = \sqrt{\frac{p_w}{p_s}}$$

Horsepower Required in Pumping—The power required in pumping is estimated from the weight of water to be lifted a given height, in a given time, which gives the work to be performed, in foot-pounds per minute. A common rule is to assume that this effective work per minute is 60 per cent. of the required power of the pump. This rule is, however, only approximate.

The only safe method of calculating the power required to pump any number of gallons (G) of water per minute, to a given height (h), in feet, is to first calculate the effective head (h_1), and multiply this by the weight of water to be pumped per minute. The product obtained will be the foot-pounds of effective work required. To find the required horsepower of the pump, it is necessary to know the efficiency of the steam-end.

The efficiency of a pump, in respect to work, is the ratio of the work performed per unit of time to the power consumed. In other words, it is the ratio of output to input for any given period of time, or the mechanical efficiency of the system taken as a whole. The efficiency of the steam-end of a well designed direct-acting pump will range from 75 to 80 per cent.

Then, assuming an efficiency of, say 75 per cent. for the steam-end, divide the effective work by 0.75 to obtain the gross work to be performed. Finally, divide this result, again, by 33,000 to find the required horsepower of the pump.

Or, expressed as a formula, the horsepower (H) required to pump a number of gallons (G) under an effective head (h_1) is

Horsepower required, $$H = \frac{62.5 \times 231\,Gh_1}{0.75 \times 1728 \times 33{,}000} = 0.00034\,Gh_1$$

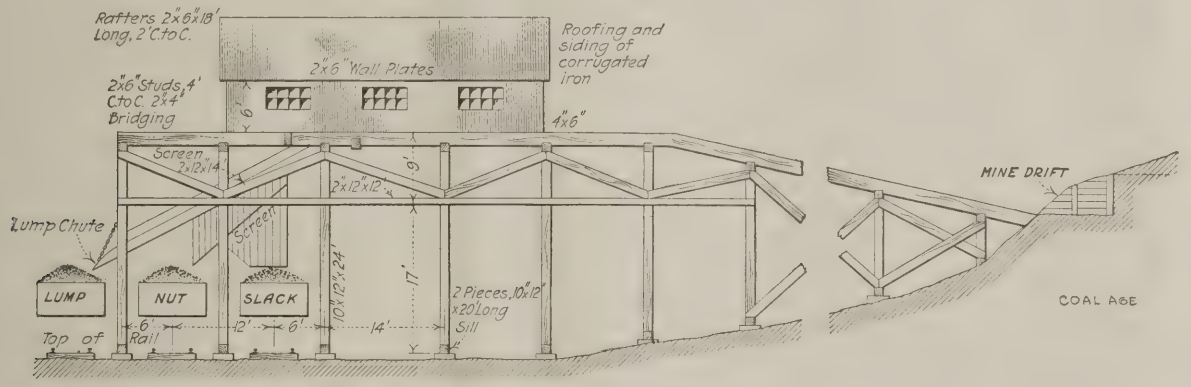
Inquiries of General Interest

Cost of Opening a Drift Mine

Can you inform me as to the probable cost of opening a coal mine, or assist me in securing data, in this regard, that will be of value? The coal is bituminous and outcrops on the face of the hill. A trestle will be required to reach the railroad, where the coal is loaded into the cars. I desire to obtain information in reference to the cost of opening the mine, its equipment, and the material needed in the construction.

A discussion of this subject by readers who have had experience along this line would be helpful and interesting.

JOHN N. SHANNON.



Crafton, Penn.

We agree with the writer of this inquiry that reliable data, giving the cost of material and labor required for the opening of a small mine, would be both interesting and helpful to those contemplating such work. It is readily understood that such data can be only suggestive in their application to a given case, since the cost of labor and material will vary widely in different localities; while the cost of development, in mining work, must be wholly determined by the conditions governing the proposition, in relation to geological features, the size and importance of the undertaking, desired output of coal and other requirements. Notwithstanding these differences, however, such data always have a relative value that makes them an important guide in the estimate of new work; and we hope that such estimates of cost will be forthcoming from readers of COAL AGE who can supply them.

As a suggestion along this line, we present the accompanying diagram, showing a few of the details of construction of a tipple and dumphouse for a drift mine. Three railroad cars are shown under the screens, being loaded with lump, nut and slack. The lump-coal car stands on a platform scale and the weigh beam is in the dumphouse on the tipple. The diagram illustrates the tipple arrangement, in elevation, at an actual drift mine; and the following estimate made in that case shows the approximate cost for material and construction.

ESTIMATE OF LUMBER REQUIRED

	Pcs.	In.	Ft.	Ft. B.M.
Bents, cross-sills	8	6x16	12	768
Sills	6	12x12	20	1,440
	2	12x12	14	336
	1	12x12	16	192

SHOWING ELEVATION OF A TIPPLE DUMP AND WEIGH HOUSE FOR A SMALL DRIFT OR SLOPE OPENING

ESTIMATE OF COST FOR LABOR AND MATERIAL

Say 21,000 ft. b.m. at $14 per M.		$294
Framing and erecting, 21 M. at $10 per M.		210
Windows, 10, 8-lt., 10x12-in., at $2.50		25
Iron, nails, 60d., 1 kg. at	$3.50	
20d., 1 kg. at	3.50	
3d., 1 kg. at	4.00	
Boat spikes, 5x⅝-in., 1 kg. at	5.00	
Wrought-iron washers, 1 kg	5.00	21
Tipple horns, in place, 2 pr		50
Roofing, corrugated, 16 squares at $2.25, laid		40
Screens, lump, 6x10 ft., in place	$75.00	
Screens, nut, 6x6 ft., in place	25.00	100
Chute lining, ¼-in. boiler plate, laid		60
Loading apron		15
Plates, upper landing, ½-in. boiler plate, laid		125
Tracking, 20 lb. tee iron, 6 cwt., laid		10
Track scales, in place		600
Blacksmith shop, 20x24 ft.		100
Office, 20x32 ft.		150
Fan, engine and housing		1200
Mules, four at $125		500
Superintendence and incidentals		500
Mine cars		1000
Total		$5000

The above estimate is for the tipple and track scales only. It includes cost of labor and material, but does not consider the cost of opening the mine or the necessary equipment for its operation, further than providing the necessary equipment for ventilation and mule haulage in the mine.

Examination Questions

Questions Asked That Cannot Be Answered

(Selected from Different Examinations)

NOTE—The following questions have been taken at random from different state examinations and are given here as examples of the lack of technical knowledge displayed by members of examining boards, from time to time, by the questions they ask or the answers assumed by them to be correct.

QUES.—If a pump having a length of stroke of 3 ft., working 15 hr. a day for 5 days, empties a mine of water, what must be the length of stroke of another pump, working 10 hr. a day for 12 days, to perform the same work, the stroke of the former pump being performed four times as fast as the latter?

This question is incomplete, inasmuch as the diameters of the two pumps are not given. In order to answer the question, the candidate must assume that the diameter is the same in each case.

For example, making that assumption, it is observed that the first pump runs $5 \times 15 = 75$ hr., while the second pump runs $10 \times 12 = 120$ hr. in performing the same work; but the second pump makes four strokes while the first pump is making one stroke. But, to perform the same work, other conditions being equal, the length of stroke required must vary inversely as the speed of the pump, and inversely as the number of hours the pump is in operation. In other words, in this case, the ratio of the length of stroke is equal to the inverse speed ratio multiplied by the inverse ratio of the time in hours. Thus, calling the required length of stroke of the second pump x,

$$\frac{x}{3} = \frac{1}{4} \times \frac{75}{120} = \frac{5}{32}$$

$$x = \frac{3 \times 5}{32} = \frac{15}{32} ft.$$

The practical absurdity of this answer shows, at once, the incompleteness of the question asked; because, the required length of stroke of the second pump is less than 6 in., while the length of stroke of the first pump is 3 ft. These pumps, evidently, could not have the same diameter; and the question, as it reads, cannot be answered.

QUES.—If 20,000 cu.ft. of air per minute is passing through an airway with 3.15 hp., and the quantity is increased to 40,000 cu.ft. per min., what will will be the water gage?

This question is incomplete, because it admits of two answers, either of which would be correct, depending on the conditions assumed by the candidate. The examining board gives but one answer as correct. The possible solutions of the question are as follows, the first being assumed by the examining board to be the correct answer:

First Solution

Assuming the given horsepower is the power on the air, the effective work is $u = 3.15 \times 33{,}000 = 103{,}950$ ft.-lb. per min. The pressure producing the circulation is,

$$p = \frac{u}{q} = \frac{103{,}950}{20{,}000} = \textit{say } 5.2 \textit{ lb. per sq.ft.}$$

This pressure corresponds to a 1-in. water gage. Then, since the pressure varies as the square of the quantity of air in circulation, the pressure required to double the air volume in this mine, or to pass 40,000 cu.ft. of air per minute, will be $2^2 = 4$ times the pressure required to pass 20,000 cu.ft. per min. Therefore, the required water gage, in this case, is $4 \times 1 = 4$ inch.

Second Solution

On the other hand, suppose the increase of air from 20,000 to 40,000 cu.ft. per min. is due to splitting the air current, the power producing the circulation remaining unchanged. In this case, the power being constant, and the quantity being doubled, the pressure produced by the circulation is one-half of the original pressure; because when the power remains unchanged the pressure varies inversely as the quantity of air in circulation. Therefore, assuming the circulation is doubled by splitting the air current, the water gage required to circulate 40,000 cu.ft. of air per minute would be ½ in. instead of 4 in., as in the previous case.

To make the question complete, it should have stated, "the power remaining unchanged"; or else have mentioned the cause of the increase in circulation.

QUES.—What power is required to lift 15 tons with three screw jacks with ½-in. pitch, one lever to each jack 4 ft. long?

Since the use of the word *power* always implies the element of time and no time is mentioned in this case, the question cannot be answered as it stands. It must be assumed that the question intends to ask, What *force* must be exerted at the end of a 4-ft. lever, to raise a weight of $15 \div 3 = 5$ tons, with a screw jack having a ½-in. pitch.

No data being given by which the frictional resistance of the screw can be calculated, it is possible, only, to calculate the theoretical force required to lift the given weight. This is found by equating the inch-pounds of work performed in lifting a weight of 5 tons through a vertical height of ½ in., with the work performed by a force x exerted through the circumference of a circle whose radius is 4 ft., or 48 in. The circumference of this circle is $2\pi r = 2 \times 3.1416 \times 48 = 150.8$ in., nearly. Then,

$$150.8\,x = 5 \times 2000 \times ½ = 5000$$

$$x = \frac{5000}{150.8} = 33.15 \textit{ lb.}$$

[Attention is not drawn to these questions in the spirit of idle or aimless criticism; or for the purpose of holding up to ridicule the honest efforts of our mine-examining boards, the members of which, for the most part, work under difficulties that can be appreciated only by those who have served in similar capacities; but rather to emphasize the need of more study and care in the preparation of questions to be submitted to candidates in examination. —ED.]

Coal and Coke News

Washington, D. C.

The action of the Senate on Oct. 10, in sending back to the conference committee for further consideration the Alaska coal land leasing bill creates, in the opinion of not a few persons, a situation that will prevent final action on the coal bill at this session, particularly if adjournment is taken within a week or ten days, as it is now hoped by many will be the case.

The Alaska coal bill has proved to be a serious bone of contention ever since the conferees began their attempt to harmonize the House and Senate drafts, and the conference with the subsequent debate has proved to be a renewal of the old Alaska conservation of coal lands squabble that raged so violently during the Ballinger-Pinchot controversy some years ago. The criticism upon the final work of the conferees is based upon what is considered to be the limitation of government power over the coal lands, and was voiced by Senator Lane in remarks on the conference report, as follows:

The Secretary of the Interior is forbidden from having anything to do either with the operation of the mines or the working of them. . . . The lessee can operate his mines under the most onerous conditions . . . relating to the employment of labor. He can bring about a condition which is identical with that which has existed in other coal-mining districts in this country, of which we have heard so much of evil in the recent past. He can have gun men on his lands; he can do anything which he pleases with his employees. He can fail to ventilate the mine; he can operate it under conditions which are absolutely dangerous, for the reason that this clause, in my opinion, controls every other provision in the bill preceding it. It is the keystone which will control the operation of those mines under this law.

I would like to have the Senate know exactly what they are doing, or at least what I think they are doing, if they pass this provision. The lessee can hold his coal for the highest price; he can keep it out of the market; he can sell it to the warships of a power at war with this country if he wants to do so.

The government agent is forbidden to have a word to say about it, and when you forbid him, you forbid this nation. There is not only a bar forever upon the government taking proceedings against the lessee, if it does not act in 90 days after it gives notice, but there is also a bar upon the government from doing anything else. Unless it was carefully designed for the purpose of compelling the government and the people of this country to keep their hands off and to allow the private owner to run the mine in any manner he wants to run it, I do not see why it was put in. It has that effect.

If I were the lessee of a coal mine in Alaska and wanted to operate it at my own sweet will and make the most out of it, gut it and rob the labor and do anything else I wanted to, without interference or supervision, I would like to have this provision remain in the bill. If, on the other hand, I was representing the government and wanted the mine operated properly and the products from it handled in a manner which would be beneficial to the community and to the people at large as well, and at the same time do justice to the owner thereof, it is the identical kind of a provision that I would keep out of the bill if I could. Here is the government tied to leases of its own land under a law which forbids it from taking any action for the relief of conditions which may be against the interests of the people of this country. It compels the government to give 90 days' notice, but if it does not go into court within 90 days and make good, the government and the people are forever debarred from further action. On the other hand, the lessee of the mine has unlimited time granted him. The short end of the rope is given to the government and the people of this country who own the land, and one of whose resources it is.

Under another section of the bill, any man may take up as much as 5000 acres under a lease. The Senator from Nevada (Mr. Pittman) informed us a few days ago, when the bill was before the Senate, that in one of those fields, I think it was the Matanuska, there are not over 15,000 acres of good coal land. Two lessees could go out under this act, under another provision, however, and secure all the land except what is reserved by the government. You may depend upon it, the government will not get the best of the coal land. If anyone thinks the government is going to get the best of the coal lands when it comes to locating it, I think he will find he is mistaken. That land is pretty well known now. It has been prospected and looked over with careful eyes by experts, and the best of it will be leased. They are allowed to take as much as 5000 acres, and two or three men can cover, we will say, a field of 10,000 acres and control the coal situation in Alaska.

These leases will not be for the benefit of the people of Alaska if this provision is left in the bill. They must depend on the Secretary of the Interior as the agent of this government, and he is not allowed to have anything to do with it or to say about it. You give him 90 days if he wants to file a notice in which to begin a court proceeding. I have seen a notice improperly written where a man rode one day and night in order to "stake" it on a claim, and for the reason that he did not have it properly worded he lost his claim. It is very easy to make a mistake in a notice. Many good attorneys do not know how to write them properly. Anyone who has had experience in a mining country knows that. The government is forever barred from rectifying any mistake which its agents may make forever and ever, whereas the person who owns the lease has time without end in his favor to hold and operate it under conditions which the Secretary of the Interior and the government of the United States are forbidden to question or even ascertain. He is forbidden to interfere in any way. If he goes around to look into the conditions, that is interference. If he takes the time of the employees to ride him up and down the shaft or enters a drift to examine the mine, he is in the way, and he is interfering with the operation of the mine, and they can oust him under this clause.

Possibilities of South American Market

An increasing interest is expressed in government circles with respect to the possibilities of the sale of American coal in the South American market. The following statement, which has been prepared by a private concern, gives the facts in a way that is believed by government authorities who have been making a study of the situation to be correct:

It is not now seen definitely what form the enterprise of our coal companies in developing the South American market will take. Some of them have become actively interetsed. Will they wait for demand, and fill orders, or will they go down and establish distribution? At the present, excepting for one or two important exhibitions of enterprise, the coal interests seem to be waiting for orders.

Ultimately, it should be possible to sell coal from the United States in Brazil or in Argentina cheaper than to sell Cardiff coal there. Good quality fuel, such as is purchased by South America, has recently sold at about $3 per ton f.o.b. both at New York and at Cardiff. The cost of shipping to Rio de Janeiro has been $3.65 per ton from our Atlantic ports. Cardiff has in the past had an advantage in rates because ships sent down there are always able to get return cargoes, but the differences are becoming less and less. There are port costs at Rio aggregating $1.24 per ton, including "dispatching," customs, statistical charges and lierage. Altogether, "soft" coal has cost about $8 a ton at Rio. The shipping costs are much the same to Buenos Aires, the advantage of better return cargoes offsetting the difference in distances.

Argentine railways figure the cost of their locomotive coals on the tenders at $10 per ton. The most important adverse element in the economies of coal shipment to South America under present conditions is, however, the lack of dockage facilities for coal from the United States in the South American ports. A few weeks ago it was estimated that the costs of a speculative shipment of 10,000 tons of coal to Buenos Aires would be $85,000 in round figures, with insurance and freight upon a chartered vessel counted in, and unless arrangements had been made for discharging the cargo within a limited number of days after arrival, an additional cost at the rate of $600 a day would have to be counted upon.

All South American coal docks are owned either by European interests, by the steamship companies or by a single concern with European business affiliations in almost every port. All this explains why coal merchants in the United States are not sending off coal to sell for what it will bring in South America.

To make profitable on a continuing basis the sale of our coal in South America's east coast cities, it will be necessary for the business to be permanently organized. Coal docks ought to be purchased, mechanical unloading devices should be installed and special ships should be chartered. The latter is not so very important, as ordinary ships may be unloaded mechanically without enough loss of time to count considerably.

Certain of our coal companies are studying the situation with some such permanent organization in view. But the movement of coal southward now is apparently on direct order.

In the coal trade, it is said that Chile is making inquiries and will next month probably ask for bids for 300,000 tons of coal per year for three years. The Argentine Navy is also said to be inquiring. It is explained that the South American demand has already affected the domestic market for coal, and that quotations on a contingent basis extending over the first of next year have been refused because of the probability of a rise in the price.

HARRISBURG, PENN.

The anthracite coal regions are suffering from the exceptionally severe drought. There has been but one rain since the last week in August, and that was hardly sufficient to moisten the ground. Prior to Aug. 30, a dry spell prevailed, so that there has practically been a period of water famine for 11 weeks, unprecedented for this time of the year.

The drought has added to the operating expenses of many of the coal companies, some of which have been obliged to put special water-hauling trains in service. Others have been forced to extend mains and get their supply from new sources, farther away from the mines.

Despite the drought the output of the collieries has not been reduced. Last month, the output was 370,000 tons more than in any September in the anthracite industry. The total production was 6,256,192 tons, an increase of 673,913 tons over the same month last year. The September output exceeded even that of September 1912, which heretofore held the record with 5,876,496 tons.

The effects of the drought are felt more in the Schuylkill region than through the Lackawanna, Wyoming and Lehigh regions, where the big companies, profiting by previous experiences, have in recent years been carefully conserving their watersheds and sinking artesian wells, which seem to afford a sure relief against the periodical dry spells that hit this part of the country.

The Lehigh field has been the least affected, principally because the Lehigh Valley Coal Co., the chief producer here, years ago bought up the water rights in and around Hazleton, and thus has an abundant supply under the most unfavorable conditions. The company is making further provisions against drought by the construction of large reservoirs at Drecks Run, at the mouth of Never Failing Springs four miles from Hazleton, where the water trains run from the Schuylkill region to fill their tanks. But for this supply some of the mines would have to close down.

Through the Schuylkill region, however, the worst drought in 50 years is being experienced. All the feed streams to the reservoirs and the springs have long since dried up, and the region is depending at the present time solely on what water is stored and on tank trains. For drinking and domestic use the people are in some cases carrying water for miles.

The Philadelphia & Reading Coal & Iron Co. has adopted drastic measures to secure a sufficient water supply to keep up steam in the boilers. Should the trains, which are now being run carrying water to places where it is most needed, fail of their purpose, it will mean a colliery suspension. At Lakeside, East Mahanoy Junction, there is a large quantity of water stored and this is now being drawn upon by the Reading company. South of Broad Mountain, the Reading is also drawing on the Tumbling Run Dams, several miles from Pottsville.

While the stored water at points referred to holds out every effort will be made to keep the collieries working when there is the heaviest demand for coal. Aside from the water supply, which the Reading company owns, it pays considerable sums in royalties for the daily supply for several large trains.

The drought which has fallen on the western part of the state bids fair to result in the stoppage of work in several of the largest mines in the bituminous region, unless relief is soon had. Some of the largest mines in Westmoreland, Washington, Greene, Somerset, Cambria and Allegheny counties have been forced to close down within the last week or 10 days, because water for the boilers could not be obtained in sufficient quantities to operate them. Cokeburg, mines are idle owing to the drought, and Ellsworth is only running part of the time. Pigeon creek is practically dry in many places.

PENNSYLVANIA

Anthracite

Throop—The 1200 men employed at the Price-Pancoast Colliery, who were made idle some time ago on account of caving in various chambers of the mine, have resumed work, the places having been put in safe condition for operation.

Nesquehoning—Claiming that the Lehigh Coal & Navigation Co. had discriminated against four company miners when it discharged them, the 500 employees of the No. 11 colliery went out on strike on Oct. 9, throwing the colliery idle. The company insists that the men were discharged for quiting work before the regular time.

Shamokin—Oliver Eishehauser, assistant foreman at the Susquehanna Coal Co.'s Hickory Ridge Colliery, was walking across a breast on Oct. 10 when he stepped into a body of gas which rushed from an adjoining chamber. He was hurled to the bottom of the gangway and was fatally injured.

Deringer—Lehigh Valley coal and railroad company detectives in the Hazleton region, believe that another attempt was made on Oct. 10, to wreck the pay train of the Lehigh Valley Coal Co When the pay train was returning from Deringer to Hazleton, the engineer thought he saw an obstruction on the track ahead, stopped the train and started to make an investigation. He found several sticks of dynamite along the track and also discovered that one had been exploded with a fuse. The work was evidently that of a person not well acquainted with the use of dynamite.

Bituminous

Pittsburgh—The Pittsburgh Foreign Trade Commission on Oct. 10 received a request from the Government of British Guiana asking that some concern in a position to ship 5000 tons of bituminous coal per month for the next 12 months communicate with them immediately. Accompanying the request was the price the British Guiana Government officials are willing to pay for coal, with a bonus offered for prompt delivery. As the figure named is something in excess of what coal is bringing here, the order will probably be divided between two or three local concerns who are in a position to make prompt shipments.

Connellsville—The Connellsville coke business showed slight gains recently in production and shipment, but the total is still in the neighborhood of 250,000 tons per week. The furnace production receded, but merchant output increased. The drouth is a serious problem to many of the coke makers.

Mount Pleasant—The University of Pittsburgh through its new extension plan, proposes establishing a mining class at this place for the benefit of the community. The work will include advanced studies in mining, including preparation for fire boss, assistant mine foremen and mine foremen's examinations next spring. No charge will be made for the instructions except the expenses of the instructor.

Huntingdon—On Oct. 8, a boiler in the power plant of the Rockhill Coal & Iron Co., exploded, killing one man and severely injuring two others. The company's damage was $6000. The coal tipple was demolished and two other boilers injured. About 280 employees will be thrown out of work for at least a month. The cable on the incline at the McIntyre mine, Finleyville, broke the same day and two cars dropped down and crashed through the tipple to the railway tracks below. Three men were badly injured.

Charleroi—A total of 14,739,000 bushels of coal passed down the Monongahela from river mines during the month of September. This is considered a satisfactory showing in view of the fact that low water conditions in the Ohio river prevented shipments of coal to the south and that barges for loading were in limited supply at many of the river mines. In September, 1913, when conditions were more favorable, 17,699,000 bushels were shipped down the river and in August of this year, the shipments aggregated 12,648,000 bushels.

WEST VIRGINIA

Charleston—An agreement was recently reached between the Branch Coal Co., operating at Elverton, on New River, the special board of arbitration and Governor H. D. Hatfield, the referee, whereby the miners who have been on strike there since July 1, resumed work. The company, it is said, has agreed to reinstate all of its former employees, about 100 men being employed at Elverton.

Fayetteville—The sale of the large timber holdings of the Sewell Lumber Co. to the Babcock Coal & Coke Co. has been confirmed by the circuit court, the price of $230,000 being satisfactory to the creditors of the selling company. The management which has been operating the property will be retained. The property consists of approximately 10,500,000 feet of standing timber, 4,700,000 feet in logs and $100,500 worth of manufactured lumber. Mr. Babcock held a vendor's lien on the property for $50,000, and paid $180,000 in cash for it, representing the difference between the agreed price and the amount of his lien.

Macdonald—In reply to inquiries received from Charleston, Huntington and other cities which desired the company to locate there, the New River Coal Co. recently announced that it will not at present move its general offices from Macdonald, on account of the unsettled conditions existing. It is probable, however, that the contemplated move will be made as soon as conditions become more nearly normal.

KENTUCKY

Sebree—A. B. Cobb and C. M. Melton are making preparations to develop coal lands in this vicinity.

Louisville—Complaints of the Stonega Coal & Coke Co. and the Blackmore Coal & Coke Co., both with mines near Big Stone Gap. Va., against the Louisville & Nashville R.R. Co., were heard here by representatives of the Interstate Commerce Commission recently. By this action the mining companies seek to compel the Louisville & Nashville to publish through interstate rates from the complainants' mines to various points touched by the road. At present, it is set forth, the complainants are compelled to pay 10 cents extra in order to get the products of their mines to Appalachia Junction, from which point they pay regular interstate rates. The Commission's ruling is not expected for some time.

Pikeville—With general business conditions in their present state, there is little in the way of new operations in prospect in eastern Kentucky. Money is scarce and the coal market is not now in a position to encourage new ventures.

Two new operations, however, are being opened near here. One is located on the John Roberts property at Penny, on Shelby Creek, and is backed by J. G. Pierce and other Ashland capitalists, while the other, nearby, is promoted by George W. Gray, of Paintsville. Both of these operations are within the bounds of the Elkhorn coal field in Pike county.

OHIO

Athens—The rumor persists in coal circles that the Lorain Coal and Dock Co. will reopen its old Eclipse mine, located midway between Athens and Nelsonville in the Hocking Valley. It is said one of the large mines of the company in eastern Ohio will be dismantled and the equipment moved to the Eclipse mine. The officials are not yet ready to make a statement but the move is being considered.

St. Clairsville—The union miners' supply store at Provident near here, was destroyed by fire on Oct. 6, with a loss of $9000, the fire being the second in the building in the past few months. Local officers are investigating a report that the fire was of incendiary origin.

Bellaire—International Secretary-Treasurer William Green and State President John Moore, of the Mine Workers, have arrived in the eastern Ohio fields for the purpose of taking up the work of relieving the distress existing among the families of the 16,000 striking miners.

INDIANA

Petersburg—The S. W. Little coal mines, 7 miles south of here, at Little, employing 400 men, have closed down for a month, during which they will be overhauled and placed in condition for the winter run.

Sullivan—W. D. Hunter, of Terre Haute, has leased the Reliance mine near here and expects to have 150 men at work by the first of the year. A bonus of $1000 was raised for him by business men. The mine had been closed for months.

Indianapolis—The executive officers of the U. M. W. of A. announce that beginning with Dec. 1 the "Journal" will change from a weekly in its present form of 8 pages to magazine form of 32 pages and will be printed in English, Italian and Slavish, the three languages that it has been decided will reach the largest number of the organization's members.

ILLINOIS

Herrin—The railroads in southern Illinois are refusing to give cars to the mines on account of the unusually large number of unbilled cars on the track. One mine had 184 "no bills," which consisted of screenings and the washed sizes from No. 2 down. Many mines in this section have from 25 to 50 thousand tons of screenings dumped on the ground.

MISSOURI

Rich Hill—The Perry-Page-McMahan-Holland Coal Co., which is said to have a large area of coal land in the Carbon Center district, is alleged to have been conducting operations successfully for a month past with strip pit machinery. The coal bed, 4 to 6 ft. thick, lies 30 ft. below the surface, where the stripping equipment is now operating, two miles south of Carbon Center.

ARKANSAS

Fort Smith—A 14-ft. bed of coal of excellent quality, 50 ft. below the surface, is reported to have been discovered by Stewart N. Kenney, a coal expert, while drilling on the Campbell farm near Van Buren. Eastern operators are said to have sent men to investigate. The discovery was reported early in October.

KANSAS

Pittsburg—A district convention of mine workers on Oct. 6 arranged to support a suit for damages against those who brought charges of graft against Alexander Howat, former president of District 14.

PERSONALS

A. L. Bogt, formerly connected with the Chapman Mining Co., of Columbus, has accepted a position with the Colonial Coal & Supply Co., of Columbus.

Harry M. Taylor, of Chicago, has recently associated himself with the Central Coal & Coke Co., of Kansas City, Mo., in the capacity of vice-president.

H. Ward, Jr., with office at 619 Ferguson Building, Pittsburgh, Penn., was recently appointed a special representative in the Pittsburgh region of the Scranton Pump Co. of Scranton, Penn.

J. W. Johnson, superintendent of the Lorain Coal & Dock Co.'s mines, has received word from headquarters to ship all mine mules to Columbus for the winter. These animals will be loaded at once.

Willis E. Holloway, Pittsburgh representative of the Roberts & Schaefer Co., of Chicago, will, on and after Oct. 15, have his headquarters at the home office, namely the McCormick Building, Chicago, Ill.

C. M. Anderson, formerly of the C. M. Anderson Coal Co., Columbus, Ohio, has been appointed Western sales manager of the Elk River Coal & Lumber Co., of Clay, W. Va., and has opened up offices on the eighth floor of the Columbus Savings & Trust Building.

Charles J. Finger, general manager of the Ohio River & Columbus R.R. has been named receiver for the property by the local courts. Judson Harmon representing the stockholders applied for the receivership. The road operates between Ripley and Sardinia and connects with the Norfolk & Western.

C. M. Moderwell, of Chicago, was recently elected president of the Illinois Coal Operators Associations. F. C. Hammold was chosen secretary and treasurer, James Neeham was elected vice-president, and Edwin G. Bend was elected as the operator member of the arbitration board to settle disputes with the Miners' Union.

OBITUARY

John Forrester, president of the Forrester Coal & Coke Co., and owner of the Paradise mine, died suddenly at his home in Duquoin, Ill., on Oct. 8. Mr. Forrester was one of the best known mining men in southern Illinois, having held many important positions in connection with mining affairs in that section.

Edmund C. Donk, president of the Donk Bros. Coal & Coke Co., age 63 years, died at his home in St. Louis, 3643 Castleman Ave., on Oct. 9, after a long illness. He was born in Germany on Feb. 19, 1851, and came to this country at the age of 5, living first in Peoria, Ill., and coming to St. Louis at the age of 12 years. He engaged in business with his brother, the late August Donk. He was also president of the Merchants & Manufacturers Investment Co., vice-president of the St. Louis, Troy & Eastern R.R., and vice-president of the East St. Louis, Columbia & Waterloo R.R.

TRADE CATALOGS

The Cross Engineering Co., Carbondale, Penn. "Perforated Metal, Coal Preparing Machinery and Simplex Rivetless Chains." Forty-five pages, 6x9 in., illustrating and describing various coal screen perforations and conveyor chains.

CONSTRUCTION NEWS

Jellico, Tenn.—A company has been formed to build a railroad from this city to Capachine Creek for the purpose of opening up the coal and timber fields lying to the west of Jellico. It is believed that this will greatly add to the prosperity of both Jellico, Tenn., and Jellico, Ky.

Gallitzin, Penn.—The tipple at No. 10 mine of the Pennsylvania Coal & Coke Corporation which was recently damaged by fire, is being rebuilt. It is believed that the improvement will be completed in a short time. The operation of the mine meanwhile, is still going on.

Whitesburg, Ky.—The Kentucky-Dean Coal Co., recently organized at Viper in the Perry County coal field, is starting a coal development there, employing a considerable force of men. It expects to begin shipping coal within 90 days, it is said. The new operation is on the main line of the Lexington & Eastern R.R.

Morgantown, W. Va.—D. M. Chaplin & Co. recently closed a contract with the Monongahela Coal Co. for the building of a tipple at the coal company's mine. This contract includes the installation of all necessary machinery and the work will be undertaken at once. The plans call for a gravity chute, which is considered an improvement over the type of tipple formerly used in this section.

Blackfield, Penn.—Twenty-five more houses to accommodate the miners families of Atlantic No. 2 mine are to be erected for the miners' who wish to remove to the scene of their work. Twenty-five miners' homes have already been

built but the company found that these will be insufficient. The settlement has been christened Blackfield, in honor of Black Brothers who control the operation.

Clay City, Ky.—The Day Bros. Lumber & Coal Co. is beginning the construction of a branch line of railroad up King's Creek to reach rich coal and timber holdings. The line will be about five miles long. It is the purpose of the company to develop the rich cannel coal fields, and forests, the development work to start at once. Several hundred men will be given employment in the new development, which will be among the largest in Eastern Kentucky. The grade work is billed to be completed by Feb. 1 and by Mar. 1 the coal operations will be well under way.

Fayetteville, W. Va.—The Boone County Coal Corporation is opening up an extensive operation on Beech Creek, in Boone County, and expects to be taking out coal within two months. The construction of a railroad to connect the location with the Coal River branch of the Chesapeake & Ohio R.R. has been under way for several weeks, and is expected to be finished soon, giving the property the necessary rail outlet. The mine will produce No. 2 gas coal. The company has leased 800 acres of coal land on Beech Creek to the Michigan & West Virginia Coal Co., organized by Detroit interests, and the lessee is preparing to begin development work.

NEW INCORPORATIONS

Cleveland, Ohio—The Pluto Coal Co. has been organized for the purpose of mining with a capital of $10,000. The incorporators are M. A. Copeland, J. A. Eldon, H. H. Mosel, C. Verbesky, and M. Barge.

Penny, Ky.—The Penny Coal Co. has increased its capital stock from $50,000 to $75,000 and will make some increases in its coal mining plant on Shelby Creek, said increases to be complete by the first of the new year.

Jeff, Ky.—The Hamden Coal Co. has been organized here to make a large coal development. The incorporators are: W. H. Hall, J. M. Combs, Felix Combs and others. They propose starting the work of development by Jan. 1.

Viper, Ky.—The Viper Coal & Development Co. is being organized at Viper, to make a coal development, the work having already started. A large force of men are already at work opening mines, building miners houses, etc. The development is on the L. & E. main line.

Charleston, W. Va.—A charter has been issued to the Taylor Collieries Co., the incorporators of which are William A. Taylor, James M. Taylor, Charles P. Taylor, and Newton F. Hawkins, all of Pittsburgh. The company is capitalized at $100,000, and will have offices in Charleston. Coal mines will be worked in Harrison Township.

INDUSTRIAL NEWS

DeKovan, Ky.—The Ohio Valley Coal Co.'s tipple and the Illinois Central freight house were destroyed by fire a few days ago; the loss is not stated.

Middlesboro, Ky.—It is understood here that the Southern Ry. has placed a large contract order for coal with the mines on Stony Fork and in Wingo Hollow. This is counted on to keep the mines in this section busy for a time at least.

Knoxville, Tenn.—A conference of coal operators and officers of the United Mine Workers of America will be held at Soddy, Oct. 28, for the purpose of arranging certain matters relative to the miners' wage scale.

Washington, D. C.—An advance of 10c. per ton in the freight rates on coal purposed by the Southern railroads was recently filed with the Interstate Commerce Commission. Unless suspended by the commission the increase will become effective Dec. 1.

Charleston, W. Va.—The "Lucy Marmet," one of the largest towboats on the Kanawha River, was totally destroyed by fire recently, with a loss of about $20,000. The boat was owned by the Marmet Coal Co., and had been in commission about 11 years. It is not known how the fire started.

Philadelphia, Penn.—All records for coal handling at this port were recently broken when 5500 tons of cargo and bunker coal were dumped into the hold of the steamer. "Castle Bruce," in four hours and 30 minutes. Some years ago 4100 tons of coal were loaded into a vessel at this port in 14 hours. This was considered a remarkable feat. The present record was made possible by suitable coal handling machinery.

Buffalo, N. Y.—There is a possibility of saving the Buffalo & Susquehanna Ry. the coal and lumber line built from Buffalo to Wellsville by the Goodyear interests. The Pennsylvania R.R. is making a survey of the road and may lease it, in which case the order of discontinuation, effective on Nov. 1, will be recalled.

Louisville, Ky.—The St. Bernard Mining Co., through Julius Bierach, of the Louisville office, has closed a contract with the Kosmos Portland Cement Co. to run for five years. This contract calls for a total of 180,000 tons of coal. It will be delivered via the Illinois Central on which both the plant and the mines are located.

Ensley, Ala.—All operations at the Tennessee Coal, Iron & Railroad Co.'s properties in Ensley will be resumed shortly. While the past partial shut-down has not caused any great discouragement in this district, at the same time it will be extremely gratifying to know that the plant will be running to full capacity soon.

Washington, D. C.—West Virginia coal operators represented by the Hitchman Coal & Coke Co., will ask the Supreme Court to review the action of the Fourth United States Circuit Court of Appeals in reversing the decision of Judge Dayton to the effect that the United Mine Workers was an unlawful organization. This case has attracted widespread attention from both capital and labor.

Olympia, Wash.—The Thurston County Superior Court has issued an order suspending the recent order of the Public Service Commission for lower freight rates on coal from Roslyn to all parts of the state, and required the Northern Pacific R.R. to furnish a $25,000 bond to protect shippers and customers pending the final decision of the court.

Birmingham, Ala.—The Pratt Consolidated Coal Co. recently resumed work on the mine openings and coal barges of the Warrior River to take care of the river navigation. This company was engaged in constructing barges for transporting coal to the Gulf Ports and opening a mine for securing the fuel when the government hesitated about finishing a lock which was necessary for the success of the enterprise on the Warrior River. The government has promised to construct the lock and finish it at once; hence, the resumption of work.

Newark, Ohio—One of the most important happenings in coal mine circles in Ohio during the past week was the announcement by the Newark Natural Gas & Fuel Co. to the effect that after Nov. 30 the distribution and sale of natural gas will be discontinued. This action was taken because of a conflict over the franchise and the price to be charged for the gas. This announcement means a large market for coal and already many of the householders have laid in a supply of fuel. Manufacturing plants and business houses are also affected.

Toronto, Ont.—The Mountain Park Coal Co., the capital of which is mainly British, and which has holdings of about 6000 acres on the head waters of the McLeod River, about 200 miles southwest of Edmonton, Alta., is making preparations for a large output during the winter. It has its own railway 31 miles in length, connecting it with a branch of the Grand Trunk Pacific. The present output is 500 tons per day, but the mines are being developed to a capacity of 2500 tons per day. The coal is high grade bituminous, suitable for steam and domestic purposes.

Pittsburgh, Penn.—Permission to foreclose on a mortgage of $6,309,500, on which there is interest due of $315,475, was asked in a bill in equity recently filed in the Common Pleas Court by the Commonwealth Trust Co., Trustee against the United Coal Co., and James D. O'Neil, Robert T. Watt and William E. Johnson, receivers of the coal company by Attorneys, Watson & Freeman, and Sullivan & Cromwell. The plaintiff asked for permission to sell at public sale the coal lands of the United Coal Co., together with those of other coal companies pledged with the trustees as security on the mortgages.

Cincinnati, Ohio—It is reported that the Chesapeake & Ohio loaded in the Kentucky and West Virginia fields during the month of September, 2,110,735 tons of coal, which is an increase of 334,515 tons as compared with the same month of last year, and a decrease of 105,725 tons loaded in the previous month, August, which was the best month in the history of the road. There were two more working days in August, however, which partly accounts for the difference. This road has issued a note to operators along its lines requesting that all shipments destined to the Lakes be discontinued, as far as possible, by Oct. 15, in order to get all such shipments out of the way in anticipation of the looked-for commercial revival.

Coal Trade Reviews

General Review

Anthracite steady, but lacking the customary snap at this time. Bituminous continues to drag and the export business is scarcely above normal. All markets are much dependent on colder weather. Lake shipping is somewhat better.

The relatively high temperatures prevailing over the past few weeks have caused a slowing up in the demand for hard coal, and the trade is essentially marking time, pending the appearance of colder weather. Market observers, however, are agreed that this is but a temporary condition, and that the trade will respond quickly to a return of more seasonable weather; in fact, there are reports in some sections that the companies are even now falling behind in their shipments, so that there is some anxiety as to what the situation will be when the fall rush opens up. The demand still centers on stove coal, which commands a premium when sold by itself. Egg coal and the steam sizes are inclined to drag.

The bituminous situation at Tidewater is still generally irregular, and even more discouraging. The resumption of shipping from the Welsh ports, the difficulty American operators found in arranging satisfactory terms with prospective purchasers in the foreign countries, in addition to the tight money market and the danger of violating neutrality laws, have all been restraining influences, adverse to a more general expansion of our export business. There has as yet been no significant change in quotations, but the offshore business has materially contracted for the time being at least, and there are excessive accumulations at most of the ports. About the only constructive feature of the current situation has been some slight improvement in the bunkering demand.

There have been no developments of a favorable character in the Pittsburgh district; in fact, the operators are now looking forward to another severe slump when Lake shipping closes. The constantly recurring reports of large orders from abroad for American goods may create an expansion in general manufacturing which will do much to relieve the situation, but, as a rule, there is not much hope of an active market before the first of the year at least. The domestic market in Ohio is dull and hinging on the weather conditions. There has been some spurt in the Lake trade, while the circulars are generally well maintained, and it is expected that the domestic trade will right itself promptly when the weather becomes more seasonable.

In the Southern market, the domestic trade, which has been the only encouraging feature of the situation there, has slowed up materially under the influence of adverse weather conditions, and operations are now curtailed to fully half capacity; the general belief that any change from now on must be for the better is the only hopeful feature at the moment.

The steam market in the Middle West is still weak, while the recent strength in the domestic trade is now confined more particularly to certain restricted sizes, the others being much easier. The market has been overshipped on some grades, on which a definite recession in the demand is noted, with occasional accumulations on demurrage. No general improvement is anticipated before the first of the new year.

ATLANTIC SEABOARD

BOSTON

Hampton Roads coals quiet. Tendency of export trade is to sag, and coastwise shipments are confined to contract application. Georges Creek about normal and uneven market for Pennsylvania grades continues. Anthracite shippers falling behind on deliveries.

Bituminous—The Pocahontas and New River market is practically featureless. The amount dumped at the piers has been only fair and the volume standing in the terminal yards is still much heavier than normal. Off-shore demand is still irregular with a general tendency to sag partly because of the resumption of normal loading at the Welsh ports. Satisfactory terms of settlement continue to be difficult to arrange and together with the tight money market and the possibility of colliding with the rules of neutrality, most inquiries are subjected to close scrutiny before commitments are made.

In this territory about all of the receipts are being applied to contract business. A spot market does not exist, except for small tonnages up the line from the various distributing points. Prices show no significant change, however, and it is felt that present values will probably hold until the industrial situation shows a change for the better; $2.85 f.o.b. Hampton Roads is the prevailing quotation although it is well recognized that the buyer of spot coal can negotiate for less.

The market for the Pennsylvania grades seems rather uneven. For some coals there is a fairly steady call but for others the situation is so stagnant that several operations have been shut down for the time being. The only really active feature now is the moderate rush to get forward sufficient supplies for points like Bangor where navigation normally closes the latter part of November.

Water Freights are still at the season's minimum. There is a dearth of inquiry and rates are nominal at 65c., Hampton Roads to Boston, on fair sized vessels. Steamers are a drug on the market.

Anthracite—In some quarters the policy of suspending mining operations during the summer dullness is now beginning to show its effect. Practically every order requires a proportion of stove size and several of the shippers are able to supply it only after considerable delay. If this is an indication of the state of things now there will surely be an active market later when the cold weather appears. Dealers who were relying on regular shipments week by week find that the companies are getting behind on their orders.

Bituminous prices at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.90@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.15@2.80	2.50@2.90	2.92@3.02	
New York*	2.40@3.10	2.80@3.20	3.22@3.32	
Baltimore*	.....	.....	2.85@2.95	
Hampton Roads*	.....	.....	.....	$2.80@2.85
Boston†	.....	.....	.....	3.60@3.78
Providence†	.....	.....	.....	3.63@3.73

* F.o.b. †On cars.

NEW YORK

Spot bituminous market practically dead but contract movement continues fair and there is little coal reported on demurrage. Prices are low but steady. Heavy call for anthracite stove coal continues unabated. Steam sizes still relatively weak but improving.

Bituminous—Although there is almost a complete absence of demand for spot bituminous the market continues in a healthy condition. The lack of demurrage coal is particularly noticeable. It is seldom that the higher grades are forced on to demurrage there being almost at all times a ready market for them, but the cheap fuels, that only move satisfactorily under abnormal conditions, often cause trouble in

this respect. The coal is produced cheaply, very frequently without regard to preparation, and ordinarily sells at a low price but when on demurrage it is sacrificed at rediculous figures. This has a tendency to fix a price which is not always indicative of the market conditions as a whole. Nevertheless it has an effect tending toward demoralization which is to the advantage of neither the producer nor the consumer.

The contract coal moves along in fair shape. While some plants are closed entirely and others are only taking 25 to 50%, a fair average would probably be 75 to 85% of normal; in some few instances where the war has increased the demand for particular lines, factories are working overtime and consequently taking an additional supply. The export business has fallen off to about normal.

While there is no prospect of car shortage or other reasons for inflation of prices the outlook, with winter now approaching, is good and business on its present basis should be maintained. The market is not quotably changed from last week which we continue as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.55@2.65; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

Anthracite—In spite of the exceptionally warm and unseasonable weather all of the anthracite prepared sizes have been moving well with the exception of egg. Stove still continues short and is selling in some quarters at a premium when moved alone.

The moment that one size begins to be a trifle short there seems to be a desire on the part of all of the trade to get shipments on this particular size; the tendency is towards placing of larger orders than necessary to cover requirements. This same condition obtained last year at this same season and reached a point where stove was almost unobtainable, when suddenly within a very few days the bottom dropped out of the market. There is a question whether this same condition will not apply this year.

It is a fact, however, that notwithstanding the tendency on the part of the operators to cut down the percentage of egg produced, the market on this size has continually become weaker from year to year. The consumer has been steadily changing from egg to stove, having found that more economical results could be had from the stove size.

Steam sizes are not active, but cold weather would also improve the condition on these sizes, especially on pea which is used extensively by the large apartment buildings throughout New York City. The demand from the West and all-rail into New England and Canada is very brisk and as soon as egg begins to move the situation on all sizes should be most satisfactory.

The New York hard coal market is now quotable on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.10	$4.60@5.10	$5.05	$4.45@5.05
Egg	5.35	5.10@5.35	5.30	4.95@5.30
Stove	5.35	5.35@5.45	5.30	5.30@5.40
Chestnut	5.60	5.45@5.60	5.55	5.40@5.55
Pea	3.55	3.40@3.55	3.50	3.35@3.50
Buckwheat	2.80	2.65@2.80	2.50@2.75	2.25@2.75
Rice	2.30	2.00@2.30	2.00@2.25	1.50@2.25
Barley	1.80	1.65@1.80	1.75	1.50@1.70

HAMPTON ROADS

Export shipments are slowing up. Prices still at circular. Some small shipments of nut and slack moving coastwise.

Dumpings at Tidewater ports during the week have not been heavy and there appears to have been a decided falling off in demand, both in the foreign and domestic markets. The greater part of the coal moving coastwise, so far as can be learned, seems to have been on contract although some spot sales have been made. The movement foreign has been almost at a standstill during the entire week, few cargoes having been cleared. As is usually the case the largest coastwise cargoes have gone to Boston. In addition to Pocahontas and New River mine-run there has also been some movement of nut and slack and high volatile.

Prices so far as can be ascertained have been around $2.80 to $2.85 for mine-run and about $2.60 for the other grades. There seems to be some little increase in the number of vessels calling for bunker coal but the quantity going out is still below normal.

The accumulation of coal here is somewhat in excess of usual. This is due to some extent to vessels which were expected not arriving on time and it will, no doubt reduce to a large extent during the next few days.

PHILADELPHIA

Slight easing off in demand for anthracite, owing to unseasonable weather, but mining continues in full swing. Bituminous still fails to show improvement. All seem to have ample stocks.

Anthracite—The weather thus far has been anything but conducive to the sale of anthracite coal, but notwithtsanding this condition, there is considerable coal moving, and were it not for the fact that the operators are hampered with small sizes, the situation would be entirely satisfactory. It will take cold weather, however, to put the customary snap into the market.

The production this week was somewhat curtailed, owing to the partial suspension at the mines on Monday, Columbus Day, which was generally observed particularly wherever the Italian element predominated. The demand at the present time seems to center on the household sizes, egg, stove and nut. Pea still lags, and buckwheat and rice can be purchased at considerably less than contract quotations. Just at the present time, there seems to be a slight dearth of orders for broken, but this situation will soon adjust itself.

Prices at Tidewater are as follows:

	Circular	Individual
Broken	$4.75	$4.50 @ 4.60
Egg	5.00	5.00
Stove	5.00	5.00 @ 5.10
Chestnut	5.25	4.90 @ 5.00

Bituminous—The dealers and manufacturers in this locality seem to be heavily supplied with soft coal, but there is considerable coal moving nevertheless. What the operators are really looking for is a speculative market with the consumer, instead of the operator, on the short end.

BALTIMORE

Conditions still far from normal. Domestic business generally flat, but export trade holds up well. Consolidation Co. reports a big half-year. Anthracite in but moderate call.

While considerable coal is now moving coastwise, both to New England and to the South, the figures are below normal and little new business is originating. The trade is confined to long standing contracts for the most part, and some of these have been seriously cut. To the West and Northwest there is the same story of heavy stocks and inability to place any more fuel.

Prices remain very poor. West Virginia gas three-quarter is still offering around 85 to 90c., run-of-mine at 75 to 80c., while slack has advanced somewhat under a better demand and is now commanding 40 to 45c. at the mines. Prices in Pennsylvania hold firm, low grades selling around 95c. to $1.05, medium coals at from $1.10 to $1.15 and the best grades at from $1.30 to $1.35.

The export business continues fair although the movement is not as extensive as in the middle of September. The report of the Consolidation Coal Co. for the seven months from Jan. 1 to Sept. 1, at a time when domestic business was admittedly flat, shows the effect of the heavy export trade, in which that company has played a leading role. The total output of the company for the period was 8,413,000 tons, as against 8,340,000 for the same period of last year, when home industries were demanding a record tonnage.

COAL CHARTERS

The "Journal of Commerce" reports the vessel situation as follows:

An active business was reported in steamer chartering, the major portion of which was for transatlantic voyages. Freights continue to offer steadily in several of the transatlantic trades, but as yet there is no appreciable increase in the demands of shippers in any other of the various trades. Tonnage continues to offer moderately, but not at any concessions in rates from those recently paid, and in some cases owners are demanding an advance over recent figures. For sail tonnage, there is but little inquiry in any of the various trades.

Coal charters have been reported as follows:

Vessel	Nationality	From	To	Tons	Rate
Angola	British	Norfolk	Phillipines	3179	
Isle of Jura	British	Baltimore	Havana	2485	
Kosfjord	Norwegian	Philadelphia	Sagua	961	
Agnes Manning		Philadelphia	Jacksonville	870	$1.00
Pendleton Sisters		Philadelphia	Calais	899	
Gemma	Italian	Virginia	Brindisi	1978	3.21
Ekaterini	Greek	Baltimore	Brindisi or Taranto	2414	3.24
St. Gothard	British	Baltimore	Puerto Padre and Sagua	1790	
James B. Drake		Baltimore	Galveston	991	
Dallington	British	Philadelphia	Cienfuegos	1613	
Olaf	Norwegian	Philadelphia	Mexico	1022	
Loring C. Ballard		Philadelphia	Boston	627	
Lovland	Norwegian	Baltimore	Port Limon	1463	
Santa Maria(bark)	Italian	Baltimore	Trapani	819	
Elizabeth T. Doyle		Baltimore	Robert Bay, Martinique	660	2.25

Note—Steamers are indicated by **bold face** type, all others being schooners.

COKE

CONNELLSVILLE

Market stagnant; only desultory negotiations; prices nominally unchanged. Production and shipments about 30% below top rate of year, while pig iron production generally has decreased about 20%.

The market continues stagnant, there being practically no buying of furnace coke and little of foundry. There are occasional negotiations on furnace coke, but nothing serious. One consumer has been inquiring about a 12-months' supply, but only on a sliding-scale basis, relative to pig iron. Foundry coke is a shade easier, but prices for standard grades are not quotably lower. Prompt furnace coke is nominal at $1.65@1.70, and contract at $1.75@1.85; various grades of foundry coke are available at $2 and upward, but regular standard grades cannot be had at under $2.25@2.35 for prompt, contracts being $2.35@2.50, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Oct. 3 at 249,152 tons, an increase of 1931 tons, and shipments at 253,852 tons, an increase of 5789 tons. The movement is now about 30% less than the average for several weeks in the early spring, when the maximum of the year was reached. In the same time pig-iron production in the country at large has decreased about 20%.

BUFFALO

Still much handicapped by the dullness in Canada. Reports continue of ovens shutting down.

The continued dullness of coke is very much against any immediate revival of the iron trade. Iron ore continues to come down by Lake at a good rate, but it is understood that much of it is contracted by the U. S. Steel Corporation, on which a royalty has to be paid this year, whether it is moved or not. For all that even those vessels are beginning to lay up, so that the Lake trade is not likely to be much of a success this season. Buffalo sells coke liberally to Canada when the demand is good, but the Canadian trade is very slack now. Coke ovens have shut down more or less all summer and are still being blown out.

BIRMINGHAM

There is no change this week in the coke market, business being extremely dull.

CHICAGO

Domestic coke is moving rather slowly. Prices are: Connellsville, $4.75@4.90; Wise County, $4.75; byproduct, egg, stove and nut, $4.95; gas house, $4.35.

ST. LOUIS

The market is unusually weak on foundry coke, at $5.30 for selected Connellsville 72-hr. On domestic byproduct there is very little moving in and no demand. The demand for local gas-house is improving. Quotations are: Wholesale, $4 per net ton f.o.b. tracks; retail, $5.75.

LAKE MARKETS

BUFFALO

Warm weather makes coal sales difficult and situation is not improved. Fair demand for anthracite. No prospect of good business in bituminous in the immediate future.

Bituminous—The warm weather of late would have made the sale of coal difficult even with a liberal consumption. With the full briskness lacking it is hard to keep ahead of the mine output. Slack is only a trifle stronger, because of the moving of a big supply that has been on the market some weeks and also to the light Lake shipments from Ohio ports. So much three-quarter is shipped by Lake, to the exclusion of almost any other size, that there is always an excess of slack thrown on the market during the Lake season. There is not quite so much complaint of coal waiting on track, but there is still sufficient to keep the price down.

The state of the bituminous trade is still controlled to a certain extent by the Pittsburgh circular of last spring, though in slack times there is more and more coal sold at concessions, $2.55 for mine-run and $2.15 for slack. Allegheny Valley coal is about 25c. lower than Pittsburgh.

Anthracite—In spite of the warm weather and the brisk movement of coal early in the season there is a good demand for all sizes except egg and some shippers report an improvement in that lately. Screenings have moved rather slowly, but that is on account of the warm weather. It will take cool weather to make the local trade brisk. The Lake trade is still quiet, but anthracite is much more active than bituminous. Some of the Buffalo shipping agents would forward more anthracite if they could get it, as they report that the Western trade is good and there is a fair amount of room on the upper Lake docks. Shipments by Lake from Buffalo for the week were 104,00 tons, nearly all of the clearances being for Chicago and Duluth.

PITTSBURGH

Sale of 60,000 tons of Lake coal. Market generally stagnant, mine-run at $1 and $1.15 for steam and gas respectively. Operations at about 50% capacity.

The coal market in general continues decidedly inactive, with prices as soft as formerly. While the Lake trade in general is very quiet, a sale of 60,000 tons of screened coal for this trade has just been made by a Pittsburgh shipper, shipments to begin at once and to be completed well before the close of the navigation season. Such sales have been relatively rare in the past few weeks, the requirements of the Northwest trade being easily covered by coal under regular contracts with mines. Retail demand is no more than fair for the season, and the line demand is if anything a shade lighter than a week or two ago. Railroad consumption shows no change. The total Lake shipments will be easily 25% under last year's record. Very slack times in the coal trade are expected when Lake shipments cease.

Prices continue quite irregular. The best gas coal is held with some firmness at about $1.15 for mine run, but steam coal runs off and down to about a dollar. Slack prices are rather irregular, averaging about 50c. a ton and with little signs of the firming up that should come as the Lake shipping season draws to a close. There is no talk of new circular prices being issued. The old prices remain: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.50, per ton at mine, Pittsburgh district. Mining operations are at little if any over 50% in the district, with prospects of curtailment in the near future as the Lake season closes.

TORONTO, CAN.

Domestic trade quiet but steam situation improving with the more encouraging business outlook.

The market for domestic coal continues rather quiet owing to the mild weather, and no active movement is anticipated until it becomes colder. Manufacturing conditions show some improvement as confidence returns and manufacturers in several lines are increasing their output. The call for bituminous for steam purposes is steady, with prices somewhat lower for carload lots. Quotations are as follows: Retail—anthracite egg, stove and nut, $7.75; grate, $7.50; pea, $6.50. Bituminous steam, $5.25; screenings, $4.35; domestic lump, $6; cannel, $7.50. Wholesale f.o.b. cars three-quarter lump, $3.78; screenings, $2.64.

TOLEDO

Toledo market continues inactive but with a strong undertone. Lake movement good. Fine coal difficult to dispose of.

The market remained practically unchanged during the past week. The warm weather has knocked the bottom out of the domestic trade so far as demand is concerned although prices have held up well and dealers declare that it will improve as soon as weather conditions are more favorable. The steam market has been a source of some discouragement as the demand is not what had been expected and the export business has not been as great as was hoped for.

However prices have remained fairly firm except on fine coal which is a drug on the market. The Lake movement continues fairly good but the ore business is light, as has been the case throughout the summer. But dealers here, however, are far from pessimistic in spite of these adverse conditions. Money is getting easier and investments of all kinds are showing a marked improvement over what they were shortly after the announcement of the European war.

COLUMBUS

Slowness still the feature in the Ohio trade. The domestic demand hinging on the weather. Steam business slack, but Lake trade showing some activity.

The domestic market in Ohio is now entirely a weather proposition, and because of the continued high temperatures there has not been much demand for domestic sizes. This condition, however, is only temporary, and jobbers as well as operators are not discouraged over the prospects. As a result of the slack demand, there has been a number of cancellations of orders, but the circular prices are still fairly well maintained, the only cutting reported being where stocks have accumulated.

The Lake trade is still one of the active features of the market. Bottoms are apparently plentiful, and a rush of coal to the Northwest will be made before the close of navigation. Docks of the upper Lake ports are generally in good shape and the interior movement is fair.

Steam business is as bad as ever, and there is no immediate hope for improvement. Many of the manufacturing plants are buying on the open market, being loath to enter into contracts under present conditions. Railroads are taking only a fair amount of fuel and steam contracts are not expiring at this time.

Retail business is at a standstill. Dealers have sufficient stocks to last for some time, and are not selling to any extent. The bulk of the stocking business has been done and it will require colder weather to bring customers into the market. Retail prices are being upheld, notwithstanding the stagnation, and little cutting is reported. There is a distinct preference for the better grades, such as Pocahontas and West Virginia splints. Anthracite is also in good demand.

Production in Ohio fields is not very brisk. The Pomeroy Bend district reports a normal output, but that is about the only field which has held up. The Hocking Valley produced about 75 per cent. of the average, and the same percentage is reported from Jackson, Massillon and Cambridge.

Prices in the Ohio fields are:

	Hocking Valley	Pomeroy	Kanawha
Re-screened lump	$1.70	$1.75	
Inch and a quarter	1.60	1.60	$1.50
Three-quarter inch	1.45	1.45	1.45
Nut	1.15	1.40	1.15
Mine-run	1.15	1.15	1.15
Nut, pea and slack	0.30	0.35	0.30
Coarse slack	0.20	0.25	0.20

CLEVELAND

Warm weather has reduced the demand for domestic sizes, and the small grades are not being made in such large quantities. Lake shipments are about over.

Retail dealers have cancelled and postponed contract shipments the last week because of the mild fall weather. This has resulted in mines producing less coal, and the receipts of slack have fallen off proportionately. The prices of domestic sizes remain unchanged.

In the steam grades, the demand does not seem to change. There are a number of factories working 24 hours a day, but these are largely blanket and woolen mills. One or two automobile factories are working to capacity, as are some of the chemical companies, but such plants do not use a great deal of fuel.

Fairmount operators offered three-quarter as low as 80c. at the mines, and mine-run at 65c. West Virginia No. 8 is being shipped to this market on consignment. Pomeroy nut and slack carrying $1 freight has been bought at 30c. by jobbers, while Panhandle has sold at $1.35 to $1.40. Hocking nut and slack are not being brought here, because it has not been satisfactory. This weaker tendency all along the line is only temporary, and orders for shipment are being taken at the prices current a week ago.

The Lake trade is taking boats subject to two weeks' storage before being unloaded. To meet this demand, shipowners who have taken cargoes of this kind will lay their ships up for a 15-day period, which entitles them to a refund of insurance amounting to about $750. This is the principal demand for vessels just now. Docks are not shipping enough coal to make space for current receipts and shippers are about through except for what coal they may send up in boats the last week or ten days. One company that takes in a cargo a day during the season has reduced this to one cargo a week. Canadian shipments are so light that one fleet of boats that usually carries a large amount of this coal has already gone into winter quarters. Three more docks went on single shifts last week, and by the end of this week all docks will be on this basis.

Prices for current shipment are as follows:

	Pocahontas	Youghiogheny	Bergholz	Fairmount	W. Va. No. 8
Lump	$3.75				
Lump, 6 in.			$2.45		
Egg	3.75				
Egg, 6 in.			2.10		
Lump, 1¼ in.		$2.40	2.25		
Lump, ¾ in.		2.30	2.10	$2.00	$2.05
Mine run	2.75	2.15	1.95	1.90	1.95
Slack	2.40	1.50	1.45@1.50	1.50	1.50

CINCINNATI

Domestic business is showing a slight improvement with the advance of the season. The steam market is still very dull. Lake movement has practically ceased.

The local domestic business is light, but considerably better than the steam market, which continues dull. Indications are not lacking, however, that this will not last much longer. But just now, as for several weeks, nut and slack is a drug on the market, being offered at the buyer's own price, and reports are to the effect that many operators are dumping it at the mines, without attempting shipment.

Domestic business is not what it should be at this season, conservative buying and selling serving to hold down the volume of coal handled. Dealers are not inclined to attempt to force sales, in view of the possibility of credit losses if the business depression continues, and consumers are awaiting cold weather before buying. So far there has been none, and with domestic storing below the normal, the amount of the prepared grades sold has not reached anything like its usual level.

The Lake movement has practically ceased. This is due to the disinclination of owners of boats to send their vessels up the Lakes without prospects of a return cargo. As a result, the volume of fuel to be disposed of in the rail markets is all the larger. Prices tend to show this, as might be expected, although the only substantial concessions reported are in steam coal.

SOUTHERN

BIRMINGHAM

Coal quiet. No developments in South American business.

The market for the past week or ten days has been rather quiet, especially on steam coal. Lump coal seems to be improving somewhat, due to the approaching cool weather, but steam coal is very quiet, the mines running only about 60 per cent. of full capacity. Nothing definite has yet been done regarding the South American trade, and it now seems that it is a matter of proper finance arrangements that is holding up the deal. The pig iron market is quiet.

LOUISVILLE

Domestic demand has eased off and the situation is less favorable. Mine operations further reduced.

The one bright spot in the Kentucky coal market, the demand for domestic sizes, has disappeared because of the unseasonably warm weather. As a consequence the mines in both the eastern and western parts of the state are not operating to more than half capacity. Improvement is noted to a degree in general conditions and several of the operators express confidence that things are now at their worst. Here and there coal men note that they are receiving inquiries from the South for industrial needs and are taking heart.

The Kentucky market, however, has been invaded by the Tennessee state, convict-worked mines, which are shipping by the Southern Ry. which heretofore had done very little coal carrying in this market. This coal is underselling the commercially-mined product. The local domestic market has been helped some by the low stages of the river which have prevented heavy shipments of Pittsburgh coal.

MIDDLE WESTERN

INDIANAPOLIS

Mining much below normal for October, due to the summer weather. Mines generally on only about half time.

The weather has continued warm, with the temperature between 65° and 80°, and this has lessened the demand for the domestic grades, which have been the chief factor in the trade, and caused a general weakening effect all around. Operators estimate that the mines throughout the state are not doing better than three days a week. There is no improvement in the railroad or factory demand, and the steam-coal trade is much below normal for October.

It is said that the customary advance of 10c. to 15c., Oct. 1, has been abandoned on account of the unfavorable weather and other adverse conditions. Retailers are selling at the same prices that have prevailed. It is believed by many in the trade that normal conditions will hardly return before the first of the year, unless the unexpected happens, either at home or abroad.

CHICAGO

Weather conditions have resulted in light buying. Little change in the anthracite trade. Demand for Hocking coal has slowed up. Indiana operators handling a fair tonnage of domestic business, with prices reasonably firm.

The buying of both domestic and steam coals continues light, and the anthracite trade is just holding its own. In the smokeless market, conditions have been slow, but not soft. The major operators have been holding firmly on small sales to $1.40 for mine-run, while the smaller producers and shippers of off-grade coal are accepting less prices, usually around $1.25. The demand for lump and egg is still strong, but the output is light because the production of slack is so small. There has been a decided recession in the demand for Hocking coal; some of the operators have also been overshipping this market and some of the lump coal is getting up to demurrage and being sacrificed in order to move it. The circular price is $1.60.

There has been, for the first time, some easing up in the price of splint. For a while, so much of that coal moved to

the East that Western prices remained firm, but within the last week the movement to the West has increased and quotations are lower. Springfield operators report no improvement in business. Indiana operators are having a fair run of domestic business, with prices reasonably firm.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.57	$3.05	$2.52	
Steam lump	2.02		1.97	
Egg		2.80		$4.30
Mine run	1.87	2.15@2.25	1.87	$3.30@3.45
Screenings	1.07@1.12	1.40@1.50	1.07@1.12	

Harrisburg quotations are: Domestic lump and egg, $2.80; steam lump, $2.20; mine-run, $2.15; screenings, $1.40@1.50; No. 1 nut, $2.80; No. 2 nut, $2.40.

Carterville prices are: Lump, $2.80; egg, $2.65@2.80; No. 1 washed, $2.80; No. 2 washed, $2.40.

ST. LOUIS

Market continues dull, though there are signs of an improvement. Warm weather adversely affects the domestic sizes.

The past week has been an unusually dull one, and it was somewhat unexpected. The steam market still continues as it has for the past two weeks, but indications are that the next week or ten days will see it considerably improved. The domestic market is still strong on lump, but the other sizes are weakening. This is due principally to the warm weather.

Anthracite still continues to move in, and is in good demand, both in the city and country. Smokeless continues a drug on the market and can be had at the purchaser's own price. While the market is in poor shape at this time, everything indicates higher prices soon.

The prevailing circular is:

	Williamson and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	.....	....	$1.25	$1.10@1.15	$1.15
3-in. lump	.....	....	1.40	....	.....

KANSAS CITY

Open weather the past week permitted more liberal deliveries of coal to householders. Prices remain unchanged, but an increase seems likely soon.

Several weeks of rain, which hampered deliveries of coal, were followed last week by clear and cooler weather. Orders were stimulated, and coal moved more nearly in its seasonable volume. If the present movement continues unabated, it is predicted that the prices will be increased the coming week. Plenty of cars seem available now, and dealers are beginning to stock up against a possible shortage. Pennsylvania anthracite is moving better than any time this fall; there is said to be but little stored in this vicinity, not enough for reserve against a probable heavy demand.

Mine prices have been adjusted somewhat in the past week, after the general increase on many products three weeks ago. Lexington fancy block has gone off to $2.10, and Richmond and Camden domestic block to $2. Southern Kansas nut is $2.10, mine-run steady at $2, mill-run $1.60, and slack $1.35. Leavenworth lump, fancy lump and egg have advanced 25c. to $2.50, $2.65 and $2.50, respectively; while mine-run has gone up 10c. to $2.25 and nut 20c. to $2.35. Higginsville Old Glory is quoted at $2.10 to $2.50. Iowa coal is 10c. higher, at $2.10. Illinois fuel is holding its strong prices. Arkansas semi-anthracite has reached the top at $3 for fancy lump, $2 for mine-run and $1.40 for slack. Arkansas semi-anthracite briquetts have reached the $5 winter basis. Pennsylvania anthracite has advanced 30 to 60c.

PORTLAND, ORE.

Rumors that Great Britain has taken over a cargo of West Virginia coal. Market quiet.

From Seattle came the report this week that the American steamer "Montoso," which had just arrived there from Norfolk, Va., with a cargo of 3970 tons of coal, has been ordered to Equimault, B. C., to discharge. It is understood the coal was purchased on short notice by the British Admiralty for use at the Esquimault Navy Yard.

The local coal market is fairly active and prospects are regarded good for the winter. There has been no change in quotations in past month. Coal briquettes are gaining in popularity for domestic purposes here. They are selling at $9 per ton, delivered in one-ton lots.

Coal Contracts Pending

Contract No. 1—Columbus, Ohio—The Ruggery Building is in the market for 300 tons of West Virginia slack coal. Shipments are to be made at the rate of 25 tons per day, beginning Nov. 1, delivery to be made at Columbus, Ohio. All communications should be addressed to J. A. Shahan, 60 Ruggery Building, Columbus, Ohio.

Contract No. 2—Norfolk, Va.—The United States Government is in the market for 2000 tons of bituminous coal. All communications should be addressed to E. Eveleth Winslow, Lieutenant Colonel of Engineers, United States Engineer Office, Norfolk, Va.

FOREIGN

Chile, South America—Press reports state that Chile will probably be asking for bids for 300,000 tons of coal per annum for three years.

Argentine, South America—There are unconfirmed rumors to the effect that inquiries are being made for fuel to coal the Argentine Navy.

British Guiana, South America—The Pittsburgh foreign trade commission announces receipt of a request from the government of British Guiana, asking for bids on 5000 tons of bituminous coal, shipments to run over the next year. Unconfirmed reports state that tentative figures that accompanied the request for information, named considerably higher prices than are obtainable in the current market, in addition to which a substantial bonus is offered for prompt shipments.

Guayaquil, Ecuador, South America—La Compania de Alumdrado (Lighting Company) is in the market for 3500 tons of gas coal. Prospective bidders should state the specific gravity weight per cubic foot, and space occupied by one ton of gas coal. Give approximate analysis including moisture, fixed carbon, sulphur and ash, and a commercial analysis showing the gas per ton of coal, gas per cubic foot of coal, illuminating power of the gas in standard sperm candles, value of one cubic foot in grains of sperm, sperm value per ton of coal, coke per ton of coal (good quality), coke per cent. of coal, ash in coke, sulphur eliminated with the volatile products, sulphur in the coke, tar per ton of coal. Quotations should be c.i.f. Guayaquil. Address The Manager, Compania de Alumdrado, Guayaquil, Ecuador, South America.

COAL CONTRACTS LET

East St. Louis, Ill.—Swift & Co., recently contracted with the Rutledge & Taylor Coal Co., of St. Louis, for two cars of screenings daily until Mar. 31, 1916, and also with the Breees Trenton Mining Co. for the same tonnage under the same delivery conditions.

PRODUCTION AND TRANSPORTATION STATISTICS

VIRGINIAN RAILWAY CO.

Shipments over this road for June, July and August with details of leading operators were as follows in short tons:

Shipper	June	July	August
Knw., Glen Jean & E. R.R.	32,920	24,084	22,588
E. E. White[1]	26,073	29,424	34,884
Gulf Smokeless	21,869	22,294	26,028
Loup Creek Colliery	20,717	19,139	18,389
Slab Fork	19,811	20,544	27,523
New River Collieries	19,244	8,906	17,172
Pemberton Coal & Coke	17,253	18,212	20,242
E. E. White[2]	16,253	18,788	21,631
McAlpin	14,324	14,906	14,447
Windin Gulf Colliery	13,278	14,268	18,938
Long Branch	12,454	10,545	17,789
Bailey Wood	11,707	11,544	13,141

[1]From Glen White. [2]From Stotesbury.

Gross shipments from all mines totaled 361,906 tons as compared with 286,354 in August, 321,626 in July, and 321,181 tons for June of the current year.

I. C. C. No. 5036—Empire Coke Co. vs. Buffalo & Susquehanna R.R. Co.

1. Rates for the transportation of coal from mines in the so-called Clearfield region of Pennsylvania to Geneva, N. Y., not found to be unreasonable or unduly discriminatory.

2. The withdrawal of a rate of $1.25 per ton applicable only on coal to be coked in transit at Geneva, N. Y., held to have been justified by the carriers on the ground that it was a preferred rate to a single city and industry and was not in fact a true milling-in-transit rate. Complaint dismissed.

FOREIGN MARKETS

GREAT BRITAIN

Prices improving and export business becoming more normal. The pit-prop question still unsolved. Retriction in exports from other European states.

The London trade, especially for house coal, still continues quiet. The colder weather, however, has given a stimulus to the actual consumption, and a little more buying has been apparent. Public prices advanced 24c. per ton Sept. 26. Colliery prices are all advancing, and special quotations are now withdrawn. Many collieries still refuse to quote for standard qualities, as they have so many orders on hand. The seaborne trade is slowly mending. Manufacturing coals are firm, but slacks and small nuts are offering freely at considerable reductions.

The coal trade of the Tyne is reported to be stationary, and prices are difficult to maintain. On the other hand, a slight improvement in the household trade is again noticeable in the Lancashire market, while in Yorkshire the position is fairly firm, business having reached expectations. The Cardiff market has been quiet and irregular during the week, there having been less shipment.

Ever since the outbreak of the war, the pit-prop question has been to the fore among the many difficulties which have beset colliery managers. A commission, representing the Board of Trade, the Mining Association of Great Britain and the Timber Trade Federation, has now proceeded to Canada and Newfoundland to inquire into the possibility of opening new sources of supply in those places.

The British Engineers' Association has complained to the government regarding the inadequacy of the measure for controlling trade with the enemy. The association is of the opinion that the regulations should be more stringent.

Holland has prohibited the export of coal, coke and briquettes, and Switzerland has placed an embargo on the export of fuel of all descriptions. The Board of Trade is in receipt, through the foreign office, of telegraphic information to the effect that the Portuguese Government has authorized the exportation of pitwood from Portugal to the United Kingdom so long as there is no shortage of these articles in the home market.—"The Colliery Guardian."

Oct. 2—The market is dull and featureless. Most qualities are freely offered and concessions can be arranged where buyers are able to take prompt delivery. Quotations are approximately as follows:

Best Welsh steam	$4.08@5.28	Best Mountmouthshires	$4.08@4.20
Best seconds	4.32@4.56	Seconds	3.96@4.08
Seconds	4.20@4.32	Best Cardiff small	1.92@2.04
Best dry coals	4.32@4.56	Seconds	1.20@1.56

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both net, exclusive of wharfage, and for cash payment.

Freights—Chartering is fairly active and rates for the Mediterranean are firmer. For South American destinations, the market is dull and featureless. Rates are approximately as follows:

Gibraltar	$1.68	Aden	$2.22
Malta	1.68	Colombo	2.34
Marseilles	1.76	Sabang	2.34
Algiers	1.56	Singapore	2.52
Genoa, Savona	1.96	Las Palmas	1.68
Naples	1.74	St. Vincent	1.80
Venice, Ancona	2.10	Rio Janeiro	2.94
Alexandria	1.92	Monte Video	2.64
Port Said	1.86	Buenos Ayres	2.88

SWITZERLAND

Coal imports for 1912 and 1913 were as follows:

	1912	1913
Germany	1,489,039	1,590,577
Austria-Hungary	7,449	5,340
France	218,149	196,934
Belgium	152,836	130,494
Holland	17,502	15,750
Great Britain	27,095	30,358
Total	1,912,070	1,969,454

In addition 439,495 tons of coke and 968,530 tons of briquettes were imported, nearly the whole of which came from Germany. In 1912, 411,288 tons of coke and 864,402 tons of briquettes were imported.

SPANISH IMPORTS

Spanish imports of coal for the first six months of this year and last year were, in metric tons:

	1913	1914
Coal	1,466,532	1,329,095
Coke	183,298	192,085

FINANCIAL DEPARTMENT

Pond Creek Coal Co.

President Thomas B. Davis, of this company, reports, in substance, for the year ending Dec. 31, 1914:

Development and Construction—Seven mines have been operated continuously throughout the year. From these seven mines there have been produced up to the end of this year 566,965 tons, and your company is in a position now to largely increase the output. The tonnage mined during the year exceeds the estimates of the management, and it has been very generally stated by authorities that your company's production for the first year after shipments commenced, constituted a record. Actual work has been in progress about 20 months, and all of the mines did not begin to ship coal until January, 1913, or later. While the seven mines now in operation are not developed to their full capacity, they are able to produce a much larger tonnage of coal than they did last year, and the production will be increased as markets are found for the coal.

The company now has completed construction work as follows: 52 four-room houses, 41 five-room houses, 13 six-room houses, 1 seven-room house, 259 eight-room houses, 1 ten-room house, 1 twelve-room house, three stores, power plant, power, light and telephone lines, five miles of railway sidings, six substations, seven fans and fan houses, warehouse, machine shop, six mine repair shops, two Y. M. C. A. buildings, and has done much construction work in the way of building retaining walls to keep creeks in their channels, constructing and improving roads and other construction work.

The company has purchased equipment as follows: 33 mining machines, 7 fifteen-ton electric locomotives, 16 six-ton electric locomotives, 816 steel mine cars, mine pumps, repair-shop tools and machinery and other equipment.

Transportation—During the current year the Norfolk & Western Ry. Co. completed the construction of their Williamson and Pond Creek branch at an estimated cost of $1,200,000, including the cost of a bridge across Tug River and yards near Williamson. This branch represents a high-grade piece of railroad construction work, and the road is built strong enough to handle very large tonnages of coal.

The Norfolk & Western Ry. service during the past year has been all that your company could have desired. It is the more remarkable that the Norfolk & Western Ry. Co. should have been able to give practically a full supply of cars at all times, considering the difficulties under which they labored during part of the year, on account of the tremendous damage done to their properties by the abnormal floods of April, 1913.

Your company is assured by the management of the Norfolk & Western Ry. Co. that the present standard of service will be continued in the future.

Distribution of Coal—The coal of the Pond Creek Coal Co. was tested out with very satisfactory results by some of the largest users of coal in this country, and it has been amply demonstrated that the coal is not only highly appreciated as a desirable coal for byproduct coking purposes, but also for use in the production of illuminating gas and for steam and domestic purposes.

In ordinary times a coal of the character produced by your company is always in good demand, and should be marketed without much difficulty.

Financial and General—The proposed plan of financing, referred to in last year's report, was adopted by the stockholders at their annual meeting on Apr. 9, 1913. The issuance of $3,000,000 of 6% bonds, secured by mortgage and convertible into stock at $25 per share, and the increase in the authorized capital stock of the company to 350,000 shares, were approved. Bonds to the amount of $2,000,000 were issued and the money was paid into the company's treasury June 3, 1913. Your company now has the financial ability to develop its properties to a capacity of 10,000 tons per day. The actual date when this tonnage will be realized is, of course, some distance off, as development to such a capacity requires time.

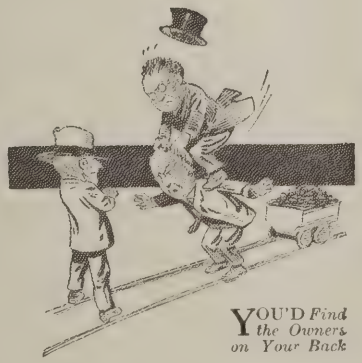
BALANCE SHEET

Assets		Liabilities	
Real estate	$1,001,508	Cap. stock issued	$2,000,000
Const. and devel.	1,619,709	Share-prem. account	250,000
Equipment	430,594	Convertible bonds	2,000,000
Cash	1,018,483	Accounts payable	115,063
Accounts receivable	99,531	Other misc. items	36,497
Inventories	230,350	Funds and reserves	10,180
Deferred charges	11,563		
Total	$4,411,740	Total	$4,411,740

Note—For previous annual report of this company see "Coal Age," Vol. 3, p. 980.

COAL AGE

Vol. 6 NEW YORK, OCTOBER 24, 1914 No. 17



If---

By BERTON BRALEY

Written expressly for
COAL AGE

SOME *Guys would Play you for a Dupe*

YOU'D *Find the Owners on Your Back*

IF YOU was Supe of all the mine
You know just what you'd do,
You'd allus treat the miners fine
An' boost their wages, too,
YOU'D never rage around an' damn
A lazy miners' group,
YOU'D be as gentle as a lamb,
If you was Supe.

I KNOW, you'd make the old hole pay
Much better than it does,
You'd run her in a diffrunt way
You'd make her fairly buzz,
An' while you cut th' cost of coal
The wages you would whoop,
You'd be a Great an' Noble Soul,
If you was Supe!

AN' yet, I ain't exactly sure;
You MIGHT find out, you know,
That while your motives they was pure
An' clean as driven snow,
SOME guys would think yer kindness weak
An' play you for a dupe,
Or say you had a yeller streak,
If you was Supe.

YOU'D find the owners on yer back
Demandin' cent per cent,
An' labor leaders on yer track
Who'd never be content,
An' costs an' loss an' such would come
In quite a nightmare troop,
To put yer think-tank on the bum,
If you was Supe.

YOU'D find the job was pretty tough
An' full of care an' fret,
An' now an' then you'd act up rough
Like other supes you've met,
The one we have is kinda grim,
An' if you bossed the coop,
You MIGHT be just as bad as him,
If you was Supe!

Clean-Up Month

"Buy American-made Goods" is heard all over the United States. In the South, "Buy a Bale" and "Wear Cotton Goods" are popular slogans. And while the "Buy a Bale" movement will not move the cotton crop, it has a helpful value in expressing the willingness of Americans to aid one another in keeping business going. The purchase and use of American-made goods will be of tremendous value in increasing production and distribution of homemade products.

THERE has never been as much sentiment attached to the coal industry, as to the business of raising cotton. The one is an industry of hard facts and hard work, while the other has more or less of romance attached to it. When there is no market for coal the mines shut down and the workers, like the owners, simply shift the best they can until the demand comes again. People would not come forward in response to a slogan such as "Buy a Car of Coal" as they have to that of "Buy a Bale of Cotton," although coal will keep as long as cotton and more people are dependent on the industry.

But the owners and operators of coal mines, whether individuals or stockholders, are also facing serious problems. Many companies must curtail expenses, policies of retrenchment are in order, methods of strict economy must be observed; for when a mine can run but half or three-quarter time, it is a hard pull to keep ahead of fixed expenses coupled with the cost of such operations. Coal people need a slogan.

Those who run coal mines and study cost sheets know there are two great factors of expense, labor and material. The mines must be run with the least number of men essential to safe operation, and in times like these, they usually are. But wages will not be reduced until all other means are exhausted.

The second factor, that of material, can be given more vigorous treatment because here no individual or family is so vitally affected as when a man is laid off or his wages reduced. The slogan for mine operators, therefore, lies in the handling of this factor.

It is common knowledge that when times are good the censorship on orders is less rigid. There are coal-mining concerns in America—some of them among the best—who have more material in their storehouses than they dream of. These excess supplies include a large number of costly machinery spares. There is many a scrap pile that contains good material that could be used to advantage in case of necessity.

In times like these, practical things are the only things worth while. Here is a practical idea for coal-mining companies.

Discover what you have on hand and use it now instead of continuing to order new material as you always do in good times. This idea can be expressed in the term "CLEAN-UP MONTH."

It can be carried out like this—

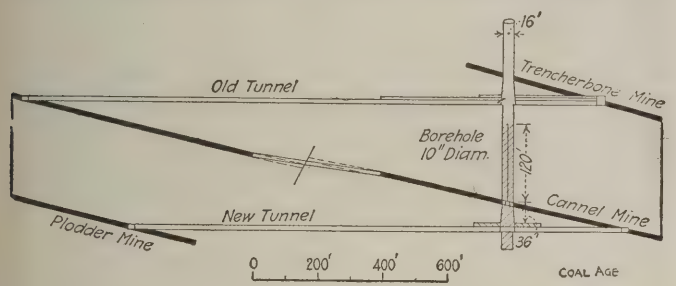
Institute a "CLEAN-UP MONTH" when no orders will be passed except for absolute essentials such as lubricants, explosives, etc. To make this effective, the supply house and storerooms about the mine should be carefully canvassed so as to exhibit all excess and obsolete or semi-obsolete stock; in fact, to show up what is on hand in the way of material that is always passed up in good times because it is easier to order more, but which is just as good as new if the men are made to use it.

Have the so-called scrap piles gone over thoroughly for good material suitable for use in emergency repairs. Many a superintendent has instilled ideas of economy into his master mechanic and made him fit to take care of minor breakdowns without rushing to the supply house for a new part. In fact, the best test of any man is the use he makes of what is at hand, rather than what he can do if given everything to work with.

The whole idea in "CLEAN-UP MONTH" will simply be to stop for a while the practice of ordering and using new material just because one can, when there is already something on hand that will do just as well. The adoption of such a slogan by coal-mining companies will be worth as much to them as the "Buy a Bale of Cotton" movement is worth to the cotton growers.

How many will try it?

Excavating Upward



By J. F. Springer*

SYNOPSIS—In a certain English colliery it became necessary to extend an existing shaft in order to reach a lower coal measure. This work was accomplished from below, thus avoiding interference with hoisting in the original shaft.

We are so accustomed to think of shaft excavation as progressing downward, that we must regard the opposite procedure as truly novel. Not long ago, in an English coal mine, a considerable length of vertical shaft was opened from below upward.

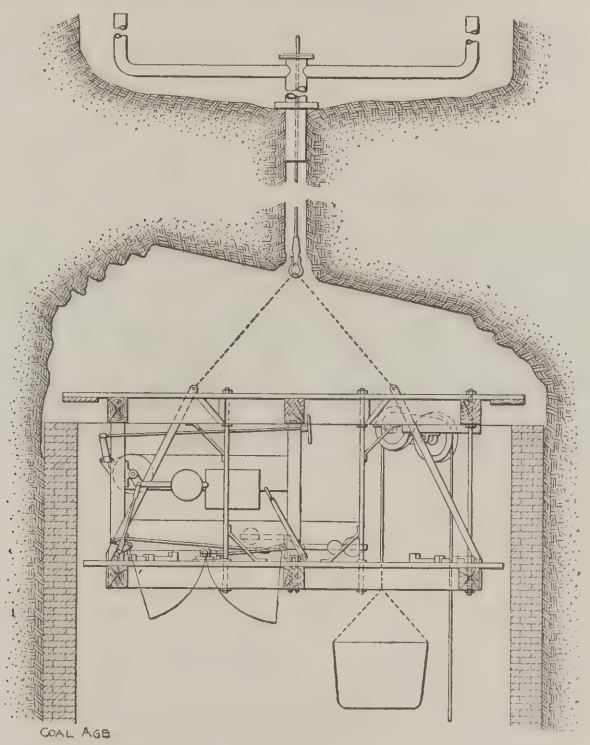
At Newton Colliery, there are several coal seams which are sharply tilted. Two of these were, a long while back, worked from a single vertical shaft, which connected near its bottom with both seams by a horizontal tunnel. That is to say, the shaft penetrated through one seam to the strata lying between the two, but did not go down far enough to reach the lower measure. The horizontal tunnel met the coal stratum at a point a considerable distance to the north where the seam rises to a sufficiently high level.

The tunnel was used until the exhaustion of the coal easily accessible became more or less imminent. It was then desired to construct another horizontal tunnel 195

Cross-Section through the Coal Measures

ft. further down and to deepen the old vertical shaft to or below this level. The new tunnel would then afford connections with two of the tilted seams, though not precisely the same two as was the case with the upper tunnel.

If the shaft had not been in active use for nearly the entire daily period of 24 hr., when the time came to deepen the shaft, the operation would have been quite simple. What was actually done was as follows: The tunnel was driven from the proper and accessible level of one of the seams, and the deepening of the shaft was carried out, in the main, from below upward. The work on the shaft extension was in this way carried out with but little interference with the operation of the shaft itself.



The point where work was commenced was not in the lower tunnel, but 36 ft. above it, where the lower one of the two original, tilted seams intersected the prolongation of the old shaft. The seam was now worked out in part and so there was suitable access. Between this point and the bottom of the shaft above was a vertical distance of about 120 ft. This region was now attacked by excavating upward.

*618 W. 136th St., New York City.

A bore hole was put down from the bottom of the shaft to the place of beginning the work. This served to make it possible to use a plumb line and thus fix the position with some certainty. It served also as a means of ventilating the upcoming shaft and to furnish a way of using a cable in carrying on the work.

The putting down of this bore hole was accomplished without interrupting the operation of the old shaft. The workmen were protected by means of a strong cover. The material brought up to the bottom of the shaft was so slight in amount, that it was readily removed during the few hours when the shaft was free from its ordinary use.

Let us now proceed to the upward excavating operations. A double scaffold was employed by the excavators and other workmen. This was swung from a cable through

The Arrangement for Making Excavations Upward

the bore hole whenever it was necessary to move it. When at rest, the scaffold was secured in part by means of pins or prids, which were advanced radially from the scaffold into the shaft walls. Additional support was provided by packing up from the top of the brick lining of the shaft.

There were two floors to the scaffold, both circular. The lower one was of less diameter in order to allow for the presence of a brick lining wall in the shaft. The top deck was used by the excavators, and from it they drilled the holes for blasting, the most of which were nearly vertical. The trimming of the side walls was also done from this floor.

The lower floor provided support for the bricklayers working on the lining. The space between the two floors was left open, except that on one side the upper and lower floors were connected by walls. In this way a box-

like compartment, 5x5 ft. in plan, was constructed.

Through the lower floor, opposite to the box, a hole 5x5 ft. in dimensions, was cut. The bottom of the box was a kind of trap-door, there being two leaves there installed opening downward. These leaves were normally held in place by heavy counterweights, heavy enough to prevent them from opening when only the weight of a workman was to be sustained. In addition, a strong screw brake and two trigger-catches were provided.

The men who worked on the top deck got to their positions from below by means of two openings in the sides of the box. In the space between floors, the pulleys were arranged, by means of which a bucket was raised and lowered through the 5x5-ft. opening in the lower floor.

The mode of operating was about as follows: The excavators would be hoisted in the bucket to the lower floor, whence they would pass into the box and thence to the top deck. They would get their blasts ready, and then withdraw to the bottom of the shaft. From this point or one off to one side, the explosives would be discharged.

The muck would fall onto the top floor of the scaffold or into the box. When the excavators returned to the lower floor, they either went through the openings in the walls of the box to the upper floor; or, if the way was blocked by the presence of muck in the box, by means of emergency doors. The upper deck would now be cleared by getting the material into the box. This latter was then discharged through the two-leaved door.

It should be understood that whenever drilling was begun, the upper floor of the scaffold rested on the brickwork. The men doing the excavating would use props to protect themselves from the roof overhead. It is said that the drilling went on rapidly because the drills working overhead cleared themselves automatically.

It was important that no fastenings or other necessary accessories should be out of place; so the men—especially the foreman—would make sure of everything as they started in after each blast. Thus, it was a matter of considerable importance that nothing should go wrong with the two-leaved door.

As it was desirable to use the bottom of the old shaft overhead as a sump, a pipe was put into the upper end of the bore hole and sealed on the outside with clay and concrete. It was only necessary that the upper end of the pipe should project a little above the maximum level of water in the sump. If conditions had been such as to prohibit the presence or the drilling of the bore hole, the recurrent necessity of lifting the scaffolding could have been satisfied by means of jacks.

Safeguarding the Repair Pit

By Pennsylvania Mining Engineer

The pits constructed for the purpose of cleaning and repairing mine locomotives and coke machines are among the dangers encountered in and around coal mines. Frequently these pits are from 3 to 4 ft. deep and are walled up with stone, brick or concrete. Often, too, the edges of these walls are left sharp, and a fall into the pit might easily result in a serious or fatal injury. To avoid such an occurrence, the pits are frequently covered with planking or metal sheets. In either case, however, such covers are hard to handle. Wooden covers furthermore in time become more dangerous than no cover at all, due to the rotting of the timber.

To avoid the danger of an open pit at a certain plant of which I had supervision, I, with the aid of my blacksmith and machinist, designed the folding railing shown in the accompany illustrations. When finished, in place and properly painted, this railing rather adds to than detracts from the appearance of the coke plant.

As may be seen in the photographs, such a railing was not hard to make, being built of second-hand pipe, and in the absence of fittings, 2x½-in. flat iron bands. The 8 upright pieces of pipe, located two at each corner of the pit, are allowed to project 6 in. above the upper horizontal rail. Over the end of adjacent uprights is slipped a shackle or tie, which holds the side and end sections of the railing in a proper position. Removing these shackles allows the four sections of the railing to swing outward from the pit on hinges attached to the top timbers or to the web of the rails.

The Railing in Position Protecting the Pit and Folded Down to Allow Locomotive or Coke Machine to Pass Over

I have installed similar railings at other mines, and can say from experience that after one of these railings is once placed, it gives no further trouble and answers its purpose admirably. If kept properly painted to protect it from the sulphur smoke, which attacks all iron structures around a coke plant, it will last indefinitely.

When there is a repair pit to be guarded, it is far preferable to construct a suitable railing and see that the same is properly put in place and operated, than to put the job off until a coke-machine runner or some other valued employee has walked into it and broken his neck. The expense of installing such a railing as has been above described is small and may readily be the means of saving a doctor's or an undertaker's bill, a law suit or two, and possibly an indemnity; but what is vastly more important, it may save the life of a trusted and valuable employee.

Meeting of the American Institute of Mining Engineers

SYNOPSIS—The meeting of the American Institute of Mining Engineers in Pittsburgh, Penn., Oct. 8 to 10, was an unqualified success and showed that the field of coal, petroleum, iron and steel was as fertile as any the institute has ever cultivated.

On Oct. 8, the committees of the American Institute of Mining Engineers devoted to "Coal and Coke," "Petroleum and Gas," "The Use of Electricity in Mines," "Nonmetallic Minerals," "Iron and Steel," held a joint meeting in Pittsburgh, Penn., with headquarters at the Hotel Schenley. About 200 members were present.

At 2:30 p.m., a general session was held in the Lecture Hall of the Carnegie Institute, in the rear of the Museum. L. C. Morganroth read a paper on "The Occurrence, Preparation and Use of Magnesite." This is one of the bodies which comes to us from Austria and Hungary and the discussion seemed to favor the idea that it should continue to come from that source until better deposits than those existing here are discovered. Only a temporary use of native deposits could be expected, that use ending with the war.

The paper on "The Oil Fields of Mexico," by Ezequiel Ordoñez, was left for the meeting of the petroleum section on Oct. 10. That on "The Iron Industry in Brazil," by E. C. Harder, was read by the secretary, Bradley Stoughton. Geo. S. Rice delivered his own paper in brief, entitled "Investigations of Coal-Dust Explosions."

Field Dirt for Immunizing Coal Dust

William Griffith desired to know whether field dirt had ever been used in the experiments for purposes of immunization. He said that mines did not have the crushing facilities needed for the making of stone dust and that the progress of the immunizing movement was held back by the idea, correct or incorrect, that the dust must be extremely fine which is used for that purpose. Until the Bureau makes experiments, as he showed, it is impossible to know just what are the indispensable specifications.

The paper of H. M. Chance was read only by title, as the author was absent. It was entitled "The Appraisal of Coal Lands for Taxation." R. V. Norris replied, stating his preference for a system of taxation on output. In rebuttal it was pointed out that while such a method might be reasonably equitable in the anthracite region because the companies were in general seeking to produce a maximum production, it was manifestly unjust in those portions of the country, in fact in all the bituminous-coal regions, because coal land tended to be held for a rise in value and consequently would not come into the market at all, if it were not taxed. In fact, taxation is desirable, as much for its liquidation of property as for the revenue it raises.

An Example of Freedom from Land Taxation

One of the principal untaxed offenders is the federal government, which has put a paper value on coal lands which would be swept away in a year by an indignant people if they had to pay taxes on their holdings, such as are paid by individual owners and operators.

R. V. Norris stated that the assessment of the coal in the anthracite region up to 1907 was on the basis of $10 per foot-acre. Then the various counties increased it arbitrarily in some instances up to $65 per foot-acre. They limited their assessments only by their taxation needs.

Taxation As a Veiled Robbery

In township of Hanover, Luzerne County, Penn., 97 per cent. of the taxes are obtained from the coal operators and owners, and that township recently spent $200,000 in building two miles of highway. Mr. Norris mentioned an instance where the taxes on a piece of coal land were now $2000 more per annum than the royalties which it realized. Owing to taxes being raised 163 per cent., the owner is the poorer every year by $2000, because of his ownership of the property, yet he cannot break the lease.

There has been much contest relative to the assessment in the courts of the anthracite district, and the Supreme Court has ruled that estimates based on the foot-acre are not valid. In fact, William Griffith declared that it was not safe for any expert to declare on what he based his valuation. The only appraisal which has never been successfully contested is based on the foot-acre and on a number of considerations equally invalid according to an opinion of the Supreme Court, but the basis has not been revealed and consequently no attack can be made on the validity of the results. Had the methods of valuation been exposed in the court, those methods, scientific and equitable as they were, would have been ruthlessly thrown out. The court accepted them not on the basis of reason, but on the ground of the Latin dictum "*experto crede.*"

The Income-Tax Inequities

S. A. Taylor called attention to the income-tax law for corporations. It permits, as administered, for 5 per cent. of the selling price of coal to be deducted from the profits for depletion of coal resources. This is ample in some sections of the country. On coal selling at an average of $1.20 per ton at the mine, the deduction amounts to 6c., but Pittsburgh coal can only be secured at 15 to 20c. per ton, so there is an inequity in this rule of from 9 to 14c. Whenever royalty is paid, however, the gross amount of that payment, however large, can be deducted without trouble being made by the U. S. Treasury.

In the evening, an illustrated lecture on "Ancient Methods of Manufacture of Iron in China," was read by T. T. Read, in the Lecture Hall of the Carnegie Museum. This was followed by a moving-picture lecture on "Safety Methods in Mining," by J. W. Paul, of the U. S. Bureau of Mines, who exhibited three reels, showing methods of mining at Nanticoke, Penn. Edwin Higgins, of the same Bureau, showed two reels, exhibiting the methods of iron mining of Witherbee, Sherman & Co., at Mineville, N. Y.

A few people visited the Allegheny Observatory and sighted the "double double" or Epsilon Lyrae and the

moon, through the 30-in. photographic refractor and the 13-in. refractor, respectively.

J. Taffanel's Regrettable Absence

On the second day, the party split into three parts, the "Iron and Steel," the "Coal and Coke" and the "Non-metallic" sections meeting separately. It will suffice to follow the discussion and papers of the "Coal and Coke" department. The first paper, that of J. Taffanel, on "Coal-Dust Explosion Investigations," was read by title as the author is a colonel in the French Reserves, and is needed at home. Liévin, where his experimental station is located, is at present writing on the firing line over which the Germans and French now pass back and forth in their death grapple.

H. N. Eavenson read a paper on "Coal-Mine Explosions Caused by Gas or Dust," and showed that the frequency of accidents from serious explosions, in which more than five lives are lost, is greatest in the winter months. Apparently foreign explosions do not show such a preference for cold weather. For instance, in Great Britain, while December leads in fatalities, June is second in this respect.

Increased Number of Accidents from Explosions

The author adds that "in the coal mines of the United States, the total number of accidents and of fatalities due to explosions of gas or dust has been steadily increasing; there has been a slight increase in the number of accidents and a more decided increase in the number of fatalities per million tons produced; the serious explosions, causing five or more fatalities each, having been steadily increasing in actual number and number of fatalities as well as in the number of accidents and of fatalities per million tons produced; the number of accidents per mine, both serious and total, also shows a steady increase."

Where America and Europe Differ

Geo. S. Rice called attention to the fact that the mingling of statistics of accidents from coal-dust and gas explosions had much to do with the showing which made summer conditions in some countries about as unfavorable as winter. He admitted, however, that a separation between those from one cause and another was almost impossible. He pointed out that most of the explosions in Europe were probably due to gas whereas in America, coal dust was perhaps the greatest menace.

R. D. Hall said that the very period of occurrence of winter in Europe is different from that in the United States. In fact, the last three months of the year are almost regarded as the winter in Europe whereas the first three are roughly so regarded here. One cause for the importance of coal-dust explosions in this country is the prevalence of room-and-pillar workings. The open faces in longwall leave room for release of violence in an explosion and dust explosions are not so likely to occur as they are where the blown-out shot or gas explosion originates in a restricted area, such as a heading, which resembles the bore of a cannon.

He called attention to the fact that longwall workings make ventilation difficult and consequently frequently cause gas explosions. For this, as also for other, reasons the mines of Europe are not as well furnished with air as those of the United States.

S. A. Taylor declared that it would be well to inquire into the possibility of gas being fired by the currents from wireless telegraph stations and said a recent British explosion had been ascribed to that cause.

H. A. Kuhn's paper on the "Pittsburgh Coal Field of Western Pennsylvania" was not read as he was not at the meeting to present it. The same is true of R. S. Lewis' paper on "The Book Cliffs Coal Fields, Utah," A. E. Gibson's on "An Aërial Tramway for Mining Cliff Coal," and M. B. Yung's on "Tin and Coal Deposits of the Fu Chuan District, China." Nor was there any discussion on these papers. J. P. K. Miller followed with his paper on "The Manufacture of Coke."

The Cement-Gun Work

At 12:40 p.m., the members of the "Coal and Coke" section took a special car to the Baltimore & Ohio R.R. station and the train to the experimental mine. It is perhaps unnecessary to add anything to what G. S. Rice and L. M. Jones will have to say in our next issue, relative to the demonstration at Bruceton, Penn. The cement-gun work attracted much attention and it might be well here to point out that unlike the sample work on the grounds, no reinforcement was used in its construction. The mixture of cement and sand in the proportion of one part cement to three parts sand was wetted with water at the nozzle and fired on the natural surface of the rock or old concrete which had to be covered.

This surface, though covered with soot and by no means ideal for bonding was not prepared for the reception of the gunite except that in places projections were broken off so as to make the surface less rough. It must be remembered that the gun itself sandblasts the surface. The rebound possibly moves much of such extraneous material as would interfere with bonding. This rebound of sand probably amounts to ¼ or ⅓ of that used so that the cement mixture is probably two parts sand to one of cement. The sand which rebounds can be used again as it does not bond together in any way, for it is free of cement.

Resistance to Explosion

The coating had stood a severe explosion prior to Oct. 9 when the members of the Institute saw it and it passed through the second ordeal with almost equal success. However, in the second explosion a patch about a foot square fell and this injury is supposed to have been due to putting on the coating too thick at one operation as it was two inches thick at that one point. The bonding had been made to bone coal.

Of course, the test for the cement gun is not an explosion test but one of weathering and the experimental mine is hardly the place for determining its value. There is reason to believe that the gun will prove useful for saving roofs from air-slaking. So long ago as 1911, G. S. Rice, the chief mining engineer of the Bureau, advocated a trial of its availability for such use.*

The Coal Men Were Silent

The other sections visited the McKeesport plant of the National Tube Co., the Homestead steelworks of the Carnegie Steel Co., and the Harbison-Walker brick plant. In the evening an informal subscription dinner was given at the Hotel Schenley in the Banquet Hall, S. A. Taylor

*"Some Special Uses of Concrete in Mining." Transactions of the National Association of Cement Users. Seventh convention. Vol. VII, 1911, p. 416.

presiding and B. B. Thayer, Bradley Stoughton, Charles F. Rand, Elmer Hiles, I. C. White, S. B. McCormick, George H. Neilson, Philip N. Moore, Edmund C. Pechin and E. G. Spillsbury being the speechmakers. Perhaps it would have been possible to give a little more prominence to the coal industry in the selection of speakers if only to compensate for long years of silence.

On Saturday morning, the 10th, three meetings were held, the "Petroleum and Gas" section, that of "Electricity and Miscellaneous Mining Topics" and that pertaining to "Iron and Steel." The first had two papers in which our readers will have no interest but the discussion which followed on gas and oil wells passing through coal seams has value to many coal men.

The Plea of the Gas Interests

The gas men endeavored to show that they had provided most liberally for safety. W. E. Fohl stated that investigation showed that every explosion of gas from wells which had occurred had been caused by naked lights, and he advised the use of electric lamps in mines in which an influx of gas from a well is to be anticipated. The suggestion is good but it is a folly to overlook the fact that explosions of well gas may not always be so caused, may even have already resulted from some other agency than an open light. There are several possible sources of ignition and using electric lights, though advisable, is an insufficient insurance.

"Bunching" Wells

As was stated, the gas and oil men have been placing their wells so close together as to interfere severely with mining. It might be possible to mine around a well symmetrically and let the measures fall without injury. But the frequency of the drilling makes this impossible and to leave an *adequate* pillar around such holes is an extremely expensive practice and one which spoils the mine and interferes with output.

It was alleged that the gas and oil men drilled altogether too many holes. Someone replied that no one went to the expense of drilling holes for recreation and the obvious reply was that this was not alleged. Excessive drilling is practiced because the oil or gas man desires a large output in a short time. He has, of course, just as much right to drill the earth like a sieve to hurry production as the operator has to keep him from drilling in order that he, the coal operator, can get out his coal without annoyance and danger. The rights are even. In fact, the majority of holes are by no means drilled "for fun," but for the purpose of removing the oil and gas from under the land of someone else or to remove the mineral wealth of one's own land so as to prevent it being purloined through the wells of another. As a matter of actual fact, excessive drilling has generally been considered a mistake and a source of loss to the industry as the pressure is reduced too rapidly and flooding results.

Rock Pressure Is Not a Sign of a Good Well

There is a general belief that a well of no value is always one of low rock pressure, but rock presure is a function of depth; of course it disappears in a well which is commercially valueless as soon as the gas or oil is allowed to escape but while the well is confined, pressure has little or no relation to the probable productivity of the well when the gate valve is opened. A worthless well thoroughly plugged will develop as dangerous a pressure as the most productive of oil or gas wells and protection is needed against leakage of gas from such a well as much as from any other.

How Much Rock Can a Gas Pipe Control?

The gas men believe that a little gas pipe surrounded with 2 or 3 in. of concrete will act as a pivot on which a million or more tons of rock will swing when the moment of collapse arrives. When at the Union Coal Co.'s mine, at Adamson, Okla., an area 1300x2600 ft. suddenly began to cave and 13 miners met death, what would have happened if a few gas lines with concrete facings stood in the way?

They would have snapped like the stem of a churchwarden pipe. Probably about a hundred million tons of rock fell when this Oklahoma mine let go. If only there had been a pipe with a concrete shell around it, what modification in the manner of descent of the rock would have been made by that fairy wand?

From such an atmosphere of misconception, one turns with relief to the meeting of the "Electricity and Mining Topics" Section upstairs. S. S. Rumsey and W. F. Schwedes had prepared a paper, entitled "A Test of Centrifugal Motor-Driven Mine Pumps." This was only read by title, but the discussion was animated, being led by the chairman of the committee on the "Use of Electricity in Mines," William Kelly. It was pointed out by R. V. Norris that a certain definite quantity and head for which the centrifugal pump should be designed should be provided if any efficiency was desired. Of course, by storage and interval operation the volume needed can be secured, but running the main station under varying load is uneconomical.

It was said that the reciprocating pump was also most efficient when working at a certain speed and passing a predetermined volume.

Centrifugal Pumps in Flooded Mines

Difficulty arises in the pumping of acid water. R. V. Norris declared that if it is extremely acid it cannot be handled with a centrifugal pump, but Edwin Ludlow declared that by lining the pumps with Mannheim cement, acid water and even slush could be handled. He regarded the centrifugal pump as excellent for the dewatering of flooded mines. Those over which he had charge had to handle 25 tons of water for every ton of coal mined, and as a great part of that water came in from the surface on the occasion of heavy rains, it was necessary to keep spare equipment for occasional use. The centrifugal pump being less expensive than the reciprocating unit was better suited to this purpose. His pumps had bronze parts throughout.

It was stated by one of those present that a German centrifugal pump had been ordered for shaft sinking. It was designed to lift water under any head from zero to 800 ft. The nature of the means by which this adaptability to varying heads was secured, he was unable to explain as he did not understand the construction of the pump.

Gasoline Locomotives and Health

"The second paper was on "Gasoline Locomotives in Relation to the Health of Miners," and was read by O. P. Hood, chief mechanical engineer of the Bureau of Mines.

His remarks, on the whole, seemed quite favorable to the use of such equipment. R. V. Norris urged that the locomotives be kept on the main entries and not allowed to enter chambers. He stated that carbon monoxide caused lesions of both brain and kidneys and did not have merely a temporary effect on the person who inhaled it.

G. S. Rice said that when he first saw gasoline locomotives in England, France and Belgium, he had been much pleased with their performance and had hoped for their introduction into this country. However, these foreign locomotives were of the hit-or-miss type of ignition and the power was low, only about 4 or 5 hp. They were used only on small grades. The American market demanded locomotives of more capacity and perhaps that is the cause of some ventilating difficulties.

S. A. Taylor stated that he found that the motormen were disposed to turn on too much gasoline whenever any undesirable condition increased the load and, as a result, imperfect carburetion took place. He said he had placed his gasoline locomotive in the return airway, and graded the road carefully so as to equalize conditions, but he found he got an excess of monoxide if an additional wagon or heavier loads made an unusual demand on the locomotive.

W. G. Whildin said that he had used four different types of gasoline locomotives and found them uncertain in operation. He had found little trouble from imperfect carburetion, the miners and the motormen not being affected, although one morning, on starting, all four men were overcome and needed the pulmotor.

Advocates Carburetors Used in Automobile Practice

O. P. Hood thought that the difficulties mentioned could be met by changes in design and the employment of intelligent motormen. There are dangers inherent in the gasoline locomotives as there are in all mine appliances, in powder, for instance, but they should be guarded against and similarly gasoline locomotives should be operated with judgment and should not be discarded. The carburetors in the past have been built on a rugged type with simplicity as the watchword rather than efficient carburetion, and he advised that, in future, carburetors such as were used in automobiles should take the place of those now in mining use.

The third paper was on "Short Firing in Coal Mining by Electric Circuit from the Surface," by G. S. Rice and H. H. Clark. In the discussion, T. H. O'Brien, of the Stag Cañon Fuel Co., declared that the company was removing the electric switches placed at the mouth of every room, as they were not thought necessary now that the men do not charge their own holes. There is now no risk during the working hours, so the room switches are not necessary. Before, if a switch had been thrown on the heading, only the existence of the room switches would have prevented a general discharge of the holes, and a premature discharge from some other cause was always possible. To prevent this was the purpose of the room switch.

Misfires Are Due to Defective Wires

He said that misfires were almost always due to defective wires. Only two defective detonators had been found in several months. When misfires occur, the men are not allowed to return to work till the shots have been fired on the succeeding night.

A general discussion then followed on the Use of Electricity in Mines. In the afternoon trips were made to the U. S. Bureau of Mines and the oil and gas district of Oakdale, Penn. The Bureau of Mines display was varied and interesting. Mr. McElroy, with a team of students in first-aid, described to the guests in an extremely competent way just how the first-aid work his team was doing should be performed and why.

Once Again

There was a convincing thoroughness in both execution and description. Yet one matter roused question. Here was a patient with such a severe shock that to revive him the Shaefer method is adopted. He is recovered from death by the heroic efforts of the first-aid men and they then *sit* him up and begin to bandage his fingers and his head with picric-acid gauze.

There may be nothing wrong about that sitting up. We do not pretend to know. But we have learned that men are being demerited for it at American Mine-Safety Association and Red Cross meets. Why does the A. M. S. A. and the R. C. demerit if the Bureau of Mines persists in teaching that it is right. Or, *vice versa,* why does the Bureau teach it if it is wrong? And lastly, why do we so frequently have to mention this variation between the teaching of the Bureau and the action of the national associations? Surely some action should speedily be taken.

Coal Mining Institute of America

The winter meeting of the Coal Mining Institute of America will be held Dec. 8 and 9, 1914, at the Fort Pitt Hotel, Pittsburgh, Penn.

On Tuesday, Dec. 8, the morning will be devoted to the business session, the election of officers and the president's address; the afternoon will be filled by the question box discussion conducted by W. E. Fohl. The following questions are proposed: Is the longwall system applicable to the Pittsburgh seam of coal? What is a safe voltage for use in coal mines? Do compensation laws increase or decrease accidents in coal mines? What are the advantages and disadvantages in the use of portable electric lamps?

Following the Institute dinner, at 6:30 p.m. ($1.50 per plate), T. L. Lewis, of Columbus, Ohio, and H. H. Stoek, of Urbana, Ill., will deliver addresses on "Government Control with Relation to the Coal-Mining Industry."

On Wednesday, Dec. 9, the following papers will be read: "Foreign Coal Trade of the United States," by Dr. E. W. Parker, Washington, D. C.; "Last Stand of the Mine Roof," by R. D. Hall, New York City, N. Y.; "Personal Observations in Alaska," by Dr. W. R. Crane, State College, Penn.; and "Coal-Dust Experiments at Experimental Mine, Bruceton, Penn.," by L. M. Jones, U. S. Bureau of Mines. Charles L. Fay, secretary-treasurer.

Fourth Annual Banquet at Nanticoke

On the evening of Oct. 10 in the Broadway Armory at Nanticoke, Penn., was held the fourth annual banquet of the Nanticoke District Mining Institute. No less than 798 persons attended this banquet, and even then

not all who came could be accommodated. This was the greatest number of people ever banqueted in the building at one sitting, and there was consequently but scant room for the members of the Ladies Aid Society of the Methodist Episcopal Church, who served the diners, to move about. In spite of this handicap, however, both menu and service were excellent.

After the supper, John E. Kelley, president of the institute, reviewed the work of the organization during the past year. Mr. Kelley introduced the Hon. Peter A. O'Boyle as toastmaster, who spoke for several minutes, praising the work of the institute and encouraging its members.

J. G. Brecht, secretary of the State Board of Education, was next introduced. To him as well as to many others, the number of men present was a great surprise. Mr. Brecht's theme was the practical value of industrial education.

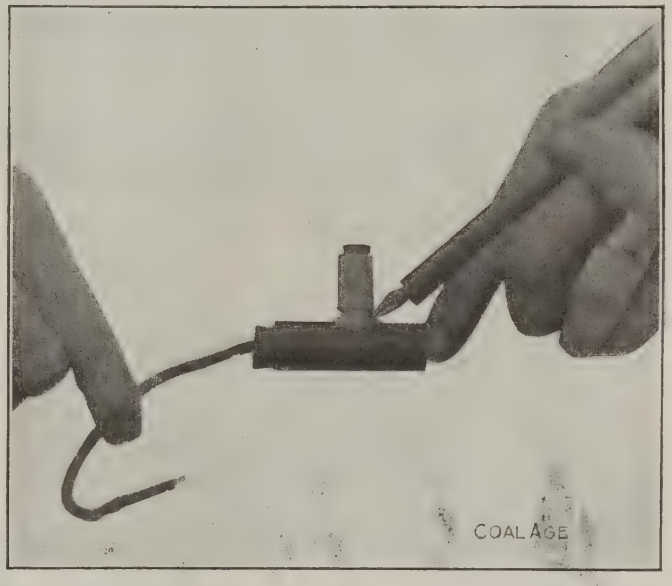
Franklin H. Ball, of Pittsburgh, and Superintendents Diffendofer and Dixon, the latter of Newport Township schools, each spoke briefly on the subject of the evening. Gen. C. B. Dougherty also spoke briefly but with good effect.

The idea of industrial education is by no means new, vocational night schools having been established in the anthracite region for some time. This movement is, however, constantly growing in popularity, and each succeeding year sees a larger number of men enrolled, a larger number that complete the work, and what is vastly more important, a larger number that are able to successfully apply the knowledge they have acquired through their studies.

A Chemical Fuse Lighter

By Barry Scobee*

For many years it has been recognized that there is grave danger in the blasting of coal, in mines generating gas and in dusty mines where the coal is highly inflammable. In order to avoid the wholesale destruction of life, in mines where the use of powder for blasting appeared to be an essential feature in the mining of the coal, the suggestion has been adopted of employing shotlighters to fire the shots after the miners have left the mine.



While the employment of shotfirers has greatly reduced the death list, in those mines, the sad fact remains that, in many states, particularly in Oklahoma and in Kansas, many shotfirers have sacrificed their lives in the performance of their duties. That the work of shotfiring is dangerous, under the best conditions and that this danger cannot be wholly eliminated under conditions that are less favorable is freely admitted. For this reason, any device or method for avoiding the danger incident to shotfiring is worthy of careful consideration.

Now, comes the suggestion of a chemical fuse lighter, for which the chief advantage claimed is the fact that by its use the fuse is ignited from 2 to 3 hr. after the necessary connection is made. The suggestion comes from John Dowd, a former druggist of Radley, Kan.

It is stated that this contrivance was used by the shotfirers, in shaft No. 8 of the Hamilton Coal Co., at Radley, for 13 nights in succession. The test was made on 25 shots each night, with varying results, during the first nine nights, most of the shots, however, being successfully fired each night. The last four nights every shot was fired except two; but the failure of these two shots to explode was found to be caused by other trouble and not due to any defect in the lighter. This showed that 98 out of 100 shots were successfully fired by the lighter, in the last four nights of the test.

Attention is drawn, in connection with this method of firing shots, to the danger of the powder becoming damp in the hole, before the fuse is ignited. This is particularly true where the drillhole is rough and jagged, and the paper wrappings of the charge are broken, thus permitting the dampness to reach the powder more readily. An important necessity, in employing this method, therefore, is the use of a drill that will bore a comparatively smooth hole.

The chemical fuse lighter is shown in the accompanying figure. It consists of a paper tube 2½ in. long,

Showing Construction of the Chemical Fuse Lighter

about the size of one's finger. One end of the tube is sealed with paraffin, while the other is closed with a common cork. Extending from one side of this tube, and at right angles to it, is a smaller celluloid tube having a cork in the top, like a bottle. At the junction of this small tube with the larger tube, as indicated by the pen point in the figure, is a thin diaphragm of celluloid, which closes the connection between the two tubes.

In the use of this device, the shotfirer pours about half a teaspoonful of sulphuric acid into the upright celluloid tube. It requires from 2 to 3 hr. for the acid to eat its way through the thin diaphragm and reach the combustible matter in the larger tube. This is fired by the action of the acid and in turn sets fire to the fuse that has been inserted through the cork in the end of the larger tube.

The device has not been manufactured, as yet, for the market; but it is claimed that it could be produced at a cost of from 2 to 3c. for each lighter. The idea is offered as a suggestion; and may lead to improvements that would reduce the cost of manufacture and make the device of greater utility in coal mining.

[This suggestion furnishes good material for discussion. Is the idea practicable?—Ed.]

*Pittsburg, Kan.

The Purchase of Coal on Specifications--IV

By F. R. Wadleigh*

SYNOPSIS—The fourth and concluding article of this series. This section is confined to abstracts from typical specifications for the purchase of coal. There is a wide range of selection including both domestic and foreign contracts.

At an informal meeting of the committee appointed by the American Society for Testing Materials, held in New York in May, 1914, a proposed form of "Specification and Contract for the Purchase of Coal for Use in Steam Power Plants" was submitted for discussion, a copy having been previously sent to each member for written comments. Below are given in detail:

1. Extracts from the minutes of the meeting, showing the consensus of opinion regarding such contracts and what they should include in the way of specifications.

2. Those parts of this contract referring especially to sampling and analysis.

It is thought that this information may be somewhat of a guide to those interested in the buying and selling of coal, since it gives the ideas of those who have had much practical experience in handling specification contracts, from every standpoint. It may also give a better understanding of the subject and result in the weeding out of unfair and impractical specifications.

It was decided to make no formal report this year, as the purchase of coal under specifications is in a development stage, and it was thought that the time had not yet arrived for the actual setting forth of a standard. To show that this method is still developing, the following questions were discussed:

1. Ash content and B.t.u. value have been and are widely used as factors for establishing the quality of coal bought under specifications, but the general conclusion has been reached that regular B.t.u. determinations on every sample are unnecessary, where all the coal comes from the same region and bed. In such case the B.t.u. value varies proportionately with the ash content, which, therefore, becomes a measure of heating value. When coal comes from different beds or regions, then B.t.u. values and analysis are of value.

2. Very few specifications in use make any mention of the clinkering qualities of coal, although this matter is of great importance and should be covered in all specifications. The fusing temperature of ash is used to measure this, but its method of determination should be further investigated, before definite recommendations can be made.

3. Moisture specification were also discussed. Neither the "as received" nor the "dry" basis have proved altogether satisfactory. Moisture in coal is variable; its exact determination in any shipment is difficult, because of uncontrollable losses, and its amount is largely accidental. To use the "dry-coal" basis may give inaccurate values when coals of different nature are compared. In fact a satisfactory way of handling the moisture question has not yet been evolved.

4. Alternate methods of analysis are not desirable; a standard specification should always specify one standard method. The question of weights was also discussed, but no conclusions arrived at.

EXTRACTS FROM PROPOSED SPECIFICATIONS AND CONTRACT FOR THE PURCHASE OF COAL FOR USE IN STEAM POWER PLANTS

VII—SAMPLING

11. **Company Privileged to Be Present.** The company shall have the privilege of having a representative present to witness the collection and preparation of the samples to be forwarded to the laboratory.

12. **Method.** The samples shall be collected and prepared in accordance with the method given in the appendix attached hereto as a part of these specifications and contract.

Note—As payment for coal delivered under this contract is to be based upon the quality as shown by analyses of representative samples, it is imperative that every sample be collected and prepared carefully and conscientiously and in strict accordance with the method agreed upon herein, for if the sampling is improperly done, a determined price, based on the analysis, would be in error, and it may be impossible or impracticable to take another sample; but if an analysis is in error, if desired, another analysis can easily be made of the original sample by a laboratory mutually satisfactory.

Gross samples of the quantities designated in the appendix must be taken whether the delivery consists of a few tons or several hundred tons, because of the following cardinal principle in sampling coal, which must be recognized and understood. The effect of the chance inclusion or exclusion of too many or too few pieces of slate or other impurities in what, or from what, would otherwise have been a representative sample, will cause the analysis to be in error accordingly, regardless of the tonnage sampled. For example, the chance inclusion or exclusion of, say, 10 lb. too much or too little of impurities in or from an otherwise representative sample of 100 lb., would cause the analysis to show an error in ash content and in heat units of approximately 10 per cent., whereas for a 1000-lb. sample, the effect would be approximately only 1 per cent. the effect being the same whether the sample was collected from, say, a one-ton delivery or from a delivery of several hundred tons.

VIII—ANALYSES

13. **Laboratory and Method.** The samples shall be immediately forwarded to the ..... laboratory, and they shall be analyzed and tested in accordance with the method recommended by the American Chemical Society and by the use of a bomb calorimeter. The expense of such analyses and tests shall be borne by the consumer. The results, together with the corrected price per ton, shall be reported promptly to the company.

14. **Settlement of Disputed Results.** Should the company question the reported results—except the moisture results, which are to be considered as final—the consumer shall, if requested by the company within five days after its receipt of such report, send the third sealed part or parts of the sample or samples held by the consumer, as provided for in paragraph 6 of the appendix, to the following laboratory, mutually agreed upon: .....

If the results in question represent the average of the analyses of two or more different samples, then the laboratory agreed upon shall analyze each sample separately and average the analyses, giving each analysis a weight proportionate to the tonnage that it represents. The results obtained by the laboratory agreed upon shall be considered as final. In case reports reported by the laboratory agreed upon shall be within 150 B.t.u., or 1 per cent. ash, or 2 per cent. volatile matter, or 0.25 per cent. sulphur of the questioned factor or factors, then the charge of the said laboratory shall be borne by the company, but if the disputed factor or factors shall be found to vary by more than these margins, then the charge shall be borne by the consumer.

IX—DESCRIPTION OF COAL DESIRED BY THE CONSUMER

15. **Kind and Quality.** The coal must be a good (coking, noncoking) coal, free from excessive dust, and must approxi-

*Consulting engineer, 426 Real Estate Trust Bldg., Philadelphia, Penn.

mate in quality the following proximate analysis and heating value:

Moisture in "delivered coal" ..... per cent.
Volatile matter in "dry coal" ..... per cent.
Ash in "dry coal" ..... per cent.
Sulphur in "dry coal" ..... per cent.
British thermal units in "dry coal" .....

16. **Size of Coal.** .....

X—DESCRIPTION OF COAL OFFERED BY THE COMPANY

17. **Price Per Ton.** The company hereby agrees to furnish coal of the character and quality specified in paragraphs 18 and 19 below, and from the mine or mines specified in paragraph 20 below, in accordance with all of the conditions and requirements of this contract, at $.... per ton of 2240 (or 2000) lb.

18. **Size.** Coal will be furnished of the size specified in paragraph 16, under Sect. IX, "Description of Coal Desired by the Consumer."

19. **Analysis Guaranteed.** The coal herein specified shall show the following analysis:

Moisture in the coal "as received" ..... per cent.
Volatile matter in "dry coal" ..... per cent.
Ash in "dry coal" ..... per cent.
Sulphur in "dry coal" ..... per cent.
British thermal units per pound in "dry coal"

20. **Source.** The source of the coal herein specified shall be as outlined below:

Name of mine or mines .....
.....
Location of mine or mines (town, county and state)
.....
Name or other designation of coal bed .....
.....
Name of operator of mine or mines .....
.....
Commercial name of coal .....
Railroad on which mine or mines are located .....

Note—Bids not supplying the foregoing information may be considered informal and may be rejected.

Coal of the description and analysis above specified is herein known as coal of the contract grade. Bidders are cautioned against specifying higher standards than can be maintained, for to do so will result in deductions in price and may result in the rejection of delivered coal or the cancellation of the contract. In this connection, it should be recognized that the small "mine samples" usually indicate a coal of higher economic value than that actually delivered in carload lots, because of the care taken to separate extraneous matter from the coal in the "mine samples."

VIII—PRICE AND PAYMENT

28. **Determination of Price.** The consumer hereby agrees to pay the company, during the calendar month following delivery, for each ton of 2240 (or 2200) lb. of coal delivered and accepted in accordance with all the terms of this contract, the price per ton determined by taking the analyses of the samples, or the average of the analyses, if more than one, upon the basis of the price herein named in paragraph 17 above, adjusted as follows for variations in heating value, ash content and moisture content from the standard guaranteed herein, in paragraph 19 above, by the company:

(a) **Heat Unit Adjustment.** When the coal is considered on a "dry coal" basis, no adjustment in price shall be made for variations of 2 per cent. or less in the number of British thermal units from the guaranteed standard. When the variation in heat units exceeds 2 per cent. of the guaranteed standard, the adjustment shall be proportional and shall be determined by the following formula:

$$\frac{\text{B.t.u. delivered coal ("dry coal" basis)}}{\text{B.t.u. ("dry coal" basis) specified in contract}} \times \text{bid price} = \text{price resulting for B.t.u. variation from the standard.}$$

The adjusted price shall be figured to the nearest tenth of a cent.

As an example, for coal delivered on a contract guaranteeing 14,000 B.t.u. on a "dry coal" basis at a bid price of $3 per ton that shows, by calorific test, results varying between 13,720 and 14,280 B.t.u., there would be no price adjustment. If, however, by way of further example, the delivered coal should show by calorific test 14,300 B.t.u. on a "dry coal" basis, the price for this variation from the contract guaranty would be, by substitution in the formula.

$$\frac{14{,}300}{14{,}000} \times \$3 = \$3.064$$

(b) **Ash Adjustment.** No adjustment in price shall be made for variations of 2 per cent. or less below or above the guaranteed percentage of ash on the "dry coal" basis. When the variation exceeds 2 per cent., the adjustment in price shall be determined as follows:

The difference between the ash content by analysis and the ash content guaranteed shall be divided by 2, and the quotient shall be multiplied by the bid price, and the result shall be added to, or deducted from, the price adjusted for British thermal units, or the bid price if there is no adjustment for British thermal units, according to whether the ash content by analysis is below or above the percentage guaranteed. The adjustment for ash content shall be figured to the nearest tenth of a cent.

As an example of the method of determining the adjustment in cents per ton for coal containing ash varying by more than 2 per cent. from the standard, a coal may be considered that has been delivered under a contract guaranteeing 10 per cent. ash at a bid price of $3 per ton. If the coal shows by analysis an ash content of 13.26 per cent., the adjustment in price would be determined as follows:

The difference between 10 and 13.26, which is 3.26, would be divided by 2, and the quotient of 1.63 multiplied by $3, resulting in an adjustment of 4.9c. per ton, which in this case would be a deduction.

(c) **Moisture Adjustment.** The price shall be further adjusted for moisture content in excess of the amount guaranteed by the contractor, the adjustment being determined by multiplying the price bid by the percentage of moisture in excess of the amount guaranteed. The adjustment, which is a deduction, shall be figured to the nearest tenth of a cent.

As an example, a coal may be considered that has been delivered under a contract guaranteeing a moisture content of 3 per cent., the price bid being $3 per ton. If, on analysis, the coal shows 4.58 per cent. moisture, the bid price should be multiplied by 1.58 (representing excess moisture), giving 4.7c. as the deduction per ton.

APPENDIX

METHOD OF SAMPLING COAL DELIVERIES

To be attached to and to become a part of the Specifications and Contract issued by ..... for the purchase of coal for the period commencing ..... and ending .....

1. **During Unloading.** The coal shall be sampled when it is being unloaded from railroad cars, ships, barges or wagons, or when discharged from the company's supply bins, or from industrial railway cars, or grab buckets, or from the coal-conveying equipment at the power plant, as the case may be and as may be mutually agreed upon.

2. **Size of Increments.** To collect samples, a shovel or specially designed tool or mechanical means shall be used for taking portions of increasements of 10 to 30 lb. of coal. For slack or small sizes of anthracite, increasements as small as 5 to 10 lb. may be taken. The size of the increasement shall depend on the size and weight of the largest pieces of coal and impurities.

3. **Collection of Gross Sample.** The increments shall be regularly and systematically collected, so that the entire delivery will be represented proportionately in the gross sample. The frequency of collecting the increments shall be regulated so that a gross sample of not less than 1000 lb. shall be collected. If the coal contains an abnormal amount of impurities, such as slate, and if the pieces of such impurities are very large, gross samples of 1500 lb. or more, as may be mutually agreed upon, shall be collected. For slack coal, and for small sizes of anthracite, if the impurities do not exist in abnormal quantities or in pieces larger than three-quarters of an inch, a gross sample of approximately 500 lb. shall be considered sufficient. The gross sample shall contain the same proportion of lump coal, fine coal and impurities as is contained in the coal delivered. As the increments are collected, they shall be deposited in a waterproof receptacle having a tight-fitting lid and provided with a lock.

4. **Quantity Represented.** A gross sample of the size specified above shall be taken for each 500 tons or less.

5. **Preparation.** After the gross sample shall have been collected, it shall be systematically crushed, mixed and reduced in quantity to convenient size for transmittal to the laboratory. The crushing shall be done by a mechanical crusher or by hand with a tamper on a smooth and solid floor, or, in the absence of a smooth, tight floor, the crushing shall be done on a heavy canvas, to prevent the accidental admixture of any foreign matter. The mixing and reduction shall be done by hand with a shovel, or mechanically by means of riffles or sampling machines.

6. **Hand Preparation.** When prepared by hand, the pieces of coal and impurities shall be crushed to the approximate size indicated in the table below before each reduction:

Weight of sample to be divided	Size to which coal and impurities should be broken before each division.
1000 lb. or more	1 in.
500 lb.	¾ in.
250 lb.	½ in.
125 lb.	⅜ in.
60 lb.	¼ in.

The 60-lb. sample shall then be reduced by quartering, or by the use of riffles or sampling machines, to about 15 lb. This 15-lb. part shall be thoroughly mixed and divided into three equal parts. Each part shall be placed in an air-tight glass jar or metal can which shall bear an unbroken seal. One of the samples shall be forwarded to the ..... laboratory, named in paragraph 15 of the contract proper, one shall be turned over to the company, and the third shall be held by the consumer. Should the analysis be questioned by the company, the third sample shall be forwarded to the laboratory mutually agreed upon and named in paragraph 14 of the contract proper.

7. **Mixing and Reduction by "Alternate Shovelfuls."** After each crushing, the sample, if prepared by hand, shall be thoroughly mixed before reduction in quantity, the procedure being as follows:

The crushed coal shall be shoveled into a conical pile. A new long pile shall then be formed, the shoveler taking a shovelful at a time and spreading the coal out in a straight line (8 to 10 ft. long for a shovel holding about 15 lb.). Each new shovelful shall be spread over the top of the preceding one, the shoveler beginning at one end of the pile for the first shovelful and at the other end for the succeeding shovelful, and so on, the pile being occasionally flattened with the flat side of the shovel, until all the coal has been formed into one long pile. The shoveler, by walking around the long pile, advancing a distance equal to the width of the shovel, and systematically taking shovelfuls, and shoveling the coal to one side, alternate shovelfuls being discarded, shall cause the sample to be halved in quantity.

8. **Mixing and Reduction by "Quartering."** The above "long-pile" and "alternate-shovel" method of mixing and reducing the sample shall be followed with samples of 125 to 250 lb. or more. Samples smaller shall be mixed on a canvas about 8 ft. square by raising first one end of the canvas and then the other, the sample being thereby rolled back and forth. After the sample shall have been thoroughly mixed in this manner, the four corners of the canvas shall be gathered up, and the sample shall be formed in a conical pile and reduced in quantity by quartering, as follows:

The cone shall be flattened, its apex being pressed down with the back side of the shovel, or with a board, so that each quarter contains the material originally in it. The flattened mass, which shall be of uniform thickness and diameter, shall then be marked into quarters, with a board held edgewise, or with a piece of sheet iron, along two lines that intersect at right angles directly under the apex of the original cone. The diagonally opposite quarters shall then be shoveled away and discarded and the space that they occupied brushed clean. The coal remaining shall be successively crushed, mixed, coned and quartered on the canvas until two opposite quarters shall equal the quantity (approximately 15 lb.) required to fill the three containers mentioned in paragraph 5 above.

9. **Progressive Crushing of Increments.** Whenever the different increments of samples are collected throughout some considerable period of time, each increment, or an accumulation of a number of increments, may be crushed as soon as taken and the pieces of coal and impurities may be broken sufficiently small to permit two or three, or more, reductions of the total accumulated sample before further crushing shall be necessary.

10. **Extended Deliveries.** If deliveries extend over any considerable period, what would otherwise be a gross sample may be worked down in successive stages to samples of a size suitable for transmittal to the laboratory, and these samples, which shall be approximately equal in quantity, and shall represent the several equal parts of a delivery, may be analyzed and the several analyses averaged, or the several samples may later be mixed at the delivery point or in the laboratory and reduced to one sample, one analysis being made.

11. **Special Moisture Sample.** In the reduction of the gross sample to the sample for transmittal to the laboratory, the gross sample will unavoidably lose moisture. To determine the moisture content in the coal delivered, a separate special moisture sample must be taken.

12. **Collection of Moisture Sample.** The special moisture sample shall contain approximately 100 lb., and shall be accumulated by placing in a waterproof receptacle, with a tight-fitting and waterproof lid, small parts of the freshly taken increments of the gross sample, or they may be collected separately and independently of the gross sample. The accumulated moisture sample shall be immediately crushed and reduced mechanically or by hand to about a 5-lb. quantity, which shall be immediately placed in a container and sealed air tight and forwarded to the laboratory. If prepared by hand, it shall be rapidly crushed so that no piece of coal or impurities are larger than one-half inch, and it shall be rapidly reduced by the "quartering" method on a canvas to the 5-lb. quantity.

13. **Moisture Samples Discretionary.** The collection of special moisture samples shall be discretionary with the consumer.

14. **Moisture Samples May Represent Any Part of Delivery.**

15. **Sampling of 50 Tons or Less Discretionary.** When orders are issued for 50 tons or less, sampling shall be discretionary with the consumer, and if samples are not taken, the bid price per ton shall be paid, but all coal so delivered may be rejected if it shall give unsatisfactory results because of excessive clinkering, or excessive ash-pit refuse, or a prohibitive amount of smoke, or any other cause that makes it an undesirable fuel.

There are many other forms of specifications in use in this country. Probably the one on which most of the coal has been bought is that used by the U. S. Government, prepared by the Bureau of Mines under which, for the fiscal year of 1913, 1,374,000 tons of coal were bought. These specifications are given in full in Bulletin 63, by George S. Pope, engineer in charge of the Inspection of Government Coal Purchases. Another type of specifications originally prepared by the Fuel Engineering Co., of Chicago, is much used, while nearly all of the large electric-light and power companies and state and municipal power plants have their own forms. As the various types are now quite well known and have been much discussed in different publications, they will not be given here; none of them are entirely satisfactory to the sellers of coal and some are absolutely unfair.

Some of the technical features of specifications used abroad are of interest, and may show different viewpoints of the whole matter, from which we may get new ideas. Extracts are therefore given below from some typical foreign specifications.

ASSOCIATED MUNICIPAL ENGINEERS, LONDON
(Extracts From Specifications)

Tenderers are requested to tender for coal to be supplied in accordance with either or both of the following alternative specifications: Specification (A) For coal of a particular description, hereinafter described as "Named Coal;" Specification (B) For coal guaranteed to have definite physical qualities as a fuel for steam-raising purposes, hereinafter described as "Guaranteed Coal." In the specification of "Named Coal," the tenderer is required to set out in the tenderer's details: (1) The name of the pit from which the coal will be delivered; (2) The description applied to the particular class of coal from the colliery: (3) Size as specified by the colliery. In the specification of "Guaranteed Coal," the tenderer is required to set out in his details the classes of coal for which he is tendering, corresponding with the classes referred to in the table of standards.

TESTING

A. A representative sample shall be taken on delivery from each or any consignment and shall be divided and sealed in three air-tight vessels; the contractor shall be at liberty to be represented when the sample is taken and shall be entitled to one portion thereof. The contractor shall have no opportunity at a later date of objecting to the manner in which the coal has been sampled.

B. Samples taken in the manner herein defined shall be taken from each consignment and tested by the purchaser, or in the event of dispute, by a competent expert, who shall be approved from time to time by the purchaser, and whose fees shall be paid by the contractor if the purchaser's test is confirmed. The tenderer is invited to set out in the tenderer's details the names of three experts either of whom he is agreeable shall be employed.

BONUS AND PENALTY

No variation of the contract price shall be made for any variation from the standard not exceeding one-twentieth, up or down of the figures given in the table of standards.

A. If the calorific value exceeds the standard value in British thermal units per pound, the price per ton shall be increased in the same percentage ratio as the increase in the calorific value.

B. If the calorific value be less than the standard value in thermal units per pound, the price per ton shall be de-

creased in the same percentage ratio as the decrease in calorific value, provided always that the purchaser shall have the right to reject the whole consignment if the calorific value be more than 7½ per cent. below the standard.

C. If the moisture be less than the standard percentage by weight, the weight of coal to be paid for shall be increased beyond the quantity actually weighed out by a percentage equal to the percentage decrease of moisture.

D. If the moisture exceeds the standard percentage by weight, the weight of coal to be paid for shall be decreased below the quantity actually weighed out by a percentage equal to the percentage increase of moisture. Provided always, that the purchasers shall have the right to reject the whole consignment if the total moisture exceeds one and a half times the moisture given in the table of standards.

E. If the percentage of small coal be less than the standard percentage by weight, the weight of the coal to be paid for shall be increased beyond the quantity weighed out by a percentage equal to one-quarter of the percentage decrease of small coal, percentages to be taken on the bulk and not on the standard.

F. If the percentage of small coal exceeds the standard percentage by weight, the weight of the coal to be paid for shall be decreased below the quantity actually weighed out by a percentage equal to one-quarter of the percentage increase of small coal, provided always that the purchasers shall have the right to reject the whole of the consignment if the proportion of small coal exceeds 25 per cent. by weight, percentages to be taken on the bulk and not on the standard.

TABLE OF STANDARDS TO BE APPLIED IN CONNECTION WITH GUARANTEED COALS

	B.t.u.	Moisture Per Cent.	Small Coal—Through Inch Square Mesh	Small Coal—Per Cent.
A. Bituminous Durham and Yorkshire.				
1. Washed double nuts	13,250	8	½	15
2. Washed single nuts	13,000	9	⅜	17½
3. Washed peas	12,750	10	¼	20
B. Bituminous Scotch Washed Coals.				
1. Washed double nuts	12,750	10	½	15
2. Washed single nuts	12,500	11	⅜	20
3. Washed peas	12,000	13	5/16	20
C. Semi-Bituminous and Pseudo-Anthracite. Welsh Washed Coals.				
1. Washed large nuts	14,300	5	½	15
2. Washed small nuts	13,900	6	⅜	20
3. Washed peas	13,350	6	5/16	20
D. Bituminous Durham and Yorkshire Dry Screened Coals.				
1. Double nuts	12,750	5	½	17½
2. Single nuts	12,500	6	⅜	25
3. Peas	12,250	6	¼	25
E. Bituminous Derbyshire and Nottinghamshire Dry Screened Coals.				
1. Double nuts	12,250	9	½	15
2. Double screened small nuts	12,000	9	⅜	20
3. Pea nuts	11,500	10	5/16	20
F. Bituminous Leicester-Warwick and South Staffordshire Dry Screened Coals.				
1. Double nuts	12,000	10	½	15
2. Double screened small nuts	11,750	10	⅜	20
3. Pea nuts	11,250	12	5/16	20

British thermal units shall be ascertained on coal dried at 220 deg. F. for an hour by means of a Mahler bomb calorimeter.

Moisture shall be represented by the total loss in weight of the coal as delivered after air drying and exposing to a temperature of 220 deg. F. for one hour.

The percentage of sulphur shall be based on the analysis of the coal "as received," and must not exceed 2 per cent.

The sieves used for determining the percentage of "small" shall be of square mesh, with openings in the clear to the sizes given.

It will be noticed that the table gives no figures for ash, this factor being sufficiently covered, it is considered, by the calorific value. This is entirely contrary to the practice here, and is not, we consider, in the right direction; it would be better to use the ash basis and leave out the B.t.u. value.

It is true that increase or decrease in the B.t.u. value generally means lower or higher ash percentage, when applied to the same kind of coal, but there are other points in which ash is a factor besides the mere heating value.

ITALIAN STATE RAILWAYS
(Extracts From Specifications)

Origin of Coal—The coal to be obtained from good seams in the district of .....

The origin of the coal must be guaranteed during the whole contract by certificates from the mines and other documents that the railroad administration requires.

The administration reserves the right to ascertain the origin at the mine by its own agent, to whom the shipper must give all the proofs necessary.

Quality of Coal—Large coal should be divided from the slate or other foreign materials, and should be of such a quality suitable for special use in locomotives.

In order to ascertain this, the coal will be tried on the locomotives and should be capable of producing abundant steam. After combustion, the ash should not obstruct or cling to the grate bars.

In case it should be found that the coal does not correspond exactly to the foregoing conditions, the administration of the railroads will have the right to cancel further shipment from the mine supplying such unapproved coal.

The large coal should not contain more than 20 per cent. of small when unloading it in the harbor of the purchaser. The administration, in order to ascertain the percentage, will screen the coal when unloading from the ship. The percentage of small will be ascertained on the ground while passing the coal slowly and in small quantities over a screen of the dimensions of 2 by 1 m. with the bars 12 mm. apart and placed in an inclined position of 45 deg.

The test by screening will take a quantity of the coal corresponding to about 2 per cent. of the unloading. Should the consignment be unloaded in different ways, namely, directly from the ship to cars on the wharf, or into barges, the quantity used for the screening test will be taken proportionately from each of the different ways of discharging.

For the coal that is directly taken from the ship to the cars, one sample for test will be taken from one carload per day. For the coal that is taken directly from the ship to the wharf, there will be taken at the time of unloading, a number of baskets of coal, and this coal will form a small heap which will be screened and the percentage obtained. For the coal that is loaded into barges, a certain number of baskets will be taken as above.

Finally, upon the unloading of the steamer, there will be determined the mean percentage of smalls contained in the whole shipment. This report will be made from the coal directly unloaded from the ship. The quantity of smalls exceeding their allowances as above will be considered as small and paid $1.44 per ton less than the price agreed upon.

The railroad company reserves the right to change the full consignments of the coal whenever the coal should show excessive friability.

Heat Units—The mean heat power of the large coal will be 7750 calories and will be determined by the Thompson calorimeter. In case of decrease of calories, there will be for every English ton a penalty of 0.1c. ($^5/_{1000}$th) for every missing calorie.

Ashes—The mean ash from large coal should not exceed 5 per cent.; in case of an excess, the penalty of 8c. ($^{10}/_{100}$ths) will be charged for each English ton, and for the hundredth unit, the fraction of the unit will be considered proportionately.

Sulphur—The quantity of sulphur should not exceed 1.10 per cent.; in case of excess, the company will have the right of changing the origin of the coal.

Volatile Matter—The volatile matter will range between the minimum limit of 14 per cent. to the maximum of 25 per cent., deducting the humidity.

Humidity—Coal should not contain more than 0.9 per cent. of water of composition. The administration will have the right to carry out the conditions of this clause pertaining to the samples. In each taking, they will choose a sample from one or more baskets taken from each pile, in equal quantities from the small and large, and these should weigh about 20 kilos. This coal will be passed into receptacles of thin metal, and after mixing, a sample will be taken therefrom and passed into a glass receptacle with a stopper polished and paraffined, with the date of taking, and will be forwarded to the chemical laboratory of the administration and tested at a temperature of 100 deg. C.

The means of the results obtained from the samples taken every day will give the humidity, and if this should be greater than 0.9 per cent., the difference will be applied to the quantity of the unloaded coal on the day to which the test refers, allowing for the smaller weight.

Determination of Calories, Ash, Sulphur and Volatile Matter—For the determination of the requirements mentioned in Article 4, there will be taken from every vessel at the port of unloading, 10 samples of coal 10 kilos in weight, each to be taken at an equal interval during the unloading.

Each of these samples will be taken from the barges or from the wharf, according to the manner of unloading, and

should be taken from the small coal. Every sample will be placed in a bag, with the seal of the administration, and have a tag indicating the number of the contract, the name of the boat, date of delivery and the firm of the agents of the shippers. The sample will remain in the custody of the administration.

After the verification of the seals at the laboratory, the 10 samples will be opened and the coal contained in them will be collected together and ground well and mixed in such a manner as to form a homogeneous mass. From this will be taken 1.50 kilos of coal, which, after having been ground again and mixed, will be divided into three equal parts in such a manner as to form three samples of ½ kilo each. These samples will be sealed and labeled and two will be retained by the chemical laboratory of the administration, and one will be remitted to the shipper. Of the two samples remaining in the chemical laboratory of the administration, one will serve for test and for chemical analysis and the other will be held in reserve subject to the demand of the shipper. Second analysis will only be called for in case of confirmation being required.

The consignor should assist at the making of the analysis. The results of the analysis will in no case be protested.

Penalty—The analysis will be made separately for the loading of each ship, and the following penalties will be made unless the shipment is in accordance with Article 4: (a) As regards the determination of ashes and calories; (b) As regards the humidity. To complete the shipment it will be necessary to obtain the mean results of percentage of ash and amount of calories for all samples, and this mean will be decided as regards the payment and the acceptance of the shipment.

The penalty of excess of percentage of ash and deficiency in calories will never be applied simultaneously, but only the greater of the two will be used.

STOCKHOLM ELECTRICITY WORKS, SWEDEN
(Extracts From Specification)

Coal supplied under this proposal must be suitable for automatic chain-grate stokers with natural draught (Babcock & Wilcox type). The percentage of volatile matter should amount to between 28 to 35 per cent., and the percentage of ash not exceed 18 to 20 per cent. All percentages figured on the basis of dry coal.

Coal furnished under this proposal should preferably be suitable for direct use without crushing, such as rough smalls, peas or pearls, nuts or beans, etc., but proposals made on the basis of large coals will also be considered.

The proposal should contain the following data: (a) The name by which the coal offered is generally known in the market. (b) The name of the coal field and the colliery or collieries where the coals are mined. (c) The size and kind of screen over which and through which the coal has passed when screened. (d) Approximate percentage of dust and fine coal (all coal which will pass through a ⅛-in. hole). (e) The percentage of volatile matters in the dry coal (complete analysis should if possible be submitted). (f) Character of the clinkers formed by the combustion of the coals. (g) Approximate weight of the coal per cubic centimeter.

If the actual heating value of the coal delivered should differ from the established standard, the price per ton will be altered in direct proportion to the difference in heating value. For all coal which, by analysis, contains less ash than the standard established in the tender, a premium of halfpenny per ton for each whole percentage less ash will be paid. An increase in the ash content of 2 per cent. over the standard established by the contractor will be tolerated without exacting a penalty. When such excess exceeds 2 per cent. above the standard, deductions will be made from the price paid per ton in accordance with the following table.

(Note—This ash table is the same as used by the U. S. Bureau of Mines.)

If the percentage of moisture should differ from the standard, the price per ton is altered in inverse proportion. For example, if the coal contains 2 per cent. more or less moisture than the standard, the price will be decreased 2 per cent. accordingly.

To get a fair average of the coal delivered, samples should be taken all the time the ship is unloading in order to obtain samples from all parts of the cargo. The sample taken shall not be less than 600 lb. The gross sample will be pulverized as rapidly as possible, mixed thoroughly and divided into four equal parts. Opposite quarters will be thrown out and the remaining portions thoroughly mixed and again quartered, throwing out opposite quarters as before. This process will be continued until the final sample is reduced to such amount as to be suitable for test.

This sample will be analyzed and tested (using a bomb calorimeter) by the Kungl Tekniska Hogskolans Materialprefningsanstalt (the testing department of the Royal Technical Institute in Stockholm). A copy of the result will be mailed to the contractor on the completion thereof. On this test will be based the corrections to be made on the standard price. The right is reserved to the contractor or his representative to be present and witness the sampling and preparation of the final sample. The cost of the test to be paid by the purchaser.

LONDON COUNTY COUNCIL POWER STATION
(Extracts From Specification)

The specified standards are:

Calorific value	12,500 B.t.u.
Small (passing through ⅜-in. mesh sieve)	20% by measurement
Moisture	10% by weight

The calorific value and moisture are measured by the county council chemist on samples taken from every 100 tons brought over the pier head, the calorific value being determined by a Mahler bomb calorimeter on samples dried at 100 deg. C. Moisture is determined on a weighed portion of the sample taken from an air-tight tin.

Small coal is ascertained on the pier on a sample of about 50 lb. in weight, taken at the option of the council, either from the hold or from the quantity unloaded from the grabs.

If the quality of the coal in any cargo, as ascertained by the samples tested, be found different as regards calorific value, moisture or small from the above standards, the price paid to the contractor is varied as follows:

(a) If the calorific value exceeds 12,500 B.t.u., the price per ton is increased in the same percentage ratio as the increase in calorific value.

(b) If the calorific value is less than 12,500 B.t.u., the price is decreased in the same percentage ratio. The council, however, has the right to reject the whole of the cargo if the calorific value be less than 10,500 B.t.u.

(c) If the moisture is less than 10 per cent. by weight, the quantity of coal to be paid for is increased beyond the quantity weighed in by a percentage equal to the percentage decrease of moisture.

(d) If the moisture exceeds 10 per cent. by weight, the weight of coal to be paid for is decreased below the quantity weighed in by a percentage equal to the percentage increase in moisture. The council, however, has the right to reject the whole cargo if the moisture exceeds 13 per cent.

(e) If the proportion of small be less than 20 per cent. by weight, the weight of coal to be paid for is increased beyond the quantity actually weighed in by a percentage equal to a quarter of the percentage decrease of small coal.

(f) If the proportion of small coal exceeds 20 per cent. by weight, the weight of coal to be paid for is decreased below the quantity actually weighed in by a percentage equal to a quarter of the percentage increase of small coal. The council, however, has the right to reject the whole cargo if the proportion of small coal exceeds 25 per cent. by weight.

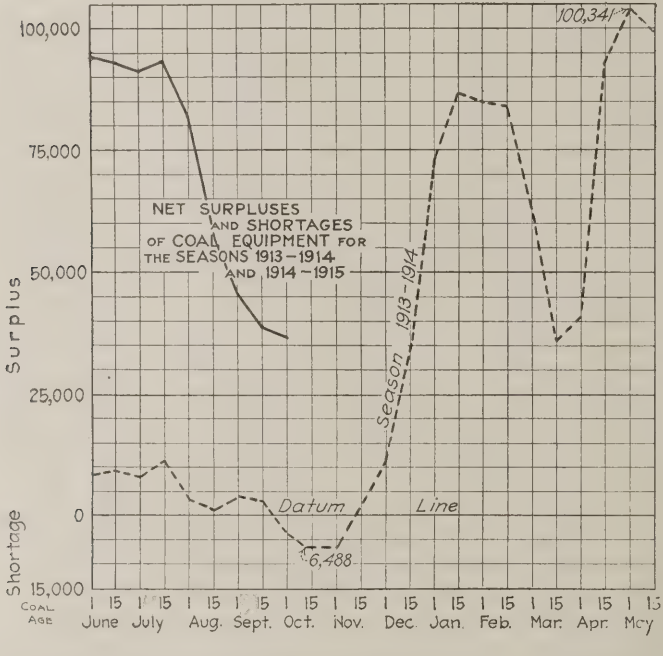
As a general conclusion, it is believed by many chemists, engineers and others, that after the buyer of steam coal has decided on the description of coal he desires and what is best adapted to his use, there are only two items necessary, as regards analysis, in making up specifications, that is, the percentage of ash and the fusing temperature of the ash.

A standard percentage of ash of a given kind of coal (field or seam) insures a standard B.t.u. value; any change in ash percentage makes a corresponding change in B.t.u. value. The right ash-fusing temperature means no clinkers and good combustion results, if the coal is handled properly.

Where smoke laws are to be observed, it may be necessary to specify also a maximum volatile content of the coal, although even here it would generally be advisable and economical in the end to alter furnace and boiler conditions, so that higher volatile, cheaper (usually) coals could be used.

Simplicity, equity and practicability, should be the characteristics of all specifications for the purchase of coals.

*



Never neglect for a moment the early signs of a fire in the underground workings of a mine. Either deal with it yourself immediately, or report it straight away to your superior.

An Analysis of the Coal-Car Situation

Compiled by A. T. Shurick

SYNOPSIS—In conformance with our past custom we present herewith a brief summary of the car-supply outlook for the coming winter. With the kind assistance and hearty coöperation of many of the leading railroad officials we are fortunate in being able to give an accurate and concise review of the actual physical condition of the leading coal roads. The current outlook is notably more favorable than usual but still replete with grave latent possibilities, due to the generally weakened financial condition of the transportation companies.

There has probably been less anxiety expressed over the possibilities of a car shortage the coming fall and winter than for a number of years. Ordinarily this season of the year occasions a great deal of concern to the operating companies. It is at this time that the consumers are reminded by occasional cold snaps, of the necessity

Curves Show Fluctuations in the Car Supply

of laying in their winter stocks, while at the same time, the resources of the railroads are being strained to the limit handling the crops; in addition, the situation is often further aggravated by more or less inclement weather which seriously interrupts the running schedules.

Because of the generally depressed conditions throughout the country, the freight movement on the railroads has seldom been lighter, and the different systems are expressing every confidence in their ability to handle the situation this year without any trouble whatever. On the other hand, all must agree that there are still certain unknown factors in the problem, viz., the extent of the demand and the weather. If the current market conditions may be taken as any criterion of the outlook for the winter, it is manifest that the demand for coal is not liable to be of sufficient proportions to seriously burden the railroads, but on the other hand those familiar with the idiosyncrasies of the coal market are well aware of its liability to experience a direct reversal of form almost over night. As to the weather conditions, even with a comparatively restricted movement, it is possible for the situation to be so adverse in this respect as to prove a serious factor.

There is also this further consideration, the great importance of which must be conceded by all, and that is, the exceedingly weakened financial condition of the railroads. While the publicity campaign conducted by the railroads, in their attempt to secure a general horizontal advance in freight rates, no doubt somewhat exaggerated conditions in this respect, it is obvious, from a perusal of their various financial statements that new construction, repairs and maintenance have all been curtailed to an irreducible minimum. It is inevitable, therefore, that the actual physical condition of the railroad systems of the country is considerably below normal, and careful students of the situation are agreed that the combination of any abnormally severe weather, together with a heavy freight movement, would be accompanied with grave possibilities of a severe collapse in our transportation facilities.

The Kanawha & Michigan Ry.

(By President F. B. Sheldon.)

Since the close of the year this company has added to its motive power seven heavy consolidation freight locomotives received in July, and 1160 steel coal cars of 50 tons capacity, received in July and August, the latter adding 30 per cent. to the capacity of its coal-car equipment, which now amounts to 6000 cars.

During the past year alignment and grades were changed for a distance of one mile on the Ohio Division, excessive curvature being reduced to three degrees or less, and grades in both directions entirely eliminated. Terminal yards were increased during the year by the addition of three and one-half miles of sidings, while 17 passing tracks on the West Virginia Division, involving three additional miles of track, were lengthened to the standard of 4000 ft. to accommodate longer freight trains. Some 19 miles of main track were relaid with 90-lb. steel rail, and the entire length of the main track between the northern terminus at Corning, Ohio, and the southern terminus at Gauley Bridge, W. Va., is now laid with rails of that weight. The road and its equipment are in excellent condition for the winter, and the recent large increase in its coal-carrying equipment assures a good car supply.

The Hocking Valley Ry.

(By Vice-President M. J. Caples.)

During the past summer the Hocking Valley Ry. has completed and put into use a modern coal-handling plant on the east side of the Maumee River at Toledo, Ohio. This plant is capable of loading aboard vessels at least 160,000 tons of coal per day of 24 hr., when worked to full capacity.

During the summer just past, the road has received 1000 additional 57½-ton coal cars. Our coal-car capac-

ity at the present time is 516,450 tons, compared with 417,020 tons at this time last year. The tractive power of locomotives now is 4,938,920 lb. as compared with 4,574,120 lb. last year.

The Hocking Valley, with its present trackage facilities, can handle 50 per cent. more business south of Columbus than it handled last year and 25 per cent. more business north of Columbus. There is no probability but that we will not be able to supply all of the coal cars required and handle all of the business offered us promptly.

The Chesapeake & Ohio Ry.

(By E. P. Goodwin, Superintendent Transportation.)

The consensus of opinion, as far as I have been able to learn, is equally balanced as to prospective increase or decrease of coal loading, under the conditions brought about by the European war. The C. & O. Ry. has just gone through four months of the heaviest loading in its history, and I personally feel that the demand for coal will be good, and anticipate that our car supply will be adequate to meet it.

The road has increased its coal-car equipment 15.34 per cent. in the past year, and has greatly added to its freight power by the acquisition of new Mallet and Mikado engines; it has also improved transportation facilities generally, especially by the completion of the most modern uptodate electric coal docks at tidewater. These improvements will permit of an increased "miles per car per day" that would, under pressure, equal another 15 per cent. increase in car equipment.

Norfolk & Western Ry. Co.

(By D. E. Spangler, Superintendent Transportation.)

In a statistical way there is little that could be added to the statement we furnished you, 1913, other than to bring those figures up to date, which I do as follows: Number freight engines, 970; tractive power, 40,200,000 lb.; number of coal cars, 34,253; total carrying capacity, 1,733,958 tons. We have also added 46 miles of second track and 79 miles of passing tracks.

While future needs of the trade are entirely problematical, this company is confident of its ability to promptly meet the demands of all mines on its lines during the coming winter. Our facilities, both as to equipment and track, have been increased and improved. Other improvements, such as second track, are still in progress and we should be in position to handle expeditiously, as far as our own rails are concerned, all traffic that may be offered in the near future. However, as much of the coal mined on the Norfolk & Western Ry. is disposed of to markets far beyond this line, we are dependent to a considerable extent upon the prompt release of equipment at destination and the prompt and proper handling of both the loaded and empty cars by our connecting lines.

The Western Maryland Ry.

(By S. Ennes, General Superintendent.)

In March and April of the current year, the Western Maryland received and added to their motive power equipment 20 of the largest type of consolidation freight engines. These are giving us the very best of service, handling during the good weather of July and August 6500 train-tons against a 0.3 per cent. grade line from Cumberland to Hagerstown.

When the new management took hold in March of this year, they immediately sent 40 locomotives to the American Locomotive Works for overhauling. At the present time, with our business equal to that of last year, we have 25 heavy freight locomotives white-leaded, and available for service at any time.

We also took advantage of the dull season to put our cars in first-class shape, and are prepared to handle an increase of 25 per cent. in our coal business with ease. The bridges between Hagerstown and Lurgan and Cumberland and Thomas have been strengthened, so that heavier power can be run in that territory. The track is being put in good shape and as stated, with business approximately the same as last year, we are handling it with ease.

New York Central & Hudson River R.R.

(By Vice-President A. T. Hardin.)

This company has maintained its quota of last year's equipment, which was more than abundant, since all orders were promptly filled. We also have 150 excellent freight engines in reserve for emergencies, and not now being used. We are not, therefore, anticipating any difficulty in the coal-car supply on our lines.

Baltimore & Ohio R.R.

(By J. Hampton Baumgartner.)

Although there was a substantial increase of 475,000 tons in our coal traffic during the last year, this was handled with greater dispatch than ever before and without any material extension of terminal or traffic facilities; this is due to the fact that the road for the first time derived the full benefit of the enlarged facilities provided during recent years at a cost in excess of $100,000,000. The recent inactivity in the building of new facilities was due to financial circumstances, which made it inadvisable to extend facilities beyond the point of urgent necessity.

During the past year this road has added 50 locomotives of the freight type, 3000 new coal cars and 3000 rebuilt cars to its equipment quota, so that at the present time the road has ample coal-car equipment to take care of its traffic requirements.

Included in the plan of extending facilities to increase the number of tracks, was a double-track stretch of line between Orleans Road and Little Cacapon, W. Va., a distance of 11 miles, known as the Magnolia cutoff, which will facilitate the movement on the east end of the Cumberland division. The improvement, which will cost about $6,000,000 and is well under way, will carry toward completion the plan to build a four-track line from Cumberland

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Oct. 1, as follows:

	Surplus	Shortage	Net*
New England Lines	1,007	216	**791**
N. Y.; New Jersey, Del.; Maryland; Eastern Penn.	4,102	0	**4,102**
Ohio; Indiana; Michigan; Western Pennsylvania	17,009	0	**17,009**
West Virginia, Virginia, North & South Carolina	4,534	185	**4,349**
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	3,763	0	**3,763**
Iowa, Illinois, Wis., Minn.; North & South Dakota	3,257	30	**3,227**
Montana, Wyoming, Nebraska	564	0	**564**
Kansas, Colorado, Missouri, Arkansas, Oklahoma	1,544	260	**1,284**
Texas, Louisiana, New Mexico	212	5	**207**
Oregon, Idaho, California, Arizona	2,004	76	**1,928**
Canadian Lines	0	0	**0**
Total	37,996	772	**37,224**

	June 1	June 15	July 1	July 15	Aug. 1	Aug. 15	Sept. 1	Sept. 15
Surplus	94,770	93,520	91,280	93,509	82,284	56,560	46,141	39,558
Shortage	7	49	430	292	110	496	66	191
Net*	**99,351**	**94,763**	**90,850**	**93,217**	**82,174**	**56,064**	**46,075**	**39,367**

***Bold face** type indicates a surplus.

to Brunswick, Md., a distance of 105 miles, and then with the completion of four tracks to Washington Junction there will be a four-track line throughout to the seaboard at Baltimore.

The Magnolia cutoff is in every sense an economic improvement. Besides shortening the distance between these two points via the present line by 5.8 miles, it will effect an elimination of 887 deg. of curvature and do away with a helper grade at Hansrote, which has required the use of an extra engine on eastbound freight trains—the direction in which coal moves—in climbing the mountains.

It is generally recognized by railroad managers of the present day that their properties are never regarded as finished plants, the necessity of adding to them to take care of changes in traffic and business conditions being ever apparent. With this particular road, however, the problem before the management today is one of intensive operation, as there is little undeveloped territory in which lines may be extended.

Illinois Central R.R.

According to the sixty-fourth annual report of this company, issued under date of June 30, the freight-car equipment was increased by 7195 cars and 4065 cars were sold, destroyed or transferred to other service. The net increase was 3130 cars. The average capacity of cars owned at the close of the year was 41.52 tons, compared with 40.24 tons last year. The total capacity of cars was 2,467,995 tons, compared with 2,266,490 tons for 1913.

At the end of the fiscal year 1914 the company had 26,285 coal cars, compared with 23,330 cars for the year previous. This shows an increase of 2955 in the coal-car equipment.

The record of the revenue coal freight for 1914, as compared with 1913, is as follows:

	1914		1913	
	Tons	P.C.	Tons	P.C.
Anthracite	68,450	0.21	90,659	0.30
Bituminous	12,145,945	37.55	10,488,614	34.45
Coke	126,028	0.39	127,680	0.42
Total	12,340,423	38.15	10,706,953	35.17

This shows a net increase of 1,633,470 tons, or 2.98 per cent.

Extracts from a Superintendent's Diary

I have long been of the opinion that the biggest problem now ahead of the men responsible for the future of the coal industry is to succeed in devising ways and means of attracting the boys born and reared in mining camps to coal mining as a life work.

In the old days when miners' sons were given little or no schooling, and were taken into the mines by their fathers as soon as they were able to be of any assistance, most of them graduated into mining from force of habit and only on rare occasions did they have any desire to make a change. But all of that is changed now. In most states, boys are not allowed to work underground until they have passed the age of 14 and in some states the limit is 16. In place of the old indifference to schools, compulsory education is now sweeping the land, and even in the most isolated camps, school bells are not only heard but are respected. Habit will have little weight in the future in shaping a boy's life work, but the decision will be largely dependent on sentiment and imagination.

It is true that when it comes to sentiment, home ties and boyhood friendships are strong invisible links holding the would-be wanderer in line, but it takes something stronger than sentiment to hold a boy back if his imagination is once fired by an outside vision.

And what's to prevent any boy from having his imagination fired by visions these days? Just let him follow the dailies awhile and he'll get all the inspiration he's looking for; furthermore, if he is a normal chap, you may be sure he'll believe he can do anything that anyone else has ever succeeded in doing, and he won't hesitate to try.

When he gets his thoughts back to earth and recalls a vision of tumbled down, unsightly, unsanitary dwellings (one of which is his own home) it doesn't take him long to make up his mind. And then, to complete the impression, if he walks down the street and overhears a conversation between a fireboss and an assistant mine foreman as to the impossibility of either one of them keeping the wolf from the door on the salary they are earning, despite the fact that they had to put in two hard years of night study to get where they are—well he's ready to leave and leave quick.

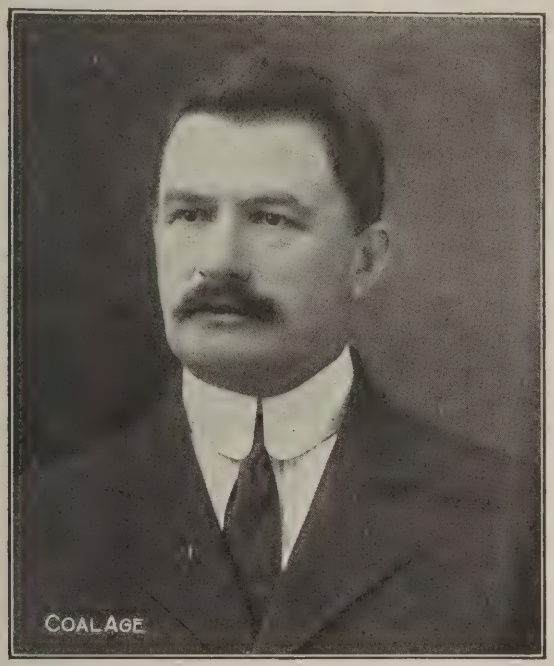
The way the wind might blow was first brought home to me when I began to take an interest in "First-aid work." After our squad had succeeded in getting a little training, a small local gas explosion gave them an opportunity to don the helmets. The next day the youngsters of the camp were all excitement; at last they had something worth while to talk about and, for the time being, they lost all interest in base ball and flying machines and talked about some sure-enough heroes who were living right there in their home town.

And if those same boys in future years, in looking backward, should always recall a pleasant home and neighbor boys, whose fathers were bosses, proud of their work and of their profession, the chances are they will be found earning their livelihood in places where helmets are still in demand on certain occasions.

Sometimes I become much vexed with my big boss when he tries to shut down too closely on my sociological tendencies, as he calls them. In fact, I feel that way toward him just now and I'm putting this justification down in black and white just to get in practice.

Permissible Explosives in Coal Mines

The figures show that in 1902 only 11,300 lb. of permissible explosives were used in coal mining, whereas in 1913 the quantity so used was 21,804,285 lb. The quantity of permissible explosives used in the United States is larger than in a number of foreign countries. In 1912 it represented about five per cent. of the total quantity of explosives produced, and in 1913 six per cent. The total amount of explosives used for the production of coal in 1913 was 209,352,938 lb., of which about ten per cent. was of the permissible class as compared with eight per cent. in 1912. The use of permissible explosives in coal mining has had gratifying results, and few, if any, serious accidents can be attributed directly to their use.



Who's Who in Coal Mining

John Francis Healy

Starting at 10 years of age, doing odd jobs on a mine-surveying corps, and working up to the position of vice-president of a large coal consolidation is the record of J. F. Healy, who is now engaged in mining in Utah.

Mr. Healy was born in Blossburg, Penn., of Irish parents. His early education was received in the common schools of Tioga County, after which he attended the preparatory school of De La Salle College and then the Toronto School of Practical Science in Toronto, Can. His final college training was received at the Pennsylvania State College, where he graduated in 1884.

As stated above, Mr. Healy first became engaged in mining work when only a lad of 10, and continued in this

JOHN F. HEALY

line of employment, off and on, until he was 18. His first serious work after concluding his college course was as engineer in the employ of the Aberdeen, Pierre and Fergus Falls Railway—now a division of the Great Northern. His next place was division engineer with the Nashville & Knoxville Ry.—now the Tennessee Central, after which he entered the employ of the C., N., O. & T. P. Ry. as assistant engineer of maintenance.

This ended his railroad experience, for he accepted a position as mining engineer with the Seattle Coal & Iron Co., Seattle, Wash. He was next identified with the Rocky Fork Coal Co., in Montana, and followed this work by accepting a position as mining engineer with the Davis Coal & Coke Co., in West Virginia. A little later, when the Davis company needed a man to fill the job of general superintendent, Mr. Healy was offered the place, which he accepted and filled to the satisfaction of all. His success with the Davis company led to his next advancement to the position of general manager of the Davis Colliery Co., one of the largest mining corporations in northern West Virginia.

Leaving the Eastern field, Mr. Healy now turned his attention to the Far West, finally locating in Utah, where he is now serving as vice-president and general manager of the Consolidated Fuel Co., Blackhawk Coal Co., Panther Coal Co., Castle Valley Coal Co., Carbon-Emery Stores Co., and Carbon Purchasing Co.

Mr. Healy is a member of the American Society of Civil Engineers, and has taken an active interest in the advancement of mining and civil engineering practice in America. His literary work has been confined to the preparation of a pamphlet entitled, "The American Language." This pamphlet, as Mr. Healy says, "is merely an effort to help Americanize America."

Relation of Observed to Calculated Pressures in Gas Explosions

Attention has often been drawn to the difference between the theoretical pressure of an explosion of gas mixed with air, as calculated from the heats of combustion of the several gases involved; and the actual pressure observed experimentally in the explosion. In this connection, a paper on "The Lost Pressure in Gaseous Explosions," by W. M. Thornton, is of great interest.

In his paper, Prof. Thornton draws attention to the fact that the theoretical or calculated pressures of gas explosions are, in all cases, about twice the pressures observed in the experimental explosion of the gas. From the results of a large number of experiments, he has ascertained the interesting fact that the mean of the ratios of the observed to the theoretical or calculated pressures of gases exploded in air is about one-half.

As is quite well known, the cause of the difference between the theoretical and the observed pressures in gaseous explosions, has been variously attributed to the lack of knowledge of the actual reactions that take place in the dissociation of the elements of the gases and of the products formed. It has, also, been assumed with reason that the specific heats of gases are much higher at the temperature of the explosion than the values determined by experiment. It has been further suggested that there is much loss of heat by radiation and conduction, which has not been accounted and cannot be estimated with any degree of accuracy. A less obvious reason has been suggested to the effect that the maximum pressure of the explosion may be developed before the combustion is complete.

Without casting any reflection on these suggested influences, any or all of which may operate to a degree to reduce the experimental value, Prof. Thornton makes the important suggestion, as drawn from his experiments, that the force of cohesion developed in the formation of the molecule may explain the absorption of a portion of the heat energy of the reaction. He ascribes the pressure and temperature developed in an explosion to what he terms, "translational energy," or the energy imparted from one molecule to another; and reaches the conclusion that the ratio of translational energy of two colliding bodies before and after collision is one-half the total energy developed. The theory, though necessarily incomplete, is suggestive and may prove helpful in the solution of the many problems relating to the explosions of gaseous mixtures.

Editorials

Safety Hints

Several of the railroads are adopting a system whereby they expect to increase the safety of passengers and employees. They supply post cards at each terminal or yard office which their men can obtain and use for the purpose of calling attention to the operating departments of any dangers they may observe in their daily work.

Each of the roads has a standing committee, of which the head officer is chairman. At each divisional headquarters there is a committee, composed of members from each department. The superintendent of the division is the local chairman and he selects the others, who are appointed for a year.

The committees meet monthly and every department is represented. Thus motive power, transportation, signaling and maintenance of way are all duly considered by employees from those several departments.

The post cards filled by the employees are all read by the assembled committee and their value duly considered. They are then printed with comment, each employee being duly credited with the suggestions made. Should, however, the recommendations of the employee be such as to need urgent action, the superintendent accepts the suggestion without delay and wires appropriate orders. For this information we are indebted to E. E. Winters, the chief railroad inspector for the West Virginia Public Service Commission.

We believe that a similar system to that just described could be put in operation at mines. Perhaps a few malicious criticisms might redden the cheeks and ruffle the temper of the superintendent, but, on the whole, it is to be expected that the suggestions would be just and valuable. Some companies, like the H. C. Frick Coke Co., have formed paid safety committees to make reports on mining conditions and are convinced that the experiment makes for safety. The post-card system gives a less limited range for suggestion and might be well worthy of trial.

Much depends on the character of the personnel at the mine as to the success of the movement. In some cases such a system of suggesting dangers to employees would be as fatal as the inquiries of a doctor are to a hypochondriac, who is no sooner asked as to his symptoms than he overwhelms his hearer with a combination of woes no single man ever yet endured.

We recall a coal-company president who took his private car down to the mines and considerately invited the Italian consul to go with him, treating him with consideration of the most distinguished sort. He impressed on the consul throughout the journey, his humanitarian interest in his Italian employees and requested the consul to ask his compatriots at the mine what could be done to increase their safety and comfort.

The consul did so, and the swarthy sons of Italy believed that the strong, omnipresent hand of *"il gran re Umberto"* was behind the consul and their demands for increased wages thereupon resulting blossomed into a strike of no small dimensions. The president lost his interest in the consul and in purposes humanitarian and never again was known to ask for suggestions from that source.

The general attitude of the employees must decide whether the post-card or the committee system will either or both be feasible. It is a piece of socialism and can only be a success when the men have the social sense strongly developed and realize that in this world of ours no finality of safety or comfort can ever be reached and that the burden of safety falls equally on the shoulders of employers and employees.

Profits or Thrift?

Speaking before the Coal Mining Institute of America at the winter meeting nearly a year ago, Harrington Emerson, the efficiency expert, declared that the steamship Mauretania cost roughly nine million dollars, and employed a thousand men. Thus an outlay of nine thousand dollars was needed to supply the wherewithal by which each man on that ship could earn his living. Of course, some operatives are not backed by such an outlay of capital to furnish them with opportunity of efficient labor. Their work would be more serviceable to mankind if they were.

But a careful consideration will lead us to the conclusion that the instance quoted by Mr. Emerson is uncommon in degree rather than in kind, for many mining plants expend more than two thousand dollars for every man they expect to employ. It is clear therefore that large amounts of capital must always be provided, and without pretending to scientific accuracy or a really adequate consideration, we might be excused in saying that the average capital back of a workingman's labor is roughly equal to his year's gross earnings.

There is no reason why the funds needed to supply the workman with tools should be owned by rich men. If the wage of the laborer is not all spent, but if some of it is preserved by thrift, he can invest it and become himself the capitalist. If, however, the workingman, like the average American, raises his scale of living as fast as his wages, the only hope for the citizens of this country is in large profits for the manufacturer and operator. If the workingman will not save, his employer must do it for him or the material for economic production will not be accumulated.

It is in fact necessary that there should be for the future of the workingman, either large profits or universal thrift. Of course, such penuriousness on the part of the workman as decreases his efficiency, by lowering his physical, mental, and even moral status is not thrift. But such economy as makes him a purchaser of only healthful, advantageous and permanent possessions will enable him to enter into the field of the capitalist with benefit to the world at large.

The amount of capital being increased, profits would be lowered and the workingman would get a larger share

of his product in wages. It is sometimes said that profits are necessary to urge capital to invest, and to encourage thrift, but it is even more true that profits or thrift are needed because without them capital could not even exist and labor would be deprived of its tools.

From what has been said, it is clear that the efficient operation of mines demands profits. A starved executive is as inefficient as a hungry laborer. The one has not the equipment for economic operation; the other has not the diet to vitalize his labor.

Let us hope, however, that the time may come here, as it has, perhaps, only come in one country, France, up to the present, where thrift may make profits less necessary to the good fortune of the commonwealth. If every man were to own his own home the result would be a liberation of capital for industry, a boom the like of which this country has never before seen. As it is now, with so much of the wages of the workingman being wastefully spent on ephemeral benefits or even in permanent self-injury, the growth of capital is slow and is most largely provided by what is termed the "greed of capital for profits." The thrift of the masses would be a far preferable basis on which to rear our economic future.

One of the great sources of Germany's rapid rise, as also of the rapid progress of the iron and steel industries in this country, has been the large profits made by reason of the tariffs in both countries and as a result of restrictive syndicates in the case of the German Empire. We cannot feel satisfied that individuals should be enriched at the expense of their employees, but at the same time that the results of large profits are not wholly undesirable is seen in the excellence of the welfare work and of the scientific experimental investigation which in Germany, America and England, have followed wherever profits have been large.

As the world progresses, it is to be hoped that the thrift of the worker will oust the profits of the employer as a source of that accumulated capital which means so much for humanity.

The Daily Press and the Colorado Situation

The presumptuous intrusion of the daily papers into the intricate technical problems of the coal industry has long been a source of distress to the mining fraternity. The editorial and space writers of the big metropolitan dailies criticize coal men whenever and wherever the opportunity is affored them.

In this day of the highly developed super-specialist, the conclusions of such versatile pen artists must be viewed with suspicion. These writers, whose knowledge of the many different issues upon which they pass is of the most superficial character, do not hesitate to pass judgment upon men who have made each of these problems a life study; men who frequently are trained scientists, and whose fathers before them often have lived and died in the service in which they are engaged.

An insidious editorial of this character appeared in the *New York Sunday Times* of Oct. 18, under the caption "Which Union for Colorado." It is written as a reply to a well meaning attempt on the part of President Welborn of the Colorado Fuel & Iron Co., to point out certain inaccuracies in a corrective plan suggested in a previous editorial on this subject in the same sheet.

A seeming justification of their original policy is worked out by a clever evasion of the point at issue, and placing unspoken words in Mr. Welborn's mouth, while an obvious lack of first-hand knowledge pertaining to actual labor conditions in the mining regions of the West, is manifest throughout.

The leading argument is based upon the unfair "inference" that the Colorado operators are opposed to organized labor in any form. It has been repeatedly pointed out that this is not the situation at all in Colorado, and it is surprising to find such a well informed paper as the *Times* playing upon the credulity of its readers in such a manner.

It further contends that the Colorado operators must accept some form of unionism, in proof of which it has much to say regarding the garment and waist makers' strike in New York. It points to the fact that when these workers were finally organized, "the I. W. W. was powerless to make inroads upon the shops," and the further statement, "President Welborn and the other operators of Colorado might do well to consider the complete unionizing of their mines on this basis, if only as a measure of denfense against invasion by organizers whose principles and methods they do not approve."

If this is the case, we would like to have the *Times* explain the complete disintegration of the Butte (Mont.) Miners' Union through the confessed machinations of the I. W. W. element. The Butte Union was the most powerful organization of its kind in the world, so much stronger than any of the Eastern sweatship unions that there was no comparison between the two; and yet almost overnight, the I. W. W. precipitated such a riot that the National guard was compelled to almost take the town by assault, planting their machine-guns in the main thoroughfares, while the National Government at Washington rushed a reserve detachment of regulars to Helena, a few miles away.

While we are not in any way opponents of organized labor, it being generally conceded by all enlightened thinkers of today that legitimate unionism possesses certain advantages for all concerned, it is yet to be proved that mining operations cannot be satisfactorily conducted in any other manner. The fallacy of such a conclusion has been conclusively disproved by a number of large concerns, notably the Berwind-White Co. The Berwind interests have developed into one of the very largest coal producers in the United States, and it is a well known fact that they will not permit unionism or organization in any form at their operations, and yet there are but few mining companies in this country where the owners have experienced less labor trouble or where the working men enjoy such unexcelled advantages of all kinds.

There is no disputing the fact that for use in the smaller types of battleships liquid fuel possesses an immense advantage: (1) In simplifying ship design; (2) in affording ability to obtain and maintain great speeds; (3) in providing a far wider range of action, and (4) in diminishing the numbers and strain upon the personnel. Another great advantage is the ease with which oil-burning ships may be refilled at sea. Oil can be fed easily from one vessel to another without returning to port, and this adds an appreciable percentage to the relative fighting strength of the navy.

Sociological Department

The Utah Annual First-Aid Meet

By OTTO HERRES, JR.*

The Utah annual first-aid contest was held at Price, Carbon County, Utah, on Saturday, Sept. 26, under the auspices of the Carbon-Emery Fair Association, with the active cooperation of the important coal-mining companies of the state. This was not only the first state-wide contest ever conducted in Utah; but it was also the first intercompany meet to be held in the state.

Thirteen teams were entered, each representing the best of their respective mines. The contesting teams represented the Consolidated Fuel Co., the Castle Valley Coal Co., the Black Hawk Coal Co., the Independent Coal & Coke Co., the Spring Canyon Coal Co., the Standard Coal Co., and the Utah Fuel Co.

Excursion trains were run from the closer districts, and notwithstanding the difficulties of mountain travel, each team had a large following. About 1500 visitors from the mining camps were in attendance during the entire time of the contests, remaining on the field or in the grandstand until the final tie had been decided. A large percentage of the leading coal-mining officials of Utah were present, and each one of them followed the various events with more than ordinary interest, on account of the general excellence of the work and closeness of results.

The field for the contests was laid out on the Price baseball diamond and race track, in a rather unique manner. Two rows of 12-ft. squares were outlined with white paint in the shape of a "V." The wide end of the "V" opened and was close to the grandstand so as to permit the spectators to view the work of every team. The ground was roped off, and the numbers of the various teams were suspended from the ropes in the rear of the square where each team worked. No one was permitted within the ropes except contestants and presiding officials. All announcements to the contestants and spectators were made through megaphones. Positions on the field were drawn by lot by the captains of the various teams.

The judgment of events was in charge of representatives of the United States Bureau of Mines, assisted by State Coal Mine Inspector J. E. Pettit and Dr. F. R. Slopanskey. No surgeon or official connected with the companies competing was

*Mining engineer, Castle Gate, Utah.

CASTLE GATE MINE NO. 2, THE WINNING TEAM

SPRING CANYON COAL CO. TEAM WINS SECOND PRIZE

TEAM FROM STANDARD MINE WHICH TIED FOR FIRST PLACE IN THE TWO-MAN EVENT, AND SECURED SECOND PLACE IN THE THREE-MAN EVENT

TEAMS AND JUDGES WORKING ON FULL-TEAM EVENT—COMPOUND FRACTURE, LEFT HIP; DISLOCATED RIGHT HIP; SIMPLE FRACTURE, RIGHT FOREARM

TEAMS IN THE TWO-MAN EVENT. FACE, FOREHEAD AND EARS BADLY BURNED, BROKEN LEFT KNEECAP

allowed any part in the judging. The number of judges was such as to allot one to each two teams, and the judges were placed with different teams on successive events to eliminate the personal equation as much as possible. The judges were: J. C. Roberts, U. S. Bureau of Mines, chief judge; Dr. A. J. Lanza, U. S. Department of Health; J. E. Pettit, State coal-mine inspector; Dr. F. R. Slopanskey, Denver & Rio Grande R.R. surgeon at Helper, and J. L. Boardman, J. T. More and K. H. Chisholm, of the U. S. Bureau of Mines, First-Aid Department.

Other officers were: Marshall, Sheriff T. F. Kelter, Price; recorder, J. C. Snow, Castle Gate; timer, H. E. Lewis, Hiawatha; announcer, J. H. Hammond, Price.

Committee on arrangements consisted of Dr. E. M. Neher, Castle Gate; Dr. J. E. Dowd, Hiawatha, and Dr. Hal. Robinson, Storrs.

The contest was divided into one-man, two-man, three-man and full-team events. These were held in the morning from ten o'clock until noon. After a recess for dinner the scores on the morning's work were tabulated and the ties worked off during the afternoon.

Prizes were in cash and aggregated $450. The first prize of $150 was won by Castle Gate Mine No. 2 team, with a perfect score in all events. The Spring Canyon Coal Co. team won the second prize of $75.

There were ties in the one-, two- and three-man events, and it was with difficulty that these contests were decided, as the contestants were well trained and made few errors. Bandages were applied and placed with exceptional skill and neatness. After a third problem had been given to decide the tie in the two-man event, all seven judges acting together were unable to deduct from the perfect scores of the Standard team and Sunnyside Mine No. 2 team.

The prize winners were as follows:

Grand Prize—First prize, Castle Gate Mine No. 2, $150; second prize, Spring Canyon Coal Co. Mine, $75.

One-Man Event—First prize, Sunnyside Mine No. 1, $25; second prize, Sunnyside Mine No. 2, $12.50.

Two-Man Event—First prize, tie between Standard Mine and Sunnyside Mine No. 2, $50; second prize, Hiawatha No. 1, $25.

Three-Man Event—First prize, tie between Mohrland No. 1 and Mohrland No. 2, $75; second prize, tie between Kenilworth, Sunnyside No. 1 and Standard Mine, $37.50.

The following problems were given:

One-Man Event—Patient found with cut on right temple; severe bleeding. Treat and carry 50 ft.

Two-Man Event—Face, forehead and ears badly burned, broken left kneecap. Treat and carry 50 ft.

Three-Man Event—Patient is found unconscious with face downward and lying on live wire (carrying 4000 volts), with chest severely burned. Treat and carry 50 ft.; use improvised stretcher.

Full-Team Event—Compound fracture of left thigh; severe arterial bleeding; dislocated right hip; simple fracture of the right forearm. Treat and carry 50 ft.

Problems in working off the ties were:

One-Man Event—Treat patient for crushed right foot and compound fracture of nose.

Two-Man Event—Treat a man found in blackdamp under a fall of rock, unconscious, with compound fracture of left thigh and bone projecting inward.

Three-Man Event—Treat a patient for severe burns of the hands; a deep cut of the abdomen just above the umbilicus with bowels protruding.

The rules, under which the meet was held, are identical with those in force at the Utah Fuel Co.'s meet described on p. 348 of the issue of Aug. 29, 1914, with a few changes. Thus the demerits in Rule 17 of the Utah Fuel Co. meet had in this contest this important addition: For improper treatment, five points, and Rule 11 was changed providing that teams with the same score shall be required "to participate in another similar event" instead of in a contest between the full teams so tieing.

E. K. HOLLAND, SECOND-PRIZE WINNER IN ONE-MAN EVENT, WITH J. W. LITTLEJOHN, PATIENT

Rule 12 being about the challenge cup was naturally omitted, and Rule 16 about the hour of contest was also changed. Two rules of interest are added, namely: Rule 18: Members of teams participating in the one-man event, two-man event and three-man event, will be barred from all other events except that for full teams. Rule 19: Every team entering this contest must procure a certificate from its respective mine superintendent to the effect that the members are regular employees of the company, and that their entrance into the contest is approved by their superintendent.

Each event was marked on the basis of 100 points for a perfect score; then divided by 5 to give 20 points for each member of the team working; and multiplied by the number of men in the event. Thus, a perfect score for the one-man event was 20; two-man event, 40; three-man event, 60; full-team event, 100, and total score, 220 points.

The personnel and scores of the best teams follow:

Castle Gate Mine No. 2: Robert J. Henderson, captain; Jack Ramage; Jack Hreinson; Albert Wardell; James Lakin and Leonard Taylor. Score 220.

Spring Canyon Coal Co.: S. H. Short, captain; Ben Sellars; Fred Thomas; Bert Davis; John Harrison and John Haddow. Score, 216.2.

Sunnyside No. 1: Ernest Lloyd, captain; Henry Stobbs; J. W. Dunn; James Thorpe; Jack Turner; Eugene Singleton. Score, 215.2.

Sunnyside No. 2: J. W. Littlejohn, captain: M. H. Detwiler; J. T. Johnson; J. Patterson; E. K. Holland and Zeph Thomas. Score, 214.4.

The other teams made the following scores: Standardville, 213.2; Mohrland No. 2, 212; Hiawatha No. 1, 211.4; Mohrland No. 1, 210.6; Utah, 209.6; Black Hawk, 209.2; Winter Quarters, 209; Kenilworth, 202.8; Hiawatha No. 2, 190.4.

The character of work performed by the various contestants was highly commended by the judges and surgeons present at the meet. Individual efforts compared very favorably with those shown at any of the large meets of the East. Great proficiency in bandaging was displayed by several teams.

Although the safety-first movement is not new in the state and some of the mines have trained men in first-aid work for many years, the past year has shown both the miners and the various mining companies working together with greater interest than ever before, and the results seem commensurate with the greater efforts expended.

First-Aid Meet of the "Old Company"

The Lehigh Coal & Navigation Co., familiarly known as the "Old Company" in the Anthracite region, because it is the oldest in the history of mining in this country, held its annual outing at Lakeside Park, East Mahanoy Junction, Aug. 29 of this year.

As usual the meet while giving first place to first-aid, also comprised field and water sports. The problems were as follows:

1. Treat a foreign body in the left eye, and laceration of left hip. One-man event. Time, 3 min.
2. Treat a simple fracture of left collar-bone, and laceration of scalp. Two-man event. Time, 3 min.
3. Treat a simple fracture of left thigh, and a compound fracture of right upper arm. Team event. Time, 10 min.
4. Treat a fracture of left kneecap, a fracture of right thumb, and extensive lacerations over right shin bone. Team event. Time, 10 min.
5. Treat conditions of a man who has fallen on an electric wire, back down, whose clothing is burning; rescue, extinguish fire, treat patient and dress back and upper arms. Team event. Time, 10 min.

The judges were as follows: Drs. E. H. Kistler, W. H. Kastem, M. H. Neumiller, W. F. Ely, W. C. Scott and R. Kistler, of Lansford; Dr. J. E. Beale, of Coaldale; Dr. W. H. Hinkle, of Tamaqua; Dr. J. H. Behler, of Nesquehoning, and Dr. B. A. Erwin, of Mauch Chunk .

The first prize of $25 in gold and individual silver medals

The Crowd at the Annual Outing of the Lehigh

was won by the Nesquehoning Outside Team, consisting of William J. Adams, captain; Oscar Strohl, Clarence McGerry, William Strohl and Samuel Azer. The second prize of $15 in gold fell to the Electrical Department—Harold Ramsay, captain; Thomas Wildin, George Israel, Harry Wheinmeyer and Warren Holmes. The third prize of $10 was secured by Daniel J. Jones, captain; George Boyle, David Morgans, James Cunningham and Edward Minnick.

The ratings of the teams in the contest follow:

Team	Captain	Per Cent.
1—Nesquehoning Outside ..	W. J. Adams	100
2—Electrical Department ..	H. Ramsay	100
3—Lansford Shops	D. James	99⅛
4—Tamaqua Inside No. 2..	C. Erbe	98
5—Coaldale No. 9 Shaft.....	D. Moser	97
6—Lansford Outside	A. Gibson	97
7—Coaldale No. 8 Slope.....	T. J. Evans	96⅝
8— Nesquehoning Tunnel 2	P. Bouse	96⅛
8— Coaldale No. 8 Shaft ..	J. Boyle	96⅛
8— Greenwood Inside	W. Sweeney	96⅛
11—Nesquehoning Shaft No. 1	T. Hoffler	96
12—Tamaqua Inside No. 1 ...	O. Belts	95⅛
13—Nesquehoning Shaft No. 2	J. Lewis	94⅛
14— Nesquehoning Summit..	J. Forest	94⅛
14— Lansford No. 4 Slope...	A. McMuller	94⅛
14— Lansford No. 3 Shaft...	S. Hollenbach	94⅛
14— Hauto Washery.....	E. Mulhearn	94⅛
15—Nesquehoning Tunnel No. 1	C. Keeney	93⅞
19—Tamaqua Outside	C. Gould	93⅛
20— Lansford No. 4 Shaft..	H. McElmoyle	92⅜
20— Lansford No. 6 Shaft...	D. Cunning	92⅜
20— Coaldale Outside	W. Callahan	92⅜
23—Rahn Shaft	J. Filer	92⅛
24—Springdale	T. Whildin	90
25—Greenwood Outside	R. Werner	89⅜
26—Foster's Tunnel	T. Thomas	88⅛

The contest for supremacy in field sports followed. Each district had a limited number of representatives in each event.

The water sports were: 50-yd. swim with turn, 300-yd. single-oar boat race, chasing the duck, 100-yd. straightaway swim and 400-yd. double-oar boat race. The contestants representing different districts competed with each other, and a summary of points made by the contestants from each district provided a way of comparing the skill of the men thus classified. Lansford won with 16 points, Tamaqua being second with 14. Coaldale and Nesquehoning tied with 6 points, while Greenwood scored only 2 points.

The field sports were: Standing broad jump, 50-yd. dash for men over 50 years of age, 50-yd. dash for men weighing over 200 lb., running broad jump, 600-yd. two-legged race, 100-yd. dash, putting 16-lb. shot and tug-of-war. Lansford again won, with 26 points; Greenwood made 25, Tamaqua 12, Coaldale 7 and Nesquehoning 1 point. As a whole, Lansford won easily with 42 points, Greenwood having 27 and Tamaqua 26, but Coaldale made only 13 and Nesquehoning 1 point only.

A baseball game was played between teams from Carbon and Schuylkill Counties, the winning team receiving $25. A dinner was served in the grove.

Coal and Navigation Co. in Lakeside Park, Aug. 29, 1914

Legal Department

Duty of Operator Concerning Safety of Mine

By A. L. H. Street*

In reversing a judgment which was awarded against defendant for death of a miner, caused by fall of a mine roof, the Washington Supreme Court decided these points in the recent case of Lindquist vs. Pacific Coast Co., 142 Pacific Reporter: The legal principle that where an employee's place of work is constantly changing, as in the case of mining, he is presumed to assume risks of injury arising from the performance of his work, did not apply in this case, it appearing that the accident occurred in a room which was being operated on the pillar system. The foreman had inspected the place in the roof where a squeeze appeared, pronounced it to be safe, and directed the deceased employee to work there. The latter remained at work under such direction until the middle of the day, when the roof fell.

A workman who follows the assurance and judgment of his employer's representative, will not be charged with assumption of risk or contributory negligence, as a matter of law. The assurance is not that one blow may be struck or one shovelful of earth turned in safety, but that the place is safe long enough to accomplish the thing to be done, which, in this case, was to remove the coal from that part of the pillar where the squeeze occurred. But, if defendant company furnished a sufficient supply of timbers at the entrance of the working place, it could not be held responsible for the accident, merely because it did not provide for cribbing instead of posts and caps, and did not keep the chutes open on both sides of the section which was being worked, so that the coal might be removed from either side.

The requirement under the Washington laws that coal-mine operators shall deliver timbers for supports "at the entrance to the working place," is not shown to have been violated by reason of the fact that the timbers in this case were placed about 250 ft. from the place where they were to be used. It was a question for the jury to determine whether it was proper mining in this case to remove the coal from one side of the section to another, and whether the fact that the chutes on one side had caved in would charge the miner with assumption of the risk or contributory negligence.

Recent Judicial Decisions

Validity of Virginia Wage Law—The Virginia statute which prohibits coal operators and manufacturers from issuing orders in payment of wages, unless such orders are redeemable in cash, is valid. (United States Supreme Court, Keokee Consolidated Coke Co. vs. Taylor, 34 Supreme Court Reporter 856.)

Proof of Negligence in Fatal Injury Cases.—Mother's Right to Recover Damages.—A coal company cannot be held responsible for death of an employee in an accident to which there were no eye witnesses, on mere conjecture as to the cause of the accident; there must be proof reasonably tending to show that the injury was caused by some act of negligence attributable to the company. But, in the absence of evidence to the contrary, it will be presumed that the employee was in the exercise of ordinary care for his own safety. Under the laws of Wisconsin, the mother of an illegitimate son is entitled to recover damages for his death due to negligence of a third party. In any case a mother will not be permitted to recover on account of a prospective loss of support by her son after he would have attained his majority, unless there is evidence showing such loss to a reasonable certainty, and the amount thereof. (Wisconsin Supreme Court, Andrzejewski vs. Northwestern Fuel Co., 148 Northwestern Reporter 37.)

Mechanic's Liens Against Mining Property—A lessee under an ordinary lease for mining coal on a royalty basis is not a "contractor" of the landowner in such sense as to entitle his employees to enforce a lien against the property. (Colorado Court of Appeals, Empire Coal Co. vs. Rosa, 142 Pacific Reporter 192.) In denying the right of employees of a lessee to a mechanic's lien, the court said: "The work done, as shown by the evidence, was that usual, ordinary, and necessary in the regular course of operating a coal mine, in extracting coal therefrom, although involving a small amount of 'dead work,' driving an entry (but whether in coal or not is not disclosed), and laying some track. Besides, it nowhere appears what part of the labor sued for was performed in doing anything that might be termed development, preservation, or improvement of the mine, as distinguished from the mere extraction of the coal, and if some items are lienable, the amount cannot be ascertained from the evidence so as to form the basis of a decree."

Employer's Duty Concerning Safety of Mine Roof—When a mining company's foreman undertakes to inspect the roof of a mine room to ascertain whether it is safe for a miner who is about to work under it, the company, acting through the foreman, is bound to exercise a reasonable degree of care to discover any dangerous conditions existing in the roof, even though it may ordinarily be the duty of the miner to look after the safety of his own room, the company merely providing props. Hence, if it appeared in a suit for injury to a miner, caused by rock falling on him, that, being somewhat inexperienced, he asked his foreman whether he thought any more of the roof would fall, and the foreman tested the roof with a pick and assured plaintiff that it was safe, the jury were warranted in finding that the injury was due to negligence attributable to the company, if the foreman's failure to make a proper inspection resulted in his overlooking the dangerous condition which caused the injury, and if plaintiff was induced to continue his work, in reliance upon the foreman's assurance. (Missouri Supreme Court, Manufacturers Coal & Coke Co., 168 Southwestern Reporter 927.)

Width of Barrier Pillars in Pennsylvania Mines—A Pennsylvania law enacted in 1891 requires the owners of adjacent coal properties to leave a boundary pillar sufficient as a barrier for the safety of the miners in each of the adjoining mines, in case the other should be abandoned and filled with water. The width of the pillar is to be determined by the engineers of the adjoining property owners, together with the inspector of the district in which the mines are situated. This law has just been before the Pennsylvania Supreme Court again in the case of Mill Creek Coal Co. vs. Curran, 91 Atlantic Reporter 424, a suit brought to declare illegal an award fixing the width of a barrier pillar of coal between the mines of two operating companies. Summed up, the court's opinion, in effect, is that the law was a valid exercise of the legislature's power; that the power given to determine the width of a barrier between two given mines includes authority to determine whether the safety of employees in the two mines requires a pillar of any width; that a decision by the engineers and inspector fixing the width of a pillar will be presumed to have been reached after considering the necessity for any pillar at all; and that a valid decision may be reached by a majority of the members of the board created by the law.

Discussion By Readers

Gasoline Mine Locomotives

I read with much interest the letter of E. W. Hamilton, COAL AGE, Sept. 12, p. 440, drawing attention to the particular advantages to be derived in the use of gasoline locomotives, in mine haulage.

In this connection, I wish to refer briefly to some very important facts brought out in a recent paper read at the Pittsburgh meeting of the American Institute of Mining Engineers, October, 1914, by O. P. Hood, Chief Mechanical Engineer of the Federal Bureau of Mines. In his paper, Mr. Hood has enumerated some of the results of the extensive experiments made by the bureau to determine, as nearly as possible, to what extent the use of gasoline motors is dangerous to life or injurious to the health of miners, under the worst possible conditions that may exist in the operation of coal mines.

After speaking of the "great flexibility, ease of control and economy of operation" of electric haulage and the "serious menace" of the trolley-wire system of distribution, Mr. Hood gives equal emphasis to the "greater flexibility of application" secured by the use of gasoline locomotives in mines, without a similar dangerous distributing system. He contrasts the danger of death by electric shock with the injury to health and possible death by the corruption of the mine air with the exhaust gases of the engine. He states that these gases consist of "nitrogen, a little free oxygen, hydrocarbons, hydrogen, carbon monoxide and carbon dioxide."

The exhaustive study made of mine air and gases, by the engineers of the bureau, to which Mr. Hood refers, (Technical Paper No. 62, U. S. Bureau of Mines) leads him to conclude that the determining factor, in respect to the danger arising from the use of gasoline motors in mines, is the presence of carbon monoxide in the exhaust gases of the engine. He adds that the percentage of this gas in the mine air will depend upon the amount of the gas present in the exhaust, as compared with the quantity of air passing on the haulage road; but he considers that it will be necessary to provide ventilation for the worst condition that can result.

It is stated that while, under normal running conditions, this gas rarely exceeds 6 per cent. of the total exhaust, the quantity may, owing to a bad adjustment of the carburetor, be increased to 13.5 per cent. It is clear that since such a wide variation in the percentage of this dangerous gas is possible, this fact coupled with the possibility of a slack ventilation on roads or in places where the locomotive may be working, makes it necessary to observe great caution in the use of these machines.

Mr. Hood gives a table showing the percentages of carbon monoxide and carbon dioxide gases that may be produced by the different sizes of engines in common mining use, number of cylinders, speed (r.p.m.) and piston displacement, together with the quantity of air required to dilute the carbon monoxide to 0.1 per cent. He draws attention to the possibility of the locomotive running in the same direction in which the air current is traveling and perhaps with the same speed or velocity, in which case the gas would reach a dangerous percentage in the air to which the engine runner would be exposed. He mentions also the danger of permitting a gasoline locomotive to stand idle for any length of time, except in an ample ventilating current, and advises the use of a self-starter on all gasoline locomotives.

MINING ENGINEER.

Pittsburgh, Penn.

Waste under the Ohio Mine-Run Law

All familiar with the systems and methods of mining coal now employed, in eastern Ohio, know that not more than 65 per cent. of the coal is recovered or mined as marketable coal. As slack is being sold today, in the Cleveland market, for 15c. a ton, one cannot but feel that there is considerable reason in the resistance that is being made, by the coal operators in the No. 8 Ohio field, to the mine-run law that a short-sighted government has forced upon an already superlegislated industry.

Under the operation of this law, the miners are not concerned in the amount of slack and fine coal that they load into the cars. It is passing strange that legislators charged with the duty of enacting such laws as will prove a benefit to the state, its industries and the workers, alike, should continue to whittle down the small margin by which the coal industry lives. That the state of Ohio is losing hundreds of thousands of tons of coal, in the No. 8 field, is a fact known to all miners, operators and inspectors alike. In my opinion, time will undoubtedly fix the responsibility for this waste and loss, not upon the industry but upon the law-making body, for the enactment of laws that serve no other purpose than to waste the resources of the state by compelling a profligate system of mining.

There is, in the recently enacted mine-run law in Ohio, an innocent and harmless looking item, which the miners' union forced upon the operators of the No. 8 field, to the effect that "rooms shall be 24 ft. wide, with the track in the middle of the room." This practically lays down the law in regard to the system of mining to be adopted; and compels the operator to consent to a heavy loss both to himself and to the state. The method of laying the track in the middle of a room, as all mining men know, precludes the drawing of pillars, under most conditions in coal mining; because the drawslate and other refuse is gobbed against the pillars and must be removed before the work of drawing back the pillars can be commenced. The cost of removing this waste would be prohibitive, and the pillar coal would be often abandoned.

In the Pittsburgh district, the same union, inspired with a greater sense of justice, agreed that the track in the rooms should be laid close to one rib, which enables the pillars to be drawn back with little expense. All mining men know how important it is to obtain the largest possible percentage of coal from the rooms, to offset the

expense of driving narrow-work. On this account, it frequently happens that mining in the rooms is allowed to encroach upon the entries; and, under the conditions, one can hardly blame companies for this practice; although if it is carried too far, a squeeze is the almost inevitable result.

Besides the great waste it entails, there is no doubt in my mind that this system is responsible for a large percentage of the fatal accidents occurring daily in that field from falls of roof. If this be true, it is a matter that should concern the chief inspector and the safety commission. In respect to the unwarrantable waste of natural resources, this condition should interest every citizen, whatever his calling or standing.

Were it not for the prescribing of the system of working, by the union, in the manner to which I have referred, operators would be in a position to reduce the present waste in mining to a minimum, by adopting a system better suited to the conditions and which would guarantee the extraction of the largest possible percentage of the coal. While the union conceded this privilege to the operators in the Pittsburgh district, it was withheld from those in the No. 8 field, which was manifestly an unfair discrimination.

We may ask, Why is this system permitted, which entails so large a waste and great financial loss, and is a constant menace to life and causes an increased demand for compensation for injuries, besides other losses to the operators? Is it not evident that such laws are adding to the heavy burdens already borne by coal operators in this field? Is it possible that law-makers do not realize that while such laws may be a benefit to a few, they impose unjust burdens on the large majority? If such be true, they are betraying the trust placed in them.

One is forced to the conclusion, however, that under the working of the spoils system and the desire for long terms of office, the influence of the miners' union is allowed to control the better judgment of men who have it in their power to adjust these matters. It is to be regretted that, under this influence, the coal operator is rapidly becoming known as a common enemy, instead of the mainstay and support of a large and necessary industry. Such a situation is as deplorable as the strikes, that result, are expressive.

The demands on the coal operators of the No. 8 field are greater than those in any other district, as far as my knowledge goes. One great source of trouble is that, under existing conditions, each mine is a law unto itself, there being no general agreement. For example, one mine will be thrown idle if eight men are out of coal; another, if 10; and still another if 12 men so elect. The penalty for loading dirty coal differs in almost every mine. The occurrence of morning meetings in the mines, after all the daymen have entered, causes frequent stoppage of the work and a loss of two or more hours, which is a serious matter in the successful operation of a mine.

As a practical example of the interference of the union, in the operation of the mine, one local even essayed to prevent the superintendent of the mine from picking chunks of slate, sulphur, etc., off the top of the loaded mine cars, claiming that every car must first be weighed and its weight credited to the miner, who should be docked the necessary amount, after the coal is dumped. In this case, after a six days' strike, the men became more reasonable.

In closing, permit me to say that, until the coal operators, in the No. 8 field, are permitted to adopt their own system of mining, and until there is a greater desire on the part of the men in that district to live and let live, there can be neither success, satisfaction nor peace.

Charlton Dixon, Gen. Mgr.,
Franklin Coal Co.

Pittsburgh, Penn.

The Mine Foreman

Letter No. 11—I have often wondered why we do not hear more frequently, by way of discussion and the writing of practical articles, from the mine foremen of this country. There is not a man engaged in the coal industry who comes into closer contact with the practical side of mining than the mine foreman. As a class, they are busy men and often have little to say; but it is not because they have nothing to write about. If these men were so disposed, many of them could produce articles that would be of great interest to their fellows.

There is no occupation in which men are engaged that presents more varied conditions and experiences than the mining of coal. The mine foreman finds some fresh difficulty each day. His mind dwells constantly on the work. At home, he goes over plans for the next day, studying what will be the best and most economical way of making necessary changes or performing the daily routine work of the mine. In all his plans, the questions of safety and expense are of the first importance.

In the mine, the foreman is constantly confronted with questions that often demand an immediate answer, yes or no. In many cases, his decision will mean hundreds of dollars saved or lost to the company. It is important, therefore, that the mine foreman be a man of keen and reliable judgment. He must be able to work his men to the best advantage, and to secure the highest efficiency from their labor.

There is a great difference between considering a plan or method outlined on a map, when sitting at home or in the office, and being required to carry out the same work or execute the same plan in the mine. When a plan is handed to a foreman, he must consider how the work can be done in the quickest manner and with the least expense. He must regard the safety of his men and the requirements of the mining law, in respect to the work.

In a large mine where the mine foreman has a number of assistants who are in charge of different branches of the work, his duties require a general oversight of the mine, to see that the work is well done and the least expense incurred in the operation. Such a general oversight requires the broadest knowledge and judgment, both in respect to the men employed in different kinds of work and the manner in which that work should be accomplished.

In most mines, however, the foreman has little help and must give his entire attention to every detail of the work going on in the mine. He must be informed of every bad or dangerous rock, bad track, or a switch where cars are frequently derailed; and see that the trouble is overcome or the difficulty removed. At the same time he must keep things moving. He must see that all material required is at hand and brought into the mine and delivered promptly where it is to be used.

The mine foreman must inspect every working place while the men are at work, to ascertain that the coal is properly mined and loaded and the face suitably timbered and safe for work. He must see that each man has his needed supply of cars, timber and tracking, and that the place is well ventilated and free from gas. He must inspect the haulage roads, arrange the work of the drivers so that there will be the least delay and the coal arrive regularly and promptly at the bottom of the shaft or slope.

In these days of sharp competition, when machinery of all kinds and for all purposes is being introduced into the mines, it is essential that a mine foreman shall be familiar with the general principles of every class of machine, so that he will be able to judge of its practical adaptation to the work in the mine.

Again, the task of the mine foreman is rendered much more difficult, by reason of the fact that 95 per cent. of the men employed, in many mines, are foreigners and cannot speak the English language. The most of these men can only be made to understand by means of signs. Their instruction in regard to the safest and best method of mining coal requires much time and patience. The presence of these foreigners in the mine is a source of constant worry to the mine foreman, for fear that something will go wrong at any moment. Their ignorance of conditions or neglect of the simplest precautions may cause an accident that will cost hundreds of dollars and, perhaps, jeopardize the life of every man in the mine.

Mine foremen, as a rule, are hard-working, conscientious men. In most cases, they shoulder their own burdens and do not trouble their superintendents with many small matters, although these may be a source of continual annoyance and trouble to them. In some cases, it would be better if the foreman would take up many small matters with his superintendent, with a view to the removing of the difficulty, as it often happens that a small matter neglected will grow to much larger proportions; and the expense of removing the difficulty will be much greater than if proper attention had been given the matter earlier.

It is a great help to the mine foreman when his superintendent is not too busy to go over matters with him in detail. This sociability shows that the superintendent has the welfare of the foreman and the men at heart; and the knowledge is a satisfaction to the foreman, who is encouraged thereby to greater effort. Such encouragement is greatly needed, because of the arduous work with which he is charged.

THOMAS HOGARTH, Mine Foreman,
Penn-Mary Coal Co.
Heilwood, Penn.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

Duty of a Pump—There are different definitions for what is termed the "duty of a pump," each giving a different estimate or value.

The duty is sometimes defined as the weight (lb.) of water raised through a vertical height of 1 ft., for each 100 lb. of coal burned; or, more simply, the theoretical work (ft.-lb.) performed, per hundredweight of coal burned under the boiler.

It is observed that this definition is faulty, because it combines furnace and boiler efficiencies with that of the pump itself, besides estimating only the theoretical work performed, thus eliminating friction, which is often a most important factor.

The true definition of **duty in pumping** is the actual work performed in a given time (ft.-lb.), per million B.t.u. delivered to the pump in the same time. Or, less frequently, the duty is estimated in foot-pounds of work performed, per thousand pounds of dry saturated steam consumed.

Steam Consumption in Pumping—The common type of direct-acting pump, so much employed in mining, is well known to be wasteful in respect to the consumption of steam. This is owing to the necessity of using steam at full pressure throughout the entire length of stroke. Only a comparatively few pumps are designed to use steam expansively and these are not adapted to the commonly high lifts in mining.

Steam consumption, in pumping, ranges from 10 or 15 lb. per i.hp. per hr., in triplex, flywheel pumps when run condensing, to an average of 150 lb. per i.hp. per hr. in direct-acting pumps. The consumption of steam, in pumps of the latter type, varies from 100 to 200 lb. per hp. per hr., depending on the speed of the pump and its condition. In this class of pumps, the consumption of steam is less as the speed is increased.

To Calculate Steam Required to Operate Pump—For a direct-acting pump in fair condition, operated at a piston speed of 100 ft. per min., assume an average steam consumption per indicated horsepower-hour of, say 150 lb. dry saturated steam, which is a so called **"water-rate"** of $150 \div 60 = 2.5$ lb. per i.hp.-min.; and multiply this water rate by the indicated horsepower of the pump, as shown by the following:

Example—Find the steam required to pump 9000 gal. of water per hour, from a shaft 450 ft. deep, using a simple direct, double-acting pump running at a speed of 100 ft. per min., and discharging through a 3-in. column pipe.

Solution—The effective head, in this case, is

$$h_1 = 450 + \left(\frac{9000}{60}\right)^2 \frac{450}{800 \times 3^5} = say\ 502\ ft.$$

The indicated horsepower of this pump will then be

$$H = 0.00034 \times 150 \times 502 = 25.6\ hp.$$

The weight of steam required to operate this pump, under the assumed conditions, will be

Steam consumption, $2.5 \times 25.6 = 64$ *lb. per min.*

The Coal Age Pocket Book

To Calculate the Duty of a Pump—First, find the horsepower required to operate the pump under the given conditions, which is the indicated horsepower of the steam cylinder and may be calculated from the work performed in the water-end of the pump, assuming for that purpose a mechanical efficiency of, say 75 per cent. Multiply this horsepower by 33,000 to reduce to foot-pounds per minute.

Now, find the heat units (B.t.u.) per pound of steam used in the cylinder each minute, and multiply this **heat value** by the **water-rate** for the class of pump employed, and that product by the indicated horsepower, which will give the total heat (B.t.u.) converted into work each minute.

Finally, since this total heat energy is to be expressed in million B.t.u when estimating the duty of a pump, multiply the foot-pounds of work performed each minute by 1,000,000 and divide the product by the total heat consumed in the same period of time. The quotient obtained will be the duty of the pump expressed in foot-pounds.

It is **important to observe** that the basis of estimating duty, in pumping practice, is purely an arbitrary one and varies greatly among engineers; so that it is necessary, in giving the duty of a pump, to state the basis of estimate employed. Otherwise, the duty given is of no value as demonstrating the efficiency of the plant.

Duty is very commonly estimated, as above, on a basis of million B.t.u.; or, as many engineers prefer, on a basis of thousand pounds of dry saturated steam consumed, per unit of time. Aside from this difference, however, the heat in the steam is sometimes taken as the total heat above 32 deg. F. and sometimes above the feed-water temperature. The latter method would seem to be preferable inasmuch as it considers the ratio of the work performed, to the heat in the steam derived from the combustion of the fuel in the furnace. It eliminates the heat imparted to the feed water by the condensation of waste steam in the feed-water heater. It may therefore be a better index to the comparative cost of pumping, without confusing the efficiencies of the pump, boiler and furnace.

Example—Referring to the last example, where it was found 25.6 hp. was required to pump 9000 gal. of water an hour, under an effective head of 502 ft., assume a feed-water temperature of 100 deg. F. and the diameter of the steam-end double that of the water-end and find the duty of the pump, on the B.t.u. basis, above feed-water temperature.

Solution—The work performed is $25.6 \times 33{,}000 = 844{,}800$ ft.-lb. per min. When the pump is in operation the pressure in the water-end is $0.434 \times 502 = 217.8$ lb. per sq.in. The diameter ratio being 2, the required steam pressure is $217.8 \div 2^2 =$ say 55 lb. per sq.in., gage or $55 + 15 = 70$ lb., abs.

From steam tables, water at 100 deg. F. contains 67.9 B.t.u. and steam at 70 lb. abs., 1179.9 B.t.u., per pound. Since this pump uses 64 lb. of steam a minute, the total heat in the cylinder is $64\ (1179.9 - 67.9) = 71{,}168$ B.t.u. per min.

Duty of pump, $\frac{844{,}800 \times 1{,}000{,}000}{71{,}168} = 11{,}870{,}500$ *ft.-lb.*

Inquiries of General Interest

An Electric Mine-Haulage Problem

I have been studying to become more familiar with the observed action of an electric mine locomotive, and am puzzled to explain to my own satisfaction the following question: Why will an electric mine locomotive pull more on series than on parallel? For example, should a motor stall on account of defective bonding when running on parallel, it will at once start and haul the trip if thrown over on series.

FRED VINTON, Mine Foreman,
Penn-Mary Coal Co.

Heilwood, Penn.

To answer this question intelligently, requires not only an intimate knowledge of the construction of the motor in use, but a thorough understanding of the principles involved in its action. The study of electricity is a difficult one, and there are many troubles continually arising that even expert electrical engineers find hard to fully explain.

The question correspondent has asked is interesting and worthy of careful study on the part of anyone in charge of an electric locomotive. In the present case, it may be assumed that the mine locomotive here referred to is equipped with two series-wound motors. These motors, on a locomotive or a trolley car, are usually arranged so that they can be operated in series when starting the motor and can then be thrown into parallel, after the motor has attained the desired speed.

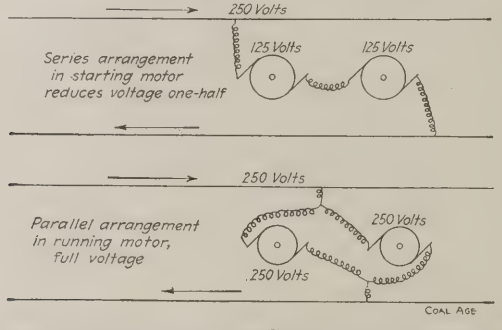

DIAGRAM SHOWING THE SERIES AND PARALLEL ARRANGEMENTS IN MINE MOTORS

Briefly stated, the object of this is to reduce the voltage one-half and thereby prevent the large rush of current that would take place in starting owing to there being, as yet, little or no electromotive force set up in the armature winding. As the speed of the motor is increased gradually, the electromotive force, which is then set up in the armature winding, opposes that produced in the motor field, with the result that the flow of current is restrained. Also, by means of the controller used in starting the motor, a gradually decreasing amount of resistance is introduced into the circuit, which likewise has the effect of regulating the current flowing through the motors.

The accompanying diagram illustrates both the series and parallel arrangements; and enables one to see more clearly how the voltage is reduced one-half, in the series arrangement; while the full voltage, disregarding the losses mentioned later, is available in the parallel arrangement. It is evident that when the total current is passing in succession through each of the motors, as in the series arrangement, each will absorb one-half of the voltage available at that point. For example, assuming the difference of potential between the trolley wire and the rail at the motor is 250 volts, each motor will be operating under one-half this pressure, or 125 volts in the series arrangement; while in the parallel arrangement each motor will be subject to the total pressure of 250 volts.

There are numerous sources of motor losses that in a direct-current, electric motor can be classified under three heads, as follows: (1) "Copper-loss" due to the resistance of the conductors on the armature and field windings, which in a well designed motor running under full load varies from 12 to 14 per cent. of the input, or less for a lesser load; (2) "Core-losses," which consist of the eddy-current losses that vary as the square of the speed of the motor, and the loss due to hysteresis that varies directly as the speed. Core-losses vary in different machines and result from the revolution of the armature laminations in a magnetic field, thereby producing eddy currents opposed to the field current of the motor. Hysteresis results from the tardiness of the magnetization in the metal, which, owing to the rapid reversal of current in the armature iron, considerably reduces the magnetic field; (3) Friction-losses in the bearings of the motor and the brushes and what is called "windage," due to the friction of the air against the revolving armature, which is slight.

Returning now to consider the power of a motor installed in a mine locomotive to pull its load, it may be stated that the tractive force or drawbar pull of the locomotive depends as much on the adhesion of the wheels to the rails as on the power exerted by the motor itself. Assuming, however, that the weight of the locomotive is such that its adhesion to the rails is sufficient for the power of the motors installed in the frame, it is only necessary to consider the torque or turning moment of the motors.

In a direct-current, series motor, this torque varies with the square of the current and is practically independent of the voltage, except as the losses to which we have referred, affect the speed of the motors, by decreasing the voltage. A lower voltage means a lesser speed, which reduces the losses but increases the available torque. By reason of this condition, motors operated in series possess a slight advantage in respect to torque, which measures the tractive effort of the locomotive. However, the chief advantage of the series arrangement in starting is the consequent reduction of the voltage one-half, which makes the expedient a valuable one in haulage.

Examination Questions

Firebosses' Examination, Held at Terre Haute, Ind., Sept. 10, 1914

(*Selected Questions*)

Ques.—If you were employed as fireboss, explain fully how you would conduct your examination of a mine for firedamp, from the time you commenced your work until you had completed it.

Ans.—I would reach the mine in time to begin work promptly, making sufficient allowance for properly inspecting and lighting my lamp and ascertaining that the ventilating apparatus was working as usual. Having descended the shaft or slope, I would proceed at once to follow the intake air from the point where it enters my district and to inspect in regular order all airways, passages and rooms, following the air current throughout the district.

When entering a room and approaching the working face I would proceed with caution to avoid walking into a body of gas, making such tests as are necessary to determine the presence or absence of gas. Every fireboss should, also, closely observe the condition of the roof and coal in each room to assure himself that the place is safe for workmen to enter. He should replace any brattice that may have been blown down by the shots discharged in that place. Having made this examination, I would mark the date on the face of the coal, as evidence of my presence at that point.

I would do the same at the face of each room and entry and then return to the shaft or slope bottom and enter in a book kept for that purpose my report of the examination, dating and signing the same. I would state in that report any particular dangers I had found. When making the examination I would place suitable danger signals and fence off any places found unsafe for men to enter. If the check system is in use at the mine I would remove from the board the checks of the men working in such places and deliver the same to the mine foreman, explaining to him the particular danger in each place. This would prevent any workman from entering a dangerous place unwarned.

Ques.—(a) What safety lamps do you know of that are in use, and which would you prefer to use in making an examination of a mine for firedamp? (b) Give reasons for your choice. (c) Explain the construction of the safety lamp of your choice.

Ans.—(a) The lamps most commonly used for testing for gas are the Davy and Wolf lamps. I prefer to use the common Davy lamp when making an examination for firedamp.

(b) The Davy lamp is simple in construction and very sensitive to the presence of gas. The lamp is convenient to handle, easy to clean and can be inspected in every part without trouble. It burns a nonexplosive oil and, when properly handled is a safe lamp to use.

(c) The Davy lamp consists of an oil vessel surmounted by a gauze chimney, which may be and usually is protected with a shield, to avoid the flame being blown through the gauze by a strong air current or heavy concussion of the air. The mesh of the gauze chimney contains 28 wires to the inch or 784 openings to the square inch. This chimney is 1½ in. in diameter and about 4½ in. high, in the fireboss Davy. The top of the chimney is further protected by a gauze cap, which is often called the "smoke gauze." The air supporting the flame enters the lamp in the lower part of the chimney and the gases produced by the combustion escape at the top.

Ques.—(a) If, on making an examination of a mine, you should find a large accumulation of firedamp at the head of a pair of entries where it had not been previously detected, to what cause or causes might this be attributed? (b) What precautions would you take to prevent an accident as the result of such an accumulation of gas?

Ans.—(a) The presence of the gas at the head of the entries might be due to the last shot fired at the face having opened a fresh feeder of gas either in the coal, the roof, or the floor. The shot may have caused a heavy fall of roof that has produced the same effect. In some cases, such a sudden accumulation of gas may result from a squeeze or creep extending over the head of the entries; but this is not possible except when the entries are in close proximity to other workings. Gas often makes its appearance suddenly when an entry strikes a fault and this may have produced the accumulation found in this case at the head of the entry.

(b) If the body of gas is large, no attempt should be made to remove it from the head of the entry, until all of the men working on the return of that current have been withdrawn. The gas should then be removed by starting a line of brattice from the outby corner of the last crosscut at the head of the entries and extending this gradually toward the face. As this brattice is extended, time should be given for the air current to sweep away the gas. Only safety lamps should be used in performing the work. While this test is being performed, every approach to the return current should be carefully guarded to prevent anyone entering the return airway with an open light or unwarned. If necessary, the air current should be increased sufficiently to enable the complete removal of the gas.

Ques.—Is it possible to increase the quantity of air circulating in a mine, without increasing the power producing the circulation; and, if so, by what means may this be accomplished?

Ans.—Yes. Without increasing the power producing the circulation, the quantity of air passing through the mine may be greatly increased by cleaning up the airways and removing every obstruction to the passage of the air current; also, by shortening the distance the air must travel; also, by splitting the air current one or more times, as this is found to be practicable. Wherever this is required, the crosscuts or breakthroughs should be enlarged to the full size of the entry, and all leaky doors, stoppings, brattices and air bridges made airtight.

Coal and Coke News

Harrisburg, Penn.

Final argument was heard recently, in the Dauphin County Court, in the mandamus proceedings brought against the chief of the Department of Mines on the issuing of certificates of eligibility to some of the men recommended by the mine foremen's examining boards, and in the injunction case brought by the United Mine Workers against the Chief of the Department of Mines from issuing certificates to certain men, who they allege never had actual experience at the face.

Involved in this suit is the question, whether the term "five years' practical experience as a miner" means five years' employment inside the mines, as was interpreted by ex-Attorney General Elkin (now Chief Justice of the Supreme Court) and by Attorney General Bell, during the early part of the year, or does it mean five years in the actual cutting of coal?

At the hearing held on Sept. 25, expert witnesses testified that the term "miner" in the anthracite region means the man who gets out the coal, but did not confine their opinion strictly to the cutting or blasting of that mineral.

Ex-Judge Shay argued that the court had no jurisdiction in the case, as it could not go behind the recommendations of the board appointed by the court, and cited the case brought by Thomas Reese against the Mine Inspectors' Examining Board of Schuylkill County, in which case the court decided it had no power to change the decision of the board. He also argued that the duties of the Chief of the Department of Mines were purely ministerial and that he had no right to hold up the certificates of the men recommended by the several boards, which is now being done until a decision is handed down in the injunction case.

Ex-Congressman Reilley, representing the United Mine Workers, argued that the word practical means a man who actually cuts the coal at the face, and that even expert witnesses testified that a man should have at least two years' experience at cutting coal at the face before becoming mine foreman. He stated that 70% of the fatal accidents in the anthracite mines occurred at the face, and that it is the man with the experience of cutting coal at the face that should become the mine foreman, so he would know how to advise and look after the man who is doing the most dangerous work, and the operator whose property he is in charge of, also to safeguard the people on the surface, who are liable to be affected by mine caves, due to an incompetent mine foreman.

Mr. Reilley also quoted as follows an article from one of the annual reports of the Chief of the Department of Mines, as to who should become mine foreman:

"One of the most important officials in the anthracite coal mines is the mine foreman. The welfare of the mining interests depends largely upon the vigilance, care and efficiency of these officials, and when they are incompetent, they are a menace to the lives of the miners and the property of the operators. The mine foreman should be qualified for his position, not only by practical experience in mining coal, but by experience in the other branches pertaining to mining operations. He should also be a man of good character and of necessity he must possess a high average of intelligence in order to pass the examination required by law—an examination that is or ought to be as stringent as a Governmental Civil Service examination. The mine foreman, it may be stated, is the only mine official of whom the law demands proof of qualification to perform the duties of his position; and in view of the responsibility that attaches to his position it is to be regretted that the examining boards are not more careful in passing upon the candidates for this office."

The attorneys for the United Mine Workers in their argument claimed that the interpretation of the law as given by the attorney general conflicts with the miner's certificate law which reads that a man must have at least two years' experience at the face before he can get a "miner's certificate" and in view of this law, that the legislature intended the word "practical" to mean the actual cutting of coal at the face. In reply to this Judge Shay stated that if that were the intention of the legislature, then the governor would have to go down into the mine and up to the face of the breast to select a chief for the Department of Mines, for the qualification of this office calls for "10 years' practical experience as a miner."

An early decision is expected in the case.

PENNSYLVANIA

Anthracite

Scranton—Headed by Rev. Roderick MacEachon, a Catholic priest who is active in the affairs of the local in which he has held membership for years, a delegation of union miners from eastern Ohio was recently in Scranton to confer with President John T. Dempsey and Secretary-Treasurer John M. Mack of the first anthracite district.

The miners of eastern Ohio have been on strike for months and appeals for aid are being made throughout the jurisdiction of the United Mine Workers of America. Miners from the Lehigh region contributed $3000.

Danville—The coal dredging season, the best in many years, is drawing to a close and already some of the dredges have ceased operating for the year. The first rise in the Susquehanna River will probably put an end to all the operations. The exceptionally fine season is due to the fact that throughout the summer there were frequent rains and as frequent rises in the river, with the result that the coal was brought down in large quantities.

Dupont—The officials of the Hillside Coal & Iron Co. have warned the property owners at the intersection of Ford and Williams Sts. that a cavein is expected. Ford St. is closed to traffic and employees of the Butler colliery erected fences at the Williams and Broad St. entrances. The residents have been warned to keep little fire in their stoves in case the settling may disturb their homes. Several weeks ago a cave occurred on Williams St. and carried down the tracks of the Scranton Traction Co. together with the brick pavement. On Oct. 13 a watchman discovered a cave in the Delaware & Hudson R.R. in Judge's Cut. It was about 40 ft. long and let down the northbound tracks several feet. Cars of ashes were rushed from Scranton, the hole filled, and traffic was resumed in a few days.

Port Bowkley—Considerable damage was done at Prospect colliery of the Lehigh Valley Coal Co., on Oct. 15, when the sheave wheel and part of the hoisting tower at the Prospect shaft were partially demolished, due to the cage being hoisted too high. The sprocket chain that runs the hoisting indicator broke and the engineer, who was hoisting a car of coal at the time, thought he could raise the car to the dumping chute in the head of the tower, without the use of the indicator. He mistook the distance and the overwind resulted. While repairs are being made to Prospect shaft all of the coal will be hoisted through the Oakwood shafts.

Shamokin—Six hundred members of the Shamokin and Mt. Carmel Mining Institute, including officials of the Mineral, Susquehanna and other coal companies, held a banquet at Maysville park on Oct. 17.

Audenried—It is feared that the first serious trouble since the signing of the agreement between the operators and men of the Lehigh & Schuylkill district may result from the action of the Lehigh & Wilkes-Barre Coal Co., in changing the powder used and raising the price at its No. 4 colliery.

Freeland—Trouble is said to be brewing between the stripping workers who belong to the United Mine Workers of America, and the steam shovel engineers' union. The latter are reported as having refused to recognize the former as union men despite the fact that they belong to the greatest union in the world. It does not sound reasonable that such a condition should exist when it is a positive fact that the stripping workers are now working for better wages and under better conditions than ever prevailed before they became affiliated with the U. M. W. of A.

Hazleton—By the breaking of a rope attached to the first car being hoisted over an inside plane in the shaft colliery of the Lehigh Valley Coal Co., the car ran away on the plane, dashed to the bottom and injured five men, before they could get out of the way. One of these men, Andrew McKelvey, of Hazleton, died soon after in Hazleton State Hospital from his injuries.

Tamaqua—When the Lehigh Coal & Navigation Co. agreed to reinstate four men discharged at the No. 11 Colliery pending a settlement of the grievances, 500 employees who went on strike recently returned to work.

Wilkes-Barre—The slate pickers of the Nottingham Colliery of the Lehigh & Wilkes-Barre Coal Co. recently went on strike for a longer work day, tying up the operations of the colliery. The breaker has been working on an eight-hour schedule, and the boys complain that their pay was too small.

Exchange—It is reported that a coal bed has been discovered on the farms of T. C. Dennis and William C. Houghton. This measure was discovered during well digging operations. It lies at a depth of between 70 and 80 ft. and ranges between 3 and 4 ft. in thickness. Preliminary tests go to show that it is a fair grade of anthracite.

Bituminous

Indiana—Austin Swartz recently transferred to the Operators' Coal Mining Co., of Johnstown, something over 135 acres in Wheatfield Township. This is a part of the coalfield that is now being developed by the Conemaugh Smokeless Coal Co., near Seward.

Connellsville—The coke trade has reached the lowest point of the year with shipments of 244,000 tons per week. Each coke seller is anxious to retain such trade as he has, and any extra coke that may be required is readily arranged for without a general inquiry being made. The coke market is, however, in apparently no worse condition than the local pig iron market which is entirely stagnant.

WEST VIRGINIA

Charleston—The Hitchman Coal & Coke Co. has announced its intention of making a special effort to have the Supreme Court of the United States review the action of the Circuit Court of Appeals in reversing the holding of the district court to the effect that the United Mine Workers is an unlawful organization. Judge Dayton, of the Federal district court of West Virginia, enjoined W. B. Wilson, now Secretary of Labor, and other officials of the United Mine Workers, from attempting to unionize the mines of the company named, on the ground that the organization was intended for an unlawful purpose. This holding was reversed on appeal, and while the coal company has no right of appeal, under the circumstances of the case, it believes the matter is sufficiently important to be passed upon by the Supreme Court, which may, in its discretion, review the case if it so desires.

The list of fatalities in the coal mines of West Virginia during the month of September shows that 30 miners lost their lives during the month, this being a decrease of 2 from the previous month. Falls of coal and slate were responsible for 16 deaths, nine were due to mine cars, three to motors, one to electrocution, and one man was killed by a railroad car at the tipple. Many of these accidents were caused by the carelessness of the men themselves, a lack of discipline on the part of the employees being responsible. Mine foremen are especially urged in the letter accompanying the report from the chief of the Department of Mines to give more attention to conditions at the working face and insist upon proper timbering.

The eyesight of all foremen and fire bosses in West Virginia is being tested so that they will be fully qualified to detect gas in any place in the mine which they may examine. An order to this effect was recently issued by Earle A. Henry, chief of the mining department, after a conference with coal operators throughout the state. The operators fully approve of Mr. Henry's ideas and advised him to issue the order, they promising their hearty coöperation.

Huntington—According to records of the Chesapeake & Ohio R.R., West Virginia and Kentucky coalfields for the first 13 days of October loaded 50,000 tons in excess of the amount loaded during the same period of last month. A total of 904,010 tons of coal was loaded from Oct. 1 to 13, inclusive, an increase of 50,165 compared with 853,845 tons loaded during the same period of last month. It is believed that should no unforseen contingency arise, the coal loading record will be broken this month.

Wellsburg—One of the largest coal deals ever consummated in Brook County was completed recently when Joseph and James Guida, operating under the name of Guida Brothers, sold their interests outright to Stephen Ertle of Pennsylvania and Leonard Wolfe of Brilliant, Ohio. The purchasers will continue to operate the mine. The coal property involved brought $100 per acre.

Bluefield—Judge H. C. McDowell in the Federal District Court in Lynchburg, recently entered a decree in accord with the recent mandate of the United States Circuit Court of Appeals at Richmond, awarding Mrs. Ollie H. Browning the sum of $61,875 in unpaid royalties and $96,816.75 unpaid purchase money for Tazewell County, Va., coal properties which have been in litigation in the Federal District Courts for several years. The decree was entered in the suits of Thomas Boswell against the Big Vein Pocahontas Coal Co. and the Colonial Trust Co., of Baltimore, against the same defendant.

KENTUCKY

Middlesboro—E. P. Nicholson and F. D. Hart, Jr., have announced that they have taken over the Low Ash Coal Co.'s property located near Excelsior, Ky. This is a shaft mine, one of two in this district, and opens into the Bonner seam, which yields a fine grade of coal. They are experienced operators and expect to begin shipping in a few days.

Central City—Some 600 miners in the employ of the Central Coal & Iron Co., in the mines both here and in Ohio County, were out of work for some time recently as a result of a disagreement between the union miners and officers of the company. The Central City mine previously was closed down for three months while a new tipple was in course of construction and other improvements under way at a cost of $50,000 and resumed work for only a short time before the disagreement developed. The Central company is not a member of the Western Kentucky Coal Operators Association and it therefore was not in position to arbitrate the differences with the Mine Workers. Work was resumed pending settlement.

OHIO

Warnock—The Youghiogheny & Ohio Coal Co.'s store at Warnock was recently robbed by two foreigners who are said to be miners. The robbery was not discovered until the store was opened in the morning, when it was immediately closed until bloodhounds could be brought from St. Clairsville. The dogs had but little trouble in finding a trail and soon took the sheriff to a house where the loot from the store was found, together with the two foreigners.

Glouster—A call has been been issued for a meeting of the miners of the Sunday Creek Coal Co. and the Pittsburgh Coal Co., to take place on Saturday, Oct. 31, for the purpose of agreeing upon some uniform system of weighing which will be in accordance with the provisions of the Ohio screen law. A straight run-of-mine system is desired, as at some mines a double draft system is used and at others a percentage is added to the screened lump. The miners assert that they agreed temporarily to permit the use of a weighing system other than that prescribed by the Green law, but that the operators have had time to comply with the law by this time.

ILLINOIS

Sparta—George and John Wilson, formerly connected with the Eden mine here, have leased the mine of the Boyd Coal & Coke Co. from the estate of W. R. Borders, who formerly operated it, but who lost his life in the Athletic Club fire in St. Louis the early part of the present year. The mine is being pumped out, and arrangements made for operation within the next 30 days.

Willisville—As a result of a feud between American and Italian miners at this place, which came to a head on the street here a week ago, two Americans and two Italians were killed. Feeling runs high, but the authorities contend that they can maintain peace.

Edwardsville—The Home Trade Co. of Edwardsville is the first coal mine in the United States to announce that Eagle trading stamps will be given with coal purchased at the mine. George D. Worden, superintendent of the mine, is determined to give this scheme a thorough tryout.

Livingston—Madison County has one of the largest and perhaps the greatest producing mine in Illinois. This is the mine of the New Staunton Coal Co. at Livingston, of which Thomas Hevenstreit is superintendent. During last year the mine worked 192 days and 7 hr. and averaged 4196 tons daily. The first two weeks of September this year showed an average of 4481 tons per day, and the last two weeks 4582 tons.

De Camp—The De Camp coal mine was recently sold by the master in chancery, Thomas T. Brewster of St. Louis, general manager of the Mt. Olive & Staunton Coal Co., bidding in the property. The latter would not disclose the identity of the purchaser for whom he was acting. Besides the actual coal mine equipment and coal rights to between 250 and 300 acres of land, the purchaser is also to receive 8 four-room cottages, and a two-story building suitable for use as a hotel or a boarding house.

MICHIGAN

Owosso—The Findley Coal Co., of Bay City, has secured control of the mines in New Haven Township, six miles north of Owosso, and is pumping out the shafts preparatory to resuming operations. These mines have not been operated successfully for 15 years. The Ann Arbor R.R. recently constructed a spur to them.

COLORADO

Denver—President Wilson is considering the advisability of withdrawing Federal troops from the Colorado coal fields as the result of the deadlock with the operators who refused to give approval to the President's plan for settlement of the strike. Governor Ammons is believed to be reorganizing the Colorado National Guard in order to make the presence of the Federal troops unnecessary.

WYOMING

Buffalo—The Owl Creek coal mine, which has not been worked recently, is on fire. Considerable volumes of smoke are issuing from the slope and the heat can be felt on the surface. This mine is valued at $300,000 and it is feared that it may be a total loss. Spontaneous combustion is supposed to be responsible for the fire.

PERSONALS

W. H. Blaney, of Cannelsville, Ohio, recently purchased a controlling interest in the Corning Mining Co.

John Turnbach has tendered his resignation as superintendent of the C. M. Dodson & Co. collieries at Bever Brook and Morea.

Joseph Tumkolkski, who was recently buried under a fall of coal in the Ebervale mine of the G. B. Markle Co., was rescued alive after six hours of entombment.

A. S. Tingley, a traveler with the Chapman Mining Co., has been made Ohio representative of the Commercial Coal Co. of Detroit. His headquarters will be in Columbus.

R. V. Norris, a consulting engineer of Wilkes-Barre, Penn., recently read a paper entitled the "Conservation of Anthracite Coal," before the engineering society of Wilkes-Barre, at the club room.

J. W. Reed, formerly mine inspector for the Consolidation Coal Co. in the Elkhorn District, has taken up his duties as Assistant State Mine Inspector. He was recently given the appointment by Governor McCreary.

Secretary B. F. Nigh, of the Michigan-Ohio-Indiana Coal Association, in his report for the month of September shows that in all 19 cases of freight collections were settled for the members of the association, which is the best month in the history of the organization.

A. Watts, one of the pioneer mine workers of Franklin County, Illinois, and who helped sink the Zeigler mine as well as those at Christopher, has resigned his position as manager of the Christopher mine, after several years of work, in which time he made this property the model mine in southern Illinois.

Effective Nov. 1. F. B. Lockhart of Cleveland, Ohio, president and general manager of the Baltimore & Ohio Coal Co., will be associated with J. H. Hillman & Sons Co., Oliver Bldg., Pittsburgh, Penn. Until other arrangements can be made by the Baltimore & Ohio Coal Co., Mr. Lockhart will continue to act for it as heretofore.

Charles H. Thompson, of Darbyville, Va., vice-president and general manager of the Darby Coal Mining Co. and the Old Virginia Coal Co., and W. J. von Borries, a mining engineer of Louisville, Ky., have leased from the Haly Coal Co. a tract of over 2000 acres of valuable coal land on First Creek of the North Fork of the Kentucky River, in Perry County, Ky., three miles from the Lexington & Eastern Branch of the Louisville & Nashville R.R., and are organizing a company to open and operate two large mines. A railroad will be built to the lease from the Louisville & Nashville.

OBITUARY

John Gallagher, a well known coal man in eastern Ohio and an official of the Ohio and Pennsylvania Coal Co., was killed by a fall of slate recently while cleaning up a mine at Yorkville.

Richard J. Hughes, a former auditor for the Pennsylvania R.R. Co. in Philadelphia, died at his home in Altoona on Oct. 16. He was born in Ebensburg, Cambria County. Mr. Hughes was extensively engaged in the coal business, and was 80 years old.

F. M. Beyea, aged 55 years, of Monroe Ave., Dunmore, Penn., land agent for the Pennsylvania Coal Co., died at his home on Oct. 13, following a stroke of apoplexy, sustained several hours before while riding in a trolley car. His father died in the same manner on an Erie train several years ago.

Charles Sutton, aged 47, a prominent resident of Homer City, Penn., and an official of the Buffalo, Rochester & Pittsburgh Coal & Iron Co., at Luzerne, was fatally injured Oct. 18, when the automobile which he was driving collided with a street car. The glare from the car's headlight apparently blinded Mr. Sutton, and he drove his machine directly into the approaching trolley. He died from the effects of his injuries early on Oct. 19.

PUBLICATIONS RECEIVED

The Canadian Mining Institute Monthly Bulletin No. 29, September 1914. Seventy-one pages, 6x9 in. illustrated.

Department of the Interior, Bureau of Mines, Miner's Circular 16. "Hints on Coal Mine Ventilation," by J. J. Rutledge. Twenty-two pages, 6x9 in., illustrated.

Department of the Interior, Bureau of Mines, Bulletin 76. "United States Coals Available for Export Trade," by Van. H. Manning. Fifteen pages, 6x9 in., with one map.

Department of the Interior, Bureau of Mines, Technical Paper 65. "A Study of the Oxidation of Coal," by Horace B. Porter and O. T. Ralston. Thirty pages, 6x9 in., with numerous curves, drawings and diagrams.

Department of the Interior, Bureau of Mines, Bulletin 83. "The Humidity of Mine Air with Special Reference to Coal Mines in Illinois," by R. Y. Williams. Sixty-nine pages, 6x9 in., with numerous tables, curves, and illustrations.

West Virginia Geological Survey, County Report for 1914, "Preston County." Cloth-bound volume of 566 pages, containing many halftones and tables. This volume is accompanied with a case of three maps showing the region in question.

The University of Illinois, Engineering Experiment Station, Bulletin No. 75. "Thermal Properties of Steam," by G. A. Goodenough, 69 pages, 6x9 in., with numerous curves. In this bulletin is described the development of a general theory of the properties of superheated and saturated steam. The equations employed are true throughout a range from 32° to 600° F., or a far wider limit than is at present employed in engineering practice.

TRADE CATALOGS

Morgan Gardner Electric Co., Chicago, Ill., Catalog 57, "Mining Locomotives." Forty pages, 10x7 in. illustrated.

Morgan Gardner Electric Co., Chicago, Ill., Catalog 55. "Continuous Coal Cutters." Thirty-two pages, 10x7 in., illustrated.

The Goodyear Tire & Rubber Co., Akron, Ohio. "Mine Equipment, Belting, Packing, Hose, Valves." Twenty-eight pages, 3½x6¼ in.; illustrated.

The Walter A. Zelnicker Supply Co., St. Louis, Mo. Bulletin No. 159, September, 1914. "Opportunities in Used Equipment." Eighty pages, 3¾x8¼ in.; illustrated.

Manistee Iron Works Co., Manistee, Mich., "Centrifugal Water Pumps, Rotary Jet Condensers and Air Pumps." Seventy-two pages, 8x10½ in. illustrated.

Link Belt Co., Philadelphia, Chicago, Indianapolis. "Link Belt Locomotive Cranes." Thirty-eight pages, 8½x11 in., illustrating the adaptation of the locomotive crane to the handling of various materials.

RECENT COAL AND COKE PATENTS

Smoke Precipitator. C. W. Lent, Byron, Calif., 1,103,304. July 14, 1914. Filed May 26, 1913. Serial No. 769,836.

Locomotive Stoker. N. E. Gee, Altoona, Penn., 1,103,406. July 14, 1914. Filed Oct. 15, 1912. Serial No. 725,960.

Furnace Grate. F. L. O. Wadsworth, Sewickley, Penn., 1,103,232. July 14, 1914. Filed Sept. 30, 1912. Serial No. 723,075.

Furnace for Boilers. R. F. Sturrock, Dundee, Scotland, 1,103,098. July 14, 1914. Filed Mar. 12, 1912. Serial No. 683,353.

Water-tube Boiler. W. D. Hoxie, assignor to Babcock & Wilcox, Bayonne, N. J., 1,102,407. July 7, 1914. Filed Jan. 12, 1912. Serial No. 670,750.

Boiler Arch Construction. E. P. Stevens assignor to Locomotive Arch Brick Co., Chicago, Ill., 1,103,447. July 14, 1914. Filed June 28, 1913. Serial No. 776,234.

Safety Apparatus for Mining Cages. S. W. Richardson and W. Stavely, Hokitika, New Zealand, 1,103,841. July 14, 1914. Filed May 7, 1913. Serial No. 766,180.

Process and Apparatus for the Treatment of Coal and Shale in Vertical Retorts. A. Waddell, Dunfermline, Scotland. 1,103,112. July 14, 1914. Filed Sept. 11, 1913. Serial No. 789,306.

CONSTRUCTION NEWS

Indiana, Penn.—Work has recently been started on the survey on the Calderwood farm for a new coal opening.

Bakerstown, Penn.—The Sterling Coal Co. is putting into service two 12-ton barsteel locomotives recently ordered from the Westinghouse Electric & Mfg. Co.

Raven Run, Penn.—The Girard Mammoth Coal Co. recently ordered another 12-ton Baldwin-Westinghouse locomotive in order to handle its haulage problem more efficiently.

Charleston, S. C.—Work has been begun on the half million dollar coal plant which the Southern Ry. is erecting on the Cooper River, in the rear of Magnolia Cemetery.

Barnesboro, Penn.—The new tipple at the Marion mine of the Madeira-Hill Coal Mining Co. has recently been completed, and coal is now being shipped from the new structure.

Wilkes-Barre, Penn.—The Mill-Creek Coal Co. has awarded to C. K. Schupp of Wilkes-Barre, a contract for a large stripping operation, which will uncover thousands of tons of coal.

Johnstown, Penn.—H. E. Northens, of Johnstown, has purchased, with others, 63 acres of coal land at Bull Creek, near Tarentum. A modern tipple is to be erected at the mine which will be opened soon.

Mt. Carmel, Penn.—The Westinghouse Electric & Mfg. Co. recently received an order for four 10-ton barsteel locomotives from the Philadelphia & Reading Coal & Iron Co., to be placed in service at the latter's Alaska colliery.

Athens, Ohio—The Hocking Power Co. is busy on the construction of the pole line which will carry its distributing system from the Floodwood power station to the various mines and towns which will take current therefrom. The machinery is all in place, and it is expected shortly that the latter will be put in operation.

Lansford, Penn.—The Lehigh Coal & Navigation Co. is installing at Nesquehoning and Seek, Penn., two 250-hp. Westinghouse synchronous motors direct connected to air compressors which replace steam driven units. The current for these installations comes from the Hauto plant of the Lehigh Navigation Electric Co.

East Liverpool, Ohio—The Sugar Camp Coal & Clay Co., headed by J. J. Smith, who has for many years been connected with the Pittsburgh Coal Co., has taken leases on 500 acres of land extending from the eastern corporate limits of Chester up the river to Mill Creek. A corp of mining engineers was recently started at the work of testing out and proving the coal deposits.

NEW INCORPORATIONS

Hartford, Ark.—The Blackburn Coal Co. has been incorporated here, with Lillie Blackburn, president, W. A. Blackburn, vice-president, and C. M. Blackburn, secretary and treasurer.

Chicago, Ill.—The East Kentucky Coal Co. has been organized to develop 2500 acres of coal land near Richardson, Ky. The daily output of the mine will be 2000 tons.

Tacoma, Wash.—The Cassidy Coal Mine Co. has been organized at Tacoma with a capital stock of $1,000,000, by J. L. McMurray and R. L. Sherrill. W. D. C. Spike is attorney.

Bramwell, W. Va.—The Cooper-Pocahontas Coal Co. has been organized with a capital stock of $70,000 for the purpose of operating coal mines in southeastern West Virginia. The incorporators are W. B. Honaher, of Matoaka, E. Cooper, C. H. Thomas, and W. A. Thomas, of Bramwell, and J. G. Thomas, of Mullins.

INDUSTRIAL NEWS

Penowa, Penn.—The Waverly Coal & Coke Co. has opened a new mine at Penowa, which, when developed, will give employment to several hundred men. William Fleming, of Virginville, W. Va., is superintendent of the new operation.

Moundsville W. Va.—An important coal deal was recently consummated at Moundsville, eastern Ohio operators securing a controlling interest in the Parrs Run mine. This mine is in operation, and will be continued so, the coal going to the markets formerly supplied by the territory across the river.

Scranton, Penn.—An agreement has been entered into between the Northern Coal Co. and the supervisors of Fell Township, whereby the company is to build and maintain the township roads in lieu of road taxes. The company has been taking care of the roads for years, and the arrangement has always worked satisfactorily.

Columbus, Ohio—The Hocking Valley Ry. Co. has asked permission of the State Public Utilities Commisison to issue $4,000,000 of one year 6 per cent. gold notes, the proceeds to be used in refunding a similar quantity of outstanding notes due Nov. 1. The company stated that it was unable to indicate what price it would be able to get for the issue, on account of the financial situation.

Toledo, Ohio—The receivers for the Cincinnati, Hamilton & Dayton R.R. Co. have filed a petition in the United States District Court to secure authority to transfer a portion of the holdings of the company in the Toledo Terminal R.R. Co., of Toledo, to the Hocking Valley Ry. Co. and the Toledo & Ohio Central R.R. Co. The object is to equalize the holdings of the railroads entering Toledo in the terminal belt line.

Washington, D. C.—The Alaska coal land leasing bill, revised at the instance of the President and Secretary Lane as part of the Administration's program for this session, awaits only the President's signature to become law. This bill is designed to open by a system of leases under competitive bidding the immense coal resources of Alaska, tied up for the last 8 years. Pending claims will be adjusted within 12 months.

Columbus, Ohio—Clarence D. Laylin, assistant to Attorney General Hogan of Ohio, has filed a petition in the United States Supreme Court asking for the dismissal of the application now pending for a restraining order against the operation of the Ohio anti-screen law. The case was brought to the attention of the court at the last term when an application for the interlocutory injunction, filed in the U. S. District Court in northern Ohio was denied.

Scranton, Penn.—An order was recently issued for a parade of the mine workers to take place on Mitchell Day, Oct. 29, in the city of Scranton. The parade will begin at 1:30 o'clock and there will be a mass meeting immediately after in the baseball park. Addresses will be delivered by former president, John Mitchell; Stephen MacDonald, John P. Dempsey, Joseph Yaunis, and Alex. Kupstas. This will be the 14th anniversary of Mitchell Day.

Cairo, Ill.—The tow boat "Joseph B. Williams" was recently destroyed by fire at this point. When this vessel was built she was the largest craft of the kind in the world, and remained so until the steel-hulled tow boat "Sprague" was built for use on the Mississippi River. The "Joseph B. Williams" held the record of being the biggest wooden-hulled tow boat in existence until her destruction. She was built at Freedom, Penn., in 1876. She was 252 ft. in length, with a beam of 52 ft., and belonged to the Monongahela River Coal & Coke Co.

Columbus, Ohio—That Columbus is expected to become a great coal and ore center is suggested by the vast constructural program being pushed by the Hocking Valley and the Chesapeake & Ohio railroads. The city will be the terminus of a new line being built by the latter road as an outlet for the coal fields of West Virginia, Kentucky and Ohio. It will also be the transfer point in a scheme for the distribution of these fuels, and also the ores from the Northwest. The new road will connect with the Hocking Valley, which latter will double-track its line northward to the Lakes.

Coal Trade Reviews

General Review

Anthracite trade slowing up, due to the warm weather, and concessions on the circular are freely offered. Further restrictions and cancellations are the features of the bituminous market. Practically no spot demand.

The anticipated active business, succeeding the cold spell of early September, has failed to materialize because of the return of higher temperatures. The slowing up applies more particularly to the retail end, the wholesale business still being in a healthy condition; in fact, were it not for the mild season there would already be considerable anxiety about getting cargoes forward. The individuals are offering concessions down to as low as the May circular on some grades, while occasional cancellations are noted, and a continuance of the summer-like weather may necessitate a curtailment in mining operations. The heavy pressure for stove coal has entirely disappeared and straight cargoes of any reasonable amount are now readily available at the circular.

Further recessions are noted in the bituminous market in spite of the fact that it has been repeatedly felt that the bottom had been reached. Restrictions and cancellations on contracts are noted, while demurrage coal is beginning to appear, and there is a complete absence of any spot demand. The export business has been particularly disappointing. There are still some inquiries for foreign shipments, but the movement over the piers is light and confined almost entirely to contracts; exports are practically nothing insofar as any relief from the prevailing depression is concerned. Accumulations at the large distributing centers are reaching larger proportions, and the only thing that prevents a heavy slashing of prices is the general conviction that even this would not stimulate any buying.
